* The law referred to recognizes the fact that all ordinary striated skeletal muscles are directly connected with, abundantly permeated by, and called into action through the mediation of nerves; and, furthermore, that, so long as the muscle retains its irritability, and the nerves connected with it preserve their conductivity, nerve stimulation must result in muscular contraction. Taking this physiological law for our guidance, and, bearing in mind the teachings of Mr. John Hilton and Schroeder van der Kolk, it is easy to account for the phenomena of reflex muscular spasm in hip and other allied articular diseases, on the ground that the delicate nerve filaments which are supplied to the muscles moving the diseased joint are derived from the same source as those passing into the area of bone involved by the disintegrating inflammation, and that these latter are unduly pressed upon or otherwise irritated, which irritation is transmitted along the course of the nerve-fibers to the muscles, giving rise to their involuntary contraction (shortening).

It may here be remarked that the explanation of the subduction of reflex muscular spasm by the application of a firm roller bandage, as referred to in a previous foot-note, over the contracting muscles, is to be found in the fact that the circumferential pressure thus exerted prevents the transverse bulging of the muscles—a necessary concomitant phenomenon of muscular contraction (shortening).

accomplish this, but from effectually supporting the disabled member with a resilient prop. Hence, to make the supporting part of our mechanical appliances out of *rigid* substances, with the avowed end in view of "absolutely fixing" the joint, can not be the result of a legitimate or logical interpretation of the fact just cited.

The Fixation Dogma abrogated and Linear Traction with Motion substituted.—But to continue with the examination of our little patient. While we hold the limb still in nearly the same position and make gentle traction in the line of the deformity, in conjunction with circumfemoral manual compression, he gradually, as already observed in our preliminary or non-critical examination, experiences a still greater degree of relief, and there is a partial or complete subsidence of the reflex muscular spasm. Not only have I rendered my patient much more comfortable than he previously was, but I now find that I can do with perfect impunity what was before absolutely impossible—viz., *make moderate movement of the affected articulation, and that too without the slightest discomfort to the patient*. Having overcome the reflex muscular spasm, I find, furthermore, that the amount of motion permitted is largely determined by the extent of *intra-* and *extra-articular* inflammatory infiltration. The greater the bulk of these products, the more do they act as a mechanical barrier to motion of the joint.

Methods adopted for the Co-employment of Traction and Motion.—When the correctness of the foregoing observation had been established by numerous tests, there arose the idea of permitting motion of the joint during the continuance of linear mechanical traction. This observation was the signal for renewed exercise of mechanical ingenuity, and the avalanche of novel devices which followed bears emphatic testimony to the eagerness with which such opportunities are embraced. In the mechanical execution of this idea the changes have been pretty thoroughly rung on segmented enveloping splints and non-enveloping jointed splints, with or without crutches, all of which have provision for exerting linear traction and permitting more or less freedom of articular motion. Critically analyzing the quality of the force exerted by these appliances, we again see, as in the former instance, that in nearly all *rigid traction* has been substituted for *manual traction*, which, unlike the former, is resilient, tensile, elastic.

Recapitulatory Review of Mechanico-Therapy, and Summary of Conclusions based upon the foregoing Clinical Phenomena.—From our present standpoint we are able to see that that which was accomplished in our efforts to relieve the patient was not "fixation of the inflamed joint," but the affording of adequate though resilient support, it being physically impossible to immobilize the joint by manual efforts. It was thus demonstrated, by the simplest kind of an experiment upon the living human being, that the idea of "fixing" the joint, which has gained such a firm hold upon the professional mind, has no foundation whatever in the clinical evidence adduced.

Had this analysis of the quality of the force exerted by human hands been made before surgeons began to devise means to mimic it, *rigid* splints would have been less commonly used. The tensile (elastic) support rendered by

human hands, and demonstrated, as every practical surgeon knows, by thousands of satisfactory tests, to be so acceptable to the hip-diseased patient, would never have been supposed to have been successfully imitated by the use of such substances as plaster of Paris, iron, etc., made into heavy splints capable of affording only *rigid* support. The fixation dogma would have been nipped in the bud, and mechanical surgery would not have been throttled at its outset by the false interpretation of a commonplace fact.

In the second place, manual traction, like manual support, is resilient, tensile, elastic. In the execution of this idea by mechanical appliances, a fatal error becomes manifest. The tensile (elastic) linear traction exerted by the hands of the surgeon and repeatedly demonstrated to be all-sufficient for the relief of the patient, and for the rapid subduction of reflex muscular spasm, has, without its quality being analyzed, been replaced in nearly every instance by stiff iron or steel bars, the fixed points of which are separated by a screw, or by means of a ratchet and key, or by slotted bars held together by a screw and nut—mechanisms capable of exerting only *rigid* traction.

Thirdly, on taking hold of the limb of our patient, thoroughly supporting it, and making gentle traction in the line of the deformity, it was found that even an approximation to the immobilization of the joint was unnecessary to the comfort of the patient. Hence it was that surgeons who appreciated this fact sought to make use of it by permitting motion of the joint during the application of mechanical traction. Their object was to avoid the damaging influence of the long continuance of a close approximation to fixation of the joint, and especially the occurrence of ankylosis, a result almost certain to follow continued efforts of this kind in the treatment of chronically inflamed joints, the articular surfaces of which have become eroded. Here, again, surgeons, in nearly every instance, have clung to the enduring fallacy of substituting a rigid or non-elastic force for that exerted by the hands. By permitting motion, as has been done, under the influence of *rigid traction*, the results in some cases have been much more disastrous, in my opinion, than those incident to the employment of rigid fixation splints, or, at least, the employment of those that “fix” and rigidly tract the joint. My reasons for holding this opinion are as follows:

The articular surfaces of joints are not perfectly regular in outline. In health, the surface, though smooth, usually has an undulating contour. The hip joint, it is true, presents surfaces of nearly regular outline, and it is on this account, as will appear further on, that results in hip cases have been almost exclusively adduced in favor of the co-employment of rigid linear traction and articular motion. In moving the joint under the influence of *manual* traction and support, the tensile force exerted permits of the shaft following or adapting itself to the normal articular contours. Not so, however, when motion of the joint takes place under the restrictions of rigid *mechanical* traction. Under these circumstances we have a fixed point above and below the diseased articulation. Between these two fixed points extends a longitudinally adjustable rigid bar with a hinge opposite the affected joint. Increasing the

distance between the two fixed points by lengthening this rigid bar in its adjustable portion will cause it to exert *rigid linear traction*. If now, during the continuance of rigid mechanical traction, the diseased joint be moved, it is plain to be seen that the articular surfaces can not perfectly adapt themselves to each other, for the force exerted by the instrument is rigid, and will not permit of motion outside the narrow limits prescribed by the mechanical hinge of the splint. As the path of motion permitted by the joint of the splint does not exactly coincide with that demanded by the affected articulation, in order that motion shall not be disastrous to its integrity, there result, necessarily, more or less intra-articular pressure and friction from its movement under such circumstances.

It may have been the appreciation of this fact which led Dr. D. Hayes Agnew to dogmatically assert that “motion without articular pressure or friction is simply impossible, and it is not in the power of man to make it otherwise.” If *rigid* splints were our only means of making traction and permitting articular motion, I would willingly subscribe to the declaration of Dr. Agnew. But such is not the case. Instruments have already been devised and placed at the disposal of the profession which permit of articular motion under precisely analogous conditions to those demonstrated by an examination of the patient to be necessary in order that it should take place without giving rise to the least discomfort.

In view of these facts, it is rather remarkable that so sagacious an observer as Dr. Lewis A. Sayre should make the fatal error of substituting *rigid* mechanical traction for *tensile* manual traction. More especially is this the case in view of the fact that his advocacy of articular motion, in conjunction with mechanical traction, is based upon the identical observation to which I have already called attention, viz.: *that, during the continuance of efficient manual support and traction, movement of the affected joint can be made without causing the least discomfort to the patient.*

We have, then, as a natural outcome of a mistaken interpretation of clinical facts, and at a great outlay of time, labor, and money, a system—nay, more, systems—of mechanical appliances which, in the light of the foregoing observations, would appear to be wholly illogical and irrational. By the moderate exercise of our critical faculties we have now robbed the pet ideas *fixation* (rigid support) and *extension* (rigid linear traction) of their former cogency. We have shown that, if we are to make use of the evidence admissible from an examination of the patient as a basis for therapeutic procedures, we must first be certain of the *facts*, and, having demonstrated the reliability of these, should proceed to correlate them by finding out the thought which binds them together.

A brief but valuable lesson in the terminology of mechanico-therapy has been another result of our inquiries. It has been shown that the words support, traction, etc., can no longer be safely or legitimately used as specific terms, but must henceforth, as a result of an advance in knowledge, rank as *generic* terms, requiring qualification when used by such words as rigid, fixed, manual, elastic, tensile, linear, etc.

Again, in drawing our recapitulatory review of clinical

phenomena to a close, we are brought face to face with the unpleasant reality that confidence in the prevailing systems of mechanical therapeutics as applied to hip disease is no longer justifiable.

Finally, we have deduced from clinical sources the following demonstrable facts:

1. That adequate resilient force can be applied to the affected limb of the hip-diseased patient without his experiencing in consequence thereof a feeling of irksomeness.

2. That artificial support the quality of which is tensile (not rigid) is that which is indicated from an examination of the patient as desirable to be employed.

3. That resilient circumferential compression is a potent factor in overcoming or preventing reflex muscular spasm, and probably has more to do with its nullification than "fixation" of the joint, or even simple resilient support.

4. That elastic linear traction is the only kind or quality of traction that has been demonstrated to be serviceable from an examination of the patient, and that it is fully adequate to the rapid subduction of reflex spasm.

5. That the combined use of efficient resilient support, firm tensile circumferential compression, and elastic linear traction, renders the patient more comfortable and more quickly subdues reflex spasm than the independent use of any one or two of these measures; and that, during the continuance of their conjoint use, articular motion can be made without the slightest discomfort to the patient, the extent of such motion being largely dependent upon the bulk and consistence of the inflammatory products in and around the joint.

Therapeutic ideas based upon the above-mentioned facts would not be open to the serious objection of being illogical, irrational, and unscientific. But can we find no further evidence than that deducible from clinical sources with which to strengthen our developing therapeutics?

(To be concluded.)

A CASE OF SUDDEN DEATH FROM PRESSURE ON AN INFLAMED PNEUMOGASTRIC NERVE.

By HENRY D. CHAPIN, M.D.,

ATTENDING PHYSICIAN TO THE OUT-DOOR DEPARTMENT, BELLEVUE HOSPITAL
(CHILDREN'S CLASS).

SUDDEN and unexpected death in the midst of apparently light illness is an event at once appalling to friends and distressing to the attending physician, who, unless able to give a ready and satisfactory explanation of the accident, too often suffers unjustly in reputation. It is thus extremely important, in the interests of the profession, that a careful investigation of all such cases be made, and any cause of death be recorded that may be somewhat uncommon and thus liable to be overlooked. It is often much easier in public than in private practice to obtain autopsies and study out obscure manifestations of disease. The following case that came to my clinic at the Out-door Department of Bellevue Hospital was one of great interest to me, inasmuch as I was unable to make a diagnosis during life, and found

a condition after death that would have been impossible to treat, even if I had been able to recognize it.

Mary D., aged two years and eleven months, was brought by her mother to the dispensary September 5, 1883, to be treated for a slight cough. A physical examination of the lungs proved negative, and I should have dismissed the case as one of simple catarrhal tracheo-bronchitis had not a peculiar sound during respiration attracted my attention and led me to study the case more carefully than is usually practicable in a large dispensary service. The child was well nourished, and quite large for her age. The only point in a good previous history that seemed to show any constitutional taint was the fact that she had reached the age of eleven months before getting her first tooth. The mother stated, however, that she had always been healthy, and when I examined her there was nothing suggestive of a rachitic appearance. Five months before she had an attack of pertussis, and had coughed some ever since. Occasionally she would have some wheezing. The peculiarity about the case was an obstructive sound, heard plainest on inspiration, that could be recognized at a little distance from the child. It was somewhat suggestive of croupy breathing, and yet not exactly like any I have heard. There was not the slightest dyspnoea accompanying this obstruction. An examination of the throat by the finger revealed no swelling or abscess that might have escaped the eye. The temperature was normal. There was no appearance of diphtheria in the fauces, but, fearing an insidious form of diphtheritic croup low down in the larynx, that, although at present causing no inconvenience, might suddenly develop urgent dyspnoea requiring tracheotomy, I directed the mother to keep close watch of the child and report to me at once any untoward symptoms. I was somewhat surprised when she appeared with the child on my next dispensary day, stating that she was just the same, no better and no worse, but with the same peculiar sound in breathing. For the next few weeks she was brought at stated times to the dispensary, and seemed to improve under tonics and simple expectorants. The cough, which had never troubled her very much, was getting a little better. I had excluded the idea of the existence of any pseudo-membrane by the entire absence of dyspnoea, and the fact that the voice was never interfered with in the slightest degree. There had never been any dysphagia. The last time I saw her was on October 8th, when she seemed in a very fair condition, and her mother thought it would not be necessary to bring her any more. The tracheal or laryngeal râle also seemed not quite so distinct. I had taken her temperature a number of times, and always found it normal. On October 10th the mother came to my office in great distress, saying that her child had died very suddenly the previous evening. She ate a hearty supper at six o'clock, after which she seemed in unusually good spirits, laughing and playing with her mother. About 8 P.M. she was taken with a paroxysm of coughing, in the midst of which she was suddenly seized with intense dyspnoea, grew rapidly cyanotic, and rolled over on the floor dead. The breathing had not troubled her in the slightest all day, and her voice was as perfect as ever up to the time when she was attacked by the fit of coughing that just preceded her death. The entire absence of dysphagia up to the last was shown by the fact that the child ate and relished a hearty supper two hours before she died.

Autopsy.—Child well nourished. In order to remove the food and air passages without disturbing their relations any more than possible, I removed the lungs from below, and, cutting across the œsophagus, stripped it up from the vertebral column. While proceeding cautiously in this manner, a large quantity of pus suddenly appeared from the rupture of an abscess situated back of the upper part of the œsophagus. On examining this more

carefully, I found that the abscess was placed within and in front of the first and second dorsal vertebra, which were deeply carious. In fact, all that was left of the bodies of these bones was a mere shell, inclosing masses of dead bone, but the spinal canal had not been invaded. The inner surface of the œsophagus was healthy-looking and intact. The rupture of the abscess had evidently been caused by the removal of the œsophagus, which dragged open the sac.

Miliary tubercles were found scattered through the lungs, also in the trachea, which was injected and covered by mucopus. Just below, and to the right of the abscess, was seen a large and hard cheesy bronchial gland. Between this enlarged gland and the sac of the abscess, which were in close apposition, the right pneumogastric nerve passed and was compressed just where the cardiac plexus of nerves was given off. Just above this position the vagus appeared swollen.

In order to determine exactly the condition of the pneumogastric nerve, I gave the specimen, which had been removed entire, to Professor Welch, who has given me the following as the result of his examination: "A portion of the pneumogastric nerve was removed which was adjacent to a tuberculous abscess and a caseous bronchial gland. To the naked eye, in this region the nerve appears somewhat swollen. The swelling is fusiform in shape. Upon section, the nerve appears gray in color and rather firm in consistence. Examined microscopically, the nerve is found to be the seat of a chronic interstitial neuritis. The whole nerve is surrounded by dense fibrous tissue, which is prolonged into the interior of the nerve in bands which separate the nerve fibers into large and small bundles. Some of the nerve fibers have disappeared, others are atrophied, and others appear normal. The newly-formed connective tissue is rich in lymphoid cells."

The condition here described offers, I think, a satisfactory explanation of the phenomena observed in this case. The inflamed pneumogastric nerve was subjected to continuous pressure between the enlarged gland and the sac of the abscess. During coughing this pressure must have been intensified, probably by a sort of pounding motion, which was sufficient in the last paroxysm to produce sudden cardiac paralysis. The interstitial neuritis of the vagus may have been originally started by pressure, or the inflammation may have spread to the nerve by contiguous inflammatory irritation from the surrounding tubercular tissue. Ross, in his recent work, gives, among other causes of neuritis, strong compression of a nerve and extension of inflammation from surrounding tissues and organs. He states that pleurisy, pleuro-pneumonia, and tuberculosis of the lungs have caused inflammation of the intercostal nerves, as proved by Bean. Under affections of the pneumogastric nerve, he states that the trunk of the vagus is liable to be injured by compression or secondary implication from tumors of the lymphatic glands, abscesses in the neck, or aneurysm of the larger arterial trunks in the chest and neck. He also states that, when the phenomena of irritation of this nerve predominate, the action of the heart is rendered slow and irregular. If there be paralysis of the vagus, however, either unilateral or bilateral, there will be an increase in the frequency of the pulse, which may beat permanently at the rate of 120 to 160 a minute. Lastly, in pure compression of the vagus, death may result from syncope caused by irritation of the inhibitory fibers of the pneumogastric.

It appears, then, that, when the pneumogastric nerve is

irritated or excited by mechanical or other agents, there is slowing of the heart's action, but sudden and complete paralysis may follow if the excitation is too severe. The latter was evidently the cause of death in my case. As no continuous record was kept of the pulse, I am unable to state whether there was any previous slowing of the heart. As nearly as I can recollect, the pulse was about normal when I first saw her. In fact, there was nothing in the case to draw any special attention to the heart's action, as both the pulse and temperature were normal at first. The peculiar obstructive râle heard during respiration had evidently been caused by the abscess pushing forward the œsophagus and encroaching somewhat on the trachea, but not enough to cause any dyspnea. There was no dysphagia, as the œsophagus, which allows of distension, and is surrounded by connective tissue, was subjected to pressure only from behind. Dr. Ripley has lately reported a case in which a gradually increasing and fatal dyspnea was caused by a retro-œsophageal abscess pressing on the recurrent laryngeal nerve ("Archives of Pædiatrics," vol. i, No. 2), and different authors have recorded many cases of dyspnea and spasmodic cough caused by enlarged bronchial glands encroaching on this nerve or on the bronchi; but I have not seen any case recorded in which a gland or abscess produced irritating effects on the cardiac portion of the vagus without involving any other part of the nerve or seriously encroaching on some adjacent structure.

217 WEST FORTY-NINTH STREET.

REMARKS ON EXCISION OF THE ANKLE JOINT, WITH SPECIAL REFERENCE TO TECHNIQUE AND AFTER-TREATMENT.*

BY F. LANGE, M. D.

MR. PRESIDENT AND GENTLEMEN: I am going to present six patients in whom I have excised the ankle joint more or less extensively within the last two years. In five of these cases the operation was done for scrofulous disease. The patients were at the time of the operation from one and a half to nine years old. In one case a gunshot injury gave the indication. The patient is eighteen years old. I shall omit to ventilate the question, how far there is the indication to excise the ankle joint for scrofulous disease. Certainly a great difference of opinion exists regarding this point. A good many surgeons, especially in England and America, are in favor of expectative treatment. During six years of living in New York I have not seen a single excision of the ankle joint except one, which, strictly taken, was no excision; nor have I heard of one; and I am perfectly aware that in children a great deal can be achieved by mere expectative treatment. On the other hand, I hope to prove by my cases that very good results can be reached by excision, that the disease in some cases is undoubtedly shortened by years, and in one or the other may have saved the limb. The prejudice prevailing against excision is mostly based, I

* Read before the New York Surgical Society, February 26, 1884.

believe, on deficient knowledge of good after-treatment, and to some degree on inattention to the technique. To these two points I shall principally direct your attention.

Regarding the operative procedure I do not offer anything new. The genius of Langenbeck has presented a method which, in spite of all new, more or less sensational modifications, is by far the best in every respect. It causes the least injury, gives the best guarantee for new formation of bone, if that can altogether be expected, and allows of sufficient insight over the field of operation. To make the operation still more strictly subperiosteal, I remove the periosteum, in all those places where ligaments or tendons are attached, by means of a chisel. In small children, where the epiphysis is mostly cartilaginous, free use can be made of the knife. The bones are removed by means of a sharp chisel also; eventually a cross-cut is made through the periosteum of the tibia below the line of intended separation, to obviate tension and to allow of free access for the chisel. In this way also superfluous denudation of the bone is avoided. The chisel must be sharp and thin, and form, by means of numerous small cuts, a smooth perpendicular surface on the cross-cut of the bone remaining—to be sure, at the expense of the specimen. I always unite the periosteum-cylinders by a few catgut sutures. In all cases the fibula has been excised also. In the traumatic case the astragalus was left untouched, in one case only its articular surface has been removed, in four it has been removed entirely. In one case complete *evidement* of the os calcis was added. I need not say that antiseptic principles, with the permanent antiseptic dressing, decide the wound treatment. The limb is suspended by a long, anterior plaster-of-Paris splint, after the manner of Beely, into which iron rings are fastened. It reaches as far as the middle of the thigh, and keeps the knee in a somewhat flexed position.

Great care must be taken during the wound dressing to keep the foot in such a way that it is not too much pulled forward. The assistant who holds the foot is very apt to commit this blunder. In this way the axis of the bones of the leg falls behind the intended point of the new joint, and you will see in some of my cases that I have not been entirely able to overcome this deficiency. In cases where the whole astragalus has been removed that might not be any disadvantage, because the bones of the leg are then supported by a part of the os calcis which is lying more toward the middle line of the foot and transfers more of the weight of the body upon the heel. In this way I presume the formation of pes valgus later on is avoided with more certainty. Where, however, the astragalus is left, the correct relation of the axis of the leg must be strictly observed. It is good to support the thigh and calf during the wound dressing, and to advise the person who holds the foot to fix it more by tender manipulation and slight extension than to contribute anything to raising the limb.

After the wounds are healed, which can be achieved usually under a few dressings within, let us say, from six to eight weeks (in some of our cases it was four weeks; in one, the most extensive, the wound is not entirely healed after almost five months), the patient gets a light dressing of pasteboard and starch bandages, or silicate, with quite

thin wooden splints interposed. This dressing goes upward to the middle third of the thigh, and reaches down to the toes, keeping the knee slightly bent. It is split anteriorly, and can be removed and reapplied by means of straps and buckles. I should advise cutting out the region of the heel to such an extent that, for reasons mentioned above, the foot can be slightly pushed backward within the dressing. I extend this dressing above the knee in order to avoid rotation of the leg within the dressing.

Now comes a very important stage of the after-treatment, during which, by means of active and passive movements, electricity, and bathing, the muscular action is stimulated. For this purpose the dressing is often removed and exercise done while the patient is in the lying posture, the limb being raised as much as possible. By and by the child is made to push away a hand, which offers a slight resistance. In this way the young parts are accustomed to pressure, and after some weeks they will be so far advanced that, with the dressing, which must fit very accurately, and allow only of a slight weight being thrown upon the foot, they commence to walk. The parents must be inspired with the importance of devoting all their attention to these exercises. After several more weeks (in four of my cases in about two months after the operation) the patient gets a good-fitting double splint, which is inserted in a strong laced shoe, allows of a movement of about twenty degrees in the region of the ankle joint, and reaches as high as the condyles of the tibia. Here it ends in two side-pieces, which form the upper part of a pretty strong leather cylinder. The latter must be adapted very well to the upper half of the leg as far down as the lower edge of the calf. If the patient has sufficient means, it is good to furnish every lateral splint with a mechanism by which the distance between the condyles and the sole can be increased. This can be used very well to correct abnormal pronation or supination. To improve an abnormal dislocation of the foot forward, pass an elastic ribbon across the lateral steel splints, which presses slightly against the posterior surface of the lower end of the tibia and fibula. These apparatuses will probably have to be worn for years. So far, I have not deemed it advisable to remove the splint in any one of the children, though in one the operation was done almost two years ago. Four of these children run about all day, and one would hardly suppose that they had undergone such extensive operations. I will pass around with every one of the patients a schematic sketch illustrating the extent of the operation and the principal seat of the disease; also the specimens, so far as I deemed it worth while to preserve them.

CASE I.—A boy, now three years and nine months old, began to suffer when nine months of age. He came under my care, when not quite two years old, with serofulous disease of the ankle joint from osteitis of the lower end of the diaphysis of the tibia. Total excision, including the astragalus, was performed on the 28th of April, 1882. There was an extensive serofulous cavity in the lower end of the tibia, which had to be removed. The scar above the new-formed tibia is now 10 cm. long. The amount of bone removed was less, but certainly the operation was very extensive. I saw the patient for about ten days, after which time I put him under the care of my friend Dr. A. Buech-

ler, on account of my going to Europe. The wounds healed in two months. The after-treatment was of the kind described. There was very satisfactory new formation of the lower end of the tibia and fibula, and the malleoli were well developed. The astragalus was apparently replaced by a fat, meniscus-like body. There is slight pes valgus, for which the inner side of the sole has to be raised. The functional result is very good. The shortening at present is about 2 cm.

CASE II.—A boy nine years old came under my care four years ago, with a fistula above the malleolus internus, leading to a scrofulous bone cavity in the lower part of the diaphysis, which was scraped out and healed after a transient attack of inflammation in the ankle joint. He was apparently quite well, without complaining about anything, for about a year and a half, when slight fungoid swelling of the joint showed itself. Being absent from New York, I did not see him until five months later, when the swelling had much increased, abscess had formed, and the limb was quite useless. In October, 1882, I performed total excision of the ankle joint, including the astragalus. This was followed by speedy recovery. Very little new formation of bone took place, and there is some abnormal lateral mobility, with considerable shortening—about 4 cm. The femur of the affected side is also shorter than the other by 1.5 cm. The functional result is good. The boy runs about all day, wearing a high-heeled shoe and a double steel splint. The specimen shows very beautifully the progress of the disease from its original seat through the bone substance of the epiphysis to the astragalus, which shows the most destruction at a point opposite the canal which leads through the epiphysis of the tibia.

CASE III.—A boy nine years old had trouble with his right ankle joint from his second year—often repeated inflammations, later on several abscesses, transient apparent recoveries, with some pain and impaired use of the limb remaining. He came under my care September 30, 1883, with an abscess behind the internal malleolus, which was opened. Caries of the joint was ascertained, for which excision was done on the 9th of October. From the astragalus only the articular part was removed, by means of a broad, sharp chisel. Six weeks after the operation the wounds were completely healed. On the 2d of December the shortening was about 3 cm. There is little new formation of bone, and there is slight lateral mobility. The malleoli are narrow, and the axis of the leg falls a little behind its normal termination in the astragalus. The patient walks safely with and without a brace. The excised portion of the tibia shows very deep irregular depressions, some of which at the line of the operation were filled with organized tissue, while others presented a bare, carious surface.

CASE IV.—A girl, six years of age, for three years had slight limping, and now and then pain, but the foot was always used until one week previous to my seeing her, when she presented thickening of the lower end of the tibia and inflammation of the ankle joint. September 1, 1883, I performed complete excision, including the astragalus. There is excellent new formation of bone, and the functional results are good. One interesting point was that seven weeks after the operation, when the patient had not yet walked, a shortening was made out of 1.75 cm. Three weeks later the shortening was made out to be 3 cm. Perhaps it would have been better to delay the walking exercises. The tibia is now 1.5 cm. shorter than that of the opposite side. The new joint is quite firm and reliable, in spite of slight forward displacement of the foot. The principal element of the disease was a supra-epiphyseal, scrofulous osteitis in the tibia.

CASE V.—A boy, three years old, commenced to suffer when nine months old. There was extensive scrofulous osteitis of the calcaneum and the lower end of the tibia, involving the inter-

posed joints and bones. *Evidement* of the os calcis, with complete excision of the ankle joint, including the whole astragalus, was performed. In the os calcis and tibia scrofulous sequestra were found, which you see here. The patient is still under treatment, because repeatedly the granulations have shown a fungoid character and had to be scraped out. The patient commences now to walk with his starch dressing. I expect a good ultimate result, because a good new formation of bone is going on. The patient's mother died of consumption, and his father is said to be consumptive. I shall present the boy a second time when he is able to walk.

CASE VI.—*Excision for Gunshot Injury.*—A young gentleman, eighteen years of age, tall and slender, of a healthy family, was shot by one of his friends, who was walking behind him, while the muzzle of his gun was at a short distance from the patient's heel. The charge was of small bird-shot. The contents of the gun entered the space between the posterior medial edge of the tibia and the tendo Achillis, about two to three centimetres above the internal malleolus, and passed outward and forward, completely shattering the lower end of the fibula. The tibia was also broken into numerous fragments, the tendons of the long flexors were completely torn, and the tendo Achillis was partly carried away, while the tendon of the tibialis posticus was preserved. The posterior tibial nerve and artery were likewise not torn. They were lying imbedded in their bloody-infiltrated sheath, within which a slight pulsation could be detected. I saw the patient about twenty-four hours after the injury, when several pieces of bone had been removed from the fibula. In spite of the extent of the injury, conservative treatment was tried by excision. Fully 10 cm. of the tibia were removed. A large rent extended from the point of injury down to the joint, within the lower end of the tibia. The operation was done in Pine Hill, Ulster County, in August, 1883, and the after-treatment for the first ten days was conducted by Dr. Laur, of this city. Then the patient was brought to New York, and I took charge of him. Extensive necrosis of the soft parts, and to some extent of the periosteum, occurred, so that open antiseptic treatment with through-drainage was resorted to. Complete cicatrization took place in five months. From that time exercise, massage, and electricity were used. The patient is now able to walk, wearing a double splint with a mechanism for extension which takes part of its support on the thigh. He has lately been able to walk from one to two miles, but his foot is still weak and he uses a cane. The present shortening is fully 5 cm. He wears a shoe with a high heel and sole. The new joint is about 2 to 3 cm. above the normal situation, at the point where the periosteum was most extensively torn. Muscular action is still very weak, and there is profuse perspiration about the foot all the time. I hope that after about a year's time the patient will offer a very fair result.

A NEW METHOD OF TREATING LARGE BONE CAVITIES

IN THE LOWER END OF THE FEMUR IN ADULTS.*

By F. LANGE, M.D.

THOUGH in young persons, as a rule, no considerable difficulty is experienced in healing large bone cavities, I have repeatedly found in adults, after extensive operations on the lower part of the diaphysis of the femur, a very obstinate resistance to complete recovery. These large cavities are sometimes not filled up with permanent tissue,

* Read before the New York Surgical Society, February 26, 1884.

Fistulæ remain, which perhaps, after a longer time of careful treatment, show a tendency to heal; but, after some exertion, or traumatism, or constitutional disturbance, they are apt to open again, with renewed suppuration, and occasionally, after long years of more or less suppuration and attacks of inflammation, amyloid degeneration with its fatal consequences occurs. In looking carefully over hospital records one hardly ever fails to find cases recorded of one or the other of these varieties, the majority of the patients probably at last staying away from hospitals, having, as well as their doctors, become tired of medical treatment. In the three cases which I intend to present I have endeavored, by means of a plastic operation, to entirely obliterate the bone cavity. The operation consisted, with slight modifications, in forming an anterior flap from the soft parts covering the lower end of the femur, which has its base either corresponding with the articular line or laterally. Ankylosis existing in a straight position, the patella was excised and the whole anterior wall of the bone cavity was removed. Finally, an oblique section was made, severing the anterior third of the condyles and descending toward the bottom of the bone cavity. In this way the abruptness of its lower edge is replaced by a smooth, oblique plane. The whole bone cavity must be most thoroughly scraped out and disinfected. I recommend the use of a spray of a disinfectant solution forcibly directed against the bone surface. There is nothing that so thoroughly cleanses the surface as a spray employed in this manner. Then the dorsal flap, whose length must correspond to the extent of the cavity, is depressed toward the bottom of the cavity and eventually fastened by a nail or needle. No sutures are applied. Of course, raw surfaces remain above the edges of the flap, which are left to heal by granulation. It is remarkable how the great difference of *niveau* existing in the beginning disappears in the course of months. After a time the flap is again raised. Apparently a new formation of tissue, probably of bony nature, takes place below it. I was led to adopt this plan by a similar method practiced on the head of the tibia, and recommended by my friend Dr. Neuber. So far as I know, no similar operation has been performed on the lower end of the femur. From this very schematic sketch you can appreciate the condition of the parts before and after the operation.

The three cases to which I have referred are very interesting; they occurred in women of from thirty-eight to forty-six years of age. All of them had a serious osteitis of the lower end of the femur above the epiphyseal junction some twenty-five to thirty-five years ago. None of them underwent any operation at that period, at least no operation upon the bone. In two, small particles of bone came away spontaneously, and that, in one of them, more than twenty years after the first attack. All had long intervals of fifteen and more years of health, with a comparatively useful limb, until, in one case from constitutional disturbance after childbirth, and in the two other cases from traumatic causes, renewed inflammation took place at the original point of lesion. In all of these, large cavities existed in the lower end of the diaphysis, the classical seat of osteomyelitis in young persons. In neither case did these cavities con-

tain any dead bone, but here and there broken-down granulations, so that pus lacunæ were formed. Toward the periphery small spicula of bone were found scattered between the granulations; but all the cancellar tissue was softened, rarefied, and pervaded by granulations and small abscesses. The cortical substance was, to some extent, implicated also. The sharp spoon, with but little force, forms a cavity which is extended beyond the limits of the healthy bone. Finally it is arrested by a hard, sclerotic shell. The epiphysis in all of these cases was in a state of advanced fatty degeneration and rarefaction, but not pervaded by granulations.

In the upward direction, in each instance, there was no distinct boundary toward the medullary canal, at least no bony diaphragm, which is the rule in those standard bone abscesses which, I think, clinically and pathologically require a different conception from those just described. Not long ago I presented to this society a case of bone abscess in the lower half of the femur. The patient was about twenty-seven years of age, and his history was very similar to those of the patients now under consideration. In his case, however, the bone abscess was narrow, long, consisting of many small, lengthy pus lacunæ, and reaching almost as far as the middle of the femur. The cortical substance was enormously thickened, and a very small particle of dead bone was found within the cavity. The nature of this case was, I think, exactly the same as in the present ones, but the process of new formation of bone was much more active, while the granulating process within the medullary spaces was not so active as to lead to the formation of a large cavity at the expense of pre-existing bone tissue. Essentially, however, the contents and walls of this cavity were of the same nature. It seems to me that these cases must be kept apart from those bone abscesses which, within a smooth sclerotic bone cavity, covered by a rather smooth, pyrogenic membrane, contain a peculiar creamy pus.

Let me mention that all these patients were born in regions where acute osteomyelitis is more frequently observed; one of them in Switzerland, the two others in the low-lands of northern Germany.

CASE I.—Mrs. P., forty years of age, born in Switzerland, of a healthy family, had severe typhoid fever in her twelfth year, after which she was reduced for a long time to a state of considerable physical feebleness. During this period, and several months after the first-mentioned disease, she had a fall of about four to five feet, striking on her feet. After that she had pain in her left knee for a short time, which very soon returned with great severity during her day's work. A severe inflammation of the bone followed, and was accompanied for a long time with pain and fever. After continued application of poultices, an abscess broke above the knee, on the medial and lateral aspect of the femur. A great deal of pus escaped, and subsequently several small particles of bone came out. After a duration of about half a year, the process now healed, the limb became useful and remained so, except on account of what the patient called "slight rheumatic" pains. There was no ankylosis. She married in her nineteenth year, and has had eight normal labors. In May, 1880, she fell from a staircase and received a severe blow on the left knee, which caused much pain and swelling. About six weeks later I saw her in consultation with Dr. Moeller. At that time there existed an extensive supuration in and about the knee, which required a good many

incisions. It was found that the patella was broken, and that a kind of diaphragm passed from the seat of fracture near the upper edge of the patella toward the condyles, thus separating the upper recesses into two cavities, both of which were filled with pus. In about four or five months the patient was again able to walk with a stiff limb, fistulæ remaining at the anterior aspect somewhat above, and another at the outer aspect corresponding to the lower edge of the external condyle. The knee was in supereextension, and an abnormal lateral mobility remaining for a long time. The sinns led toward the joint in a downward direction. The lower end of the femur was thickened, and the soft parts were tense and immovable, but not particularly painful on pressure. The history of the following two years, during which time the patient was not treated by me, is, in short, this: The sinns showed a tendency to heal, but then, with increasing pain and swelling, and absolute powerlessness for weeks, ample discharge occurred, after which the limb returned to a more normal condition. At last the patient consented to a renewed operation, which I had proposed years before, assuming that the real seat of the suppuration must be in the lower end of the femur. I performed the operation on the 27th of April last year in a way similar to that which I have described. You see here the fractured patella, which does not offer any feature of peculiar interest. A large cavity occupied the lower end of the thickened femur. It was laid open freely. A fistulous tract led through the obliterated joint between the condyles to the posterior surface of the femur. The fistula on the outer aspect communicated with that. The bone here was also softened and in a state of rarefaction. A good deal of it was gouged away. The soft parts on the anterior aspect were not so intimately depressed into the anterior deep bone cavity, nor was that feasible, because in this case I had not yet made the horizontal section of the anterior portion of the condyles. The lower edge of the cavity, therefore, was too abrupt. Gradually complete recovery took place, not, however, without a slight attack of retention about three months after the operation. Still the soft parts, by the process of cicatrization, seem to have been gradually drawn into the cavity. The limb is completely ankylosed, but reliable and useful. Cicatrization was completed in from four to five months after the operation.

CASE II.—Mrs. B., forty-six years of age, of a healthy family, had, in her seventeenth year, a severe inflammation above the right knee, preceded by rigor. The left knee was also affected in the beginning, but improved spontaneously. After two weeks of severe suffering, an ample discharge of pus occurred above the internal condyle. The wound closed itself after several weeks, broke out again after the first trials to walk, and then healed completely, and after a time the limb became useful. Flexion was somewhat impaired, and remained so.

In 1870 she suffered from a lung trouble, which was thought to be consumption. During this time she again had sudden pain in the limb previously affected, with rigors, redness, and swelling. After several weeks an abscess broke at about the old spot. No pieces of bone were discharged. Four months later the patient was able to walk again, but a fistula remained, mobility grew less and less, and finally the leg became quite stiff. In January, 1883, she fell down stairs, and, not being able to take the necessary care of herself, she soon commenced to suffer again from severe pain above the knee joint. On March 31st I was called in consultation with Dr. Balser, and opened, by two long incisions, a large, apparently periarticular abscess on the inner aspect of the knee. Sinuses remained, with repeated attacks of retention, apparently due to an ositic process within the bone. In September the radical operation was done in the manner originally described. A large opening was found to exist on the anterior aspect of the femoral bone, tightly covered

by the quadriceps femoris and upper edge of the patella. The cavity itself reached as far down as the epiphysis, which latter was in a state of advanced fatty degeneration.

Complete recovery took place in about three months. There is almost complete ankylosis. The patient is wearing a brace, in order to promote stiffening. The limb is becoming useful and stronger, and she is able to walk a few blocks, and improves every week.

CASE III.—Mrs. T., thirty-three years of age, had an acute osteitis in her thirteenth year, for which she was under medical treatment for seven months. An abscess broke and a yellowish, "mostly serous" fluid was discharged. For the whole year subsequent to that the leg was stiff and flexed, and she was obliged to use crutches. But under the use of salt-water baths it became almost normal, flexible, and useful. Fourteen years later the patient married, and four years after that she was delivered for the second time. That was in 1881. She had a protracted puerperium, with fever, and became much reduced in strength. Two months after that her thigh became inflamed; she was in bed for nine weeks, and an abscess broke above the inner margin of the patella, but more of a serous, yellowish pus was discharged. That healed, but, after a short time and a renewed inflammation, it again broke. A fistula remained; the knee became quite stiff, but gradually could be used to some extent. In May, 1883, a small piece of bone was discharged, and in June, after a renewed attack of severe inflammation, still another. In September I saw the patient and proposed an operation, which was performed at Bellevue Hospital on the 3d of September. I confined myself to laying bare the fistulous opening which led into the bone on its anterior external aspect, corresponding about to the upper edge of the patella. The tendon of the quadriceps had to be divided. The opening was enlarged and a large cavity scraped out, drained, and treated with the permanent antiseptic dressing. Everything went along nicely for about two months, when renewed retention and inflammation occurred. I then decided to do the radical plastic operation. This was done by my brother, on the 28th of November, under my direction. The defect of bone in this case was, perhaps, the largest of all. The epiphysis was so much fattened and its cancellar tissue so rarefied that it broke under the chisel and was made smooth by means of a knife. The lower part of the diaphysis, the seat of the cavity, was very much thickened, but only a comparatively thin shell of bone remained, into which the large dorsal flap was depressed. Its point was fastened by a steel needle driven into the bone. Recovery took place in about ten weeks, and within about five days the patient has commenced to walk with a brace in order to keep the limb entirely stiff and not to allow of that slight spring-like mobility which exists in this case as well as in that just presented.

The patella, as you see, shows on its posterior surface ositic thickening and a carious surface just about that point where for a long time it has been exposed to the influence of the inflammatory products.

It was peculiar to all of these cases that the adit to the bone cavity was on the anterior aspect, corresponding about to the insertion of the quadriceps femoris.

DENTAL HYGIENE AT SCHOOL.—According to M. Galippe, dental caries is frequent in boys and girls preparing for examination, and may be ascribed to the excessive efflux of blood to the head. Others suppose that the brain makes use of the phosphates which ought to be employed in the formation and growth of the teeth. M. Harlan is of opinion that dental caries is most frequent in young people who work hard, and are very successful in their examinations.—*British Medical Journal*.

Correspondence.

LETTER FROM ST. LOUIS.

An Enormous Ovarian Tumor.—A Suit against a Medical Society.—The St. Louis Protestant Hospital.—College Commencements.

St. Louis, March 3, 1884.

I was told a few days ago, by a prominent physician of this city, of a case which he had seen, by the courtesy of another physician, of what was believed to be the largest ovarian tumor on record. The patient is a mulatto woman between forty and fifty years of age, rather small and slight apart from the tumor. The measurement around the tumor is seventy-two inches. The woman, with the tumor, weighs 306 pounds, and it is estimated that without it she would not weigh over 100 pounds. It is thought that the tumor contains about twenty-five gallons

of fluid. As she sits in her chair, the tumor projects forward beyond her knees, and the muscles of the thighs are atrophied from the pressure. The breasts lie loosely upon the upper part of the tumor. The legs are somewhat œdematous. The woman has a good appetite, is quite comfortable except from the weight and pressure of the tumor, and seems to be quite proud of the tumor, as she has been so often told that it is the largest one known. She states that some years ago she was tapped, and only a small quantity of fluid was removed, which, when it cooled, became firm as stiff jelly. She states further that the tumor is still increasing at the rate of ten or twelve pounds a month. I am told that probably an attempt will be made to remove the woman from the tumor.

Some time ago I mentioned that a practitioner of this city had been expelled from the St. Louis Medical Society, and that he had thereupon entered suit against the committee who had formulated the charges, the sustaining of certain of which had led to his expulsion. He claimed damages to the amount of \$10,000 on each of five counts, making a total of \$50,000. When the case came up, however, he withdrew the suit as to three counts which had been proved before the society's Committee on Ethics, and maintained his suit only on the two counts which that committee had held to be not proved, although they were convinced of the truth of them. One of these counts was a charge that the said physician was an abortionist. He professed to be greatly aggrieved and injured thereby. Within the past fortnight he has been found guilty in one of the courts of performing a criminal abortion, and has since withdrawn his suit against the committee.

Monday morning, at a meeting of the Evangelical Alliance, an association of the Protestant clergymen of the city, action was taken indorsing the movement to establish on a firm basis a Protestant hospital in this city. Up to this time the hospitals of the city have been chiefly under the charge of various Roman Catholic sisterhoods. Of course, I do not here refer to the public institutions conducted by the Health Department. While these Catholic orders have a number of handsome buildings, well equipped and efficiently administered, there have been only three under Protestant auspices—viz., St. Luke's Hospital, which is carried on by the Episcopal churches of the city, and the Good Samaritan Hospital, supported chiefly by the German Lutheran congregations. Besides these, I should also mention a small institution, the Children's Hospital. The professional staffs of the Good Samaritan and Children's Hospitals are composed of homœopathic practitioners, although others are not excluded from treating patients in the former institution. It is believed that the indorsement given to the St. Louis Protestant Hospital by the Alliance and the recommendation of its support by the churches will enable its officers to make such an appeal to the philanthropic people of the city as will give the institution a permanent footing and secure its success. A small work has been carried on for two or three years, which has demonstrated the need for an enlargement of it; and there seems reason to hope now that the opportunity for such enlargement has come.

The commencement exercises of the medical colleges of this city have taken place this week. Tuesday afternoon the Missouri College graduated a class of one hundred and one members, the exercises being held in the Grand Opera House. Tuesday evening the College of Physicians and Surgeons issued diplomas to twenty-six graduates, and Wednesday evening a class of thirty-two were sent out from the St. Louis Medical College. Flowers and music added their charm to the various exercises, and the young men went forth to their life-work with bright hopes and eager anticipations. How many of them will realize them?

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MARCH 15, 1884.

THE REGULATION OF MEDICAL PRACTICE IN LOUISIANA.

THE recent annual publication of the Louisiana "Act Relative to the Practice of Medicine and Surgery," a publication required by the terms of the act, calls attention anew to its main provisions. If the profession of the State of New York are to recommend to the next Legislature a bill that shall not only have some chance of becoming a law, but also deserve to acquire the binding force of law, it behooves them to study the provisions and, so far as practicable, the working of laws passed for like purposes by other States.

The Louisiana law does not differ radically from several other State medical laws. No State examination is required, only the possession of a diploma from some "respectable" medical college, and the State Board of Health is made the judge of what constitutes the respectability of a medical college. We can not but regard this as an error. We are aware that several State boards have succeeded in giving a tolerably satisfactory definition of the "good standing" of medical colleges, and have used the powers conferred upon them in this direction with discretion and substantial fairness, and we do not doubt that the Louisiana board will pursue a like course so long as it is constituted as it is at present. In making laws, however, it should be borne in mind that they need shaping so as to leave as little as possible to the discretion of the administrative power. State boards of health are as yet a new thing in this country, and to a great extent they are made up of men whose devotion to sanitation and to the public welfare in general is untinctured by any disturbing spirit. How long this will continue to be the case in any State, it is impossible to say; already some of the State boards have given indications that party politics, to say nothing of less creditable influences, can not be said to be wholly without effect upon their acts. It should be mentioned that the Louisiana act restricts the action of the State board in one respect, in that it forbids any discrimination between colleges founded upon the system of therapeutics taught in them.

The Louisiana law has been in operation only a little more than a year, so that, as it allows of the registration of practitioners of five years' standing who are destitute of a diploma, but little progress should be expected to have been made by it in elevating the character of the profession. It is not a matter to excite surprise, therefore, that the same number of the official newspaper which publishes the text of the law, and the list of practitioners registered under its provisions, should contain also the advertisement of a most arrant quack, who announces himself as "a regular graduate." A partial exemption is extended to practitioners of ten years' standing who

have a diploma—they must make affidavit that they have received a diploma from a regularly incorporated medical college in America or Europe, of reputable standing, but such diploma need not be "vised" by the State Board of Health.

The formalities of the registration are simple and inexpensive. The diplomas of those who fall within the full operation of the law must be indorsed by the board, the original affidavits made by them are retained by the board, and copies, which are to be had for a trifling fee, are legal evidence of qualification in any court of law. It seems to us a wise provision of the law which requires its official publication annually in a newspaper, together with a certified list of the practitioners registered under it.

ANIMAL VACCINATION IN LYONS.

THE public vaccination service of the city of Lyons seems to have fallen somewhat into discredit with the profession of the place, if we may judge from an article published in a recent issue of "Lyon médical." The writer of the article, Dr. Chambard, accounts for this fact in some measure by stating that the efforts of the officials in charge were passed upon prematurely, before they had mastered the technics of animal vaccination. He maintains, indeed, that the results were never so bad as the profession represented them to be—a statement that we can readily believe—and goes on to show that they are now all that could reasonably be expected, that is to say, a success of ninety-six per cent. in primary vaccinations, and of fifty per cent. in revaccinations, in the use of stored vaccine.

Thus far, there is nothing remarkable about the story, except that the percentage of successes attained is not so high as it ought to be, although it must be conceded to be fair. But our curiosity is excited by the recital of the measures to the adoption of which the improvement is imputed, consisting mainly in a novel method of storing what the writer is pleased to consider vaccine. It seems that it is prepared in the form of an electuary (*electuaire vaccinal*), made up of three active (?) ingredients: lymph from the cells of the pock, the crust which surmounts it, and a magma obtained by subjecting the floor of the pock to a process of *raclage*. The crust is reduced to a powder with sugar (to aid in its comminution), and to the moist powder thus formed are added the pulp obtained by scraping the base of the pock, the coagulum from the lymph, and a pinch of gum tragacanth, so as to make a thick mucilage. This mucilage is brought to the proper consistence by the gradual addition of a mixture of equal parts of distilled water and neutral glycerin. Thus concocted, the electuary is kept under a bell-glass, and is said to retain its virtues practically unimpaired for about two weeks. It is sent out stored between plates of glass.

Concerning the only other measure to which the increased success is credited—the adoption of the method of insertion by scarification, instead of that by subcutaneous injection—we have nothing more to say than that it was a step in the right direction. In regard to the electuary, however, we must express our decided conviction that it is not to be commended. In common with most French operators, the gentlemen in

charge of the Lyonnese establishment take vaccine from the calf on the fifth day after its inoculation. At that period the crust, besides being open to the objections that always apply to crusts, is simply a traumatic product; it is not the "concrete vesicle" at all, but the dried blood and serum that flowed out at the time the vaccination was done, together, perhaps, with a re-enforcement to its applied surface in the shape of fluid that may subsequently have exuded as the result of injury to the pock, which fluid is manifestly unfit for inoculation.

As to the mass obtained by scraping the floor of the lesion, it is almost necessarily contaminated with shreds of inflamed tissue, and in many instances can scarcely fail to contain the necrosed tips of the papillæ of the skin. We can not concede that it is wise to rely on any supposed antiseptic power of the glycerin to guard against the possible effects of inoculating with such materials. Vaccinal mixtures are deservedly in disrepute in this country; we are satisfied with the simple lymph. It is easy to understand the improved results attained by the Lyonnese gentlemen, imputing it merely to their increased experience; we are persuaded that their results would be quite as good, if not better, were they to discard their elaborate electrolytic, and use only dried lymph.

THE NAVAL MEDICAL SOCIETY.

On several occasions we have expressed our satisfaction at the quality of the work done at the meetings of the Naval Medical Society. The last number of the "Proceedings" gives gratifying evidence that this work is kept up to the high standard with which the society set out. Dr. Albert L. Gihon contributes two important articles—one entitled "Thirty Years of Sanitary Progress in the Navy; its Present Needs," and the other, "A Case of Pyæmia Supervening upon Hæmorrhoids in a Syphilitic." The first-named paper gives ample illustration of the improvement which has been effected in marine sanitation during the period referred to, as well as of the growing appreciation of the importance of the matter by the line officers and the bureau officials. It is followed by a paper much to the same purpose, by Dr. John M. Browne, which is a tribute to the achievements of a British naval sanitarian of a by-gone generation, Dr. Thomas Trotter, "Physician to the Fleet." So vividly has Dr. Browne portrayed the work of the old pioneer that, although the paper avowedly draws much of its substance from the publications of its subject, it reads quite like a personal reminiscence—so much so that the reader is constantly surprised to find himself under the delusion that Dr. Browne and Dr. Trotter were at least contemporaries.

The contents are completed by a short article, by Dr. J. H. Kidder, on the "Bacillus Tuberculosis." Short as it is, and lacking the advantage of previous preparation, being apparently a report of extemporaneous remarks, written out subsequently, it is nothing less than a gem. On the mere occasion of showing a specimen of the bacillus, Dr. Kidder managed to give a succinct but very sufficient historical sketch of the fungus theory of tuberculosis, an appreciative review of the facts which led up to it, and a remarkably clear summary of the considerations

which should govern our judgment of the theory—all in the course of remarks which take up but three octavo pages of print. If such work as this were oftener done at society meetings, instead of the labored papers and pointless, rambling discussions that are so apt to take up the time of a meeting, the advance of medicine would be immeasurably promoted.

THE NEED OF AN AMBULANCE SERVICE IN PARIS.

It is but a few years since Dr. Henri Nachtel, of Paris, made us acquainted with the beneficent operation of the Night Medical Service of that city. Without loss of time, New York took the hint, and a night service was established. During his stay here Dr. Nachtel was impressed with the usefulness of the ambulance service connected with our hospitals, and, on his return to Paris, took pains to set forth its advantages to the medical profession in that city, the result of which was that a body representing the profession formally recommended to the municipal authorities the adoption of a similar system. Nothing has ever come of the recommendation, however, and Paris is still without any adequate means of affording relief to the victims of street accidents and the like with the promptness that is often an essential element in their treatment.

The need of such a service was lately exemplified in a most pointed way, in the case of a woman who, having been severely injured in the head, was compelled to lie in the street for two hours, and finally had to be taken to an apothecary's shop, and from there to *la Pitié*. This incident having found its way into the newspapers, the medical profession, as usual, came in for a copious amount of criticism, the doctors being accused of cupidity, negligence, cruelty, and various other unlovely qualities, the idea being, apparently, that a medical man is supposed to divine when and where his services are needed, and to present himself instantly and without stopping to inquire as to the chance of recompense. It is certainly unworthy of a great municipality to leave the care of injured and disabled persons to the voluntary services of the few men composing the medical profession, and it is not surprising that one of our Paris contemporaries takes the incident alluded to as a text from which to argue the pressing need of an ambulance service in that city.

MINOR PARAGRAPHS.

THE COUNTY SOCIETY'S "COLLECTIVE INVESTIGATION."

The March meeting of the Medical Society of the County of New York, to be held on the 24th inst., is likely to bring out an important discussion on the subject of intestinal obstruction, unless the time that can be devoted to it turns out to be too limited. There is some danger that this may be the case, inasmuch as the discussion is not to begin until after the paper of the evening has been read. The president having touched upon the matter of the "collective investigation of disease" in his inaugural address, the committee to which the address was referred have issued circulars to the members of the society, asking them to attend the meeting and take part in the discussion, and to send to the chairman of the committee, Dr. David Webster, before the 15th inst., written answers to the following

questions: 1. "How many cases of intestinal obstruction have come under your observation, and what peculiar symptoms were manifested in each case?" 2. "Have you ever performed an operation for the relief of intestinal obstruction due to peritoneal adhesions, and, if so, what was the result in each case?" 3. "Have you treated any cases of intestinal constriction, partial or complete, where the so-called pathognomonic symptoms, such as stercoraceous vomiting and obstinate constipation, were absent?"

NEWS ITEMS, ETC.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 11, 1884:

DISEASES.	Week ending Mar. 4.		Week ending Mar. 11.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	3	0
Typhoid Fever.....	10	7	11	6
Scarlet Fever.....	78	19	69	8
Cerebro-spinal meningitis.....	3	3	5	7
Measles.....	41	4	44	5
Diphtheria.....	35	21	44	21

POISONING BY ILLUMINATING GAS has been stated, on the strength of clinical observation, to be more than ordinarily pronounced when produced by the so-called "water gas." Nevertheless, Professor Chandler is reported to have testified before the State Board of Health last Wednesday that it was not more deadly in its effects than coal gas.

THE ACADEMY OF MEDICINE.—At the next regular meeting, on Thursday evening of next week, Dr. Leonard Weber will read a paper on "Locomotor Ataxia and Syphilis."

AN ARTICLE ON INTRA-UTERINE INJECTIONS has been received by the editor of this journal, but it is destitute of a title, and there is nothing to show its authorship. If the author will supply these deficiencies, we shall be happy to publish the paper.

HOWARD UNIVERSITY.—The annual commencement exercises of the medical department were held on Monday evening, the 10th inst., and the degree of doctor in medicine was conferred on a class of twenty-one gentlemen and ladies.

THE ALBANY MEDICAL COLLEGE held its fifty-second annual commencement on Wednesday evening, the 5th inst., the graduating class numbering forty-one. The meeting of the Alumni Association, held the same day, was attended by one hundred and twenty-two members. The following-named gentlemen were elected officers of the association for the ensuing year: President, Dr. Horace T. Hanks, of New York; Vice-Presidents, Dr. George M. Teeple, of Bridgeport, Conn., Dr. Edwin Barnes, of Pleasant Plains, N. Y., Dr. A. B. Burger, of Mechanicville, N. Y., Dr. E. S. Allbee, of Bellows Falls, Vt., and Dr. W. A. Hall, of Fulton, N. Y.; Secretary, Dr. Willis G. Tucker, of Albany; Treasurer, Dr. G. L. Ullman, of Albany; Historian, Dr. J. B. Stonehouse, of Albany; Executive Committee, Dr. Albert Van Derveer, Dr. Lorenzo Hale, Dr. C. B. Herrick, and Dr. Maurice J. Lewi, all of Albany.

THE BALTIMORE MEDICAL COLLEGE held its annual commencement on Thursday, the 6th inst., the graduating class numbering thirteen.

THE UNIVERSITY OF THE CITY OF NEW YORK.—The forty-third annual commencement of the medical department was held at the Academy of Music on Tuesday evening, the 11th inst. The graduating class numbered one hundred and sixty-

four gentlemen. Prizes were awarded to A. J. Meuer, C. J. Kane, and W. E. Kissam, of New York, C. A. Rhodes, of New Jersey, G. A. Thomson, of Indiana, and R. C. Eddy, of Syria. The honor men were as follows: C. A. Rhodes, G. A. Thomson, D. S. Dougherty, R. C. Eddy, W. T. Cleaveland, W. C. Eidenmüller, J. M. Stanley, J. E. Giles, E. M. Parker, W. F. Crandall, H. S. Stearns, J. W. Van Deusen, J. B. Bogart, F. K. Perkins, L. Baumann, W. S. Terrey, J. D. Jones, and J. W. Ellis.

THE ARKANSAS STATE UNIVERSITY.—The annual commencement of the medical department was held on Monday, the 3d inst., and the degree of doctor in medicine was conferred on a class of thirteen.

THE NEW YORK MEDICAL UNION is the new name of the society formerly known as the East River Medical Association, the change having been determined upon, we understand, on account of the society's having outgrown its original territorial limits.

THE ITALIAN MEDICAL ASSOCIATION.—It is announced that the meeting which should have been held this year has been postponed to next year, on account of the exposition to be held in Turin.

THE GERMAN SURGICAL CONGRESS.—It is announced that the thirteenth congress of the Deutsche Gesellschaft für Chirurgie will be held in Berlin from the 16th to the 19th of April. So far as the programme has been published, it includes the following papers: "On the Physiological Connection between the Spleen and the Thyroid Gland," and "On the Treatment of the Paraplegia of Spondylitis," by Dr. Zesas, of Zürich; "On Ferment-Intoxication occasioned by a Blood-Cyst," by Dr. Cramer, of Wiesbaden; and "On Massage," by Dr. Zabludowsky, of Berlin.

A THREAT TO ROB A GRAVE is said by the Philadelphia newspapers to have been made lately by a physician of that city, the case being that of a lad twelve years of age, who died the subject of congenital cyanosis. The rumor probably has no more foundation than an expression of regret on the doctor's part that the parents would not consent to a post-mortem examination.

DR. ALFRED HOSMER, OF WATERTOWN, MASS., is reported to have resigned the position of medical examiner for the county of Middlesex.

THE LOSS OF AN OLD MEDICAL BOOK.—We learn from our London contemporaries that a book entitled "Speculum Matricis," written by Woolveridge, and published in Dublin in 1670, is supposed to be the earliest original treatise on midwifery published in the English language, and that until within the past two years the only copy of the book known to be in existence was the property of Dr. Fordyce Barker, of New York, who, at the request of the Obstetrical Society of London, undertook to have a copy made of it for the society. He employed a poor Frenchman, named Emile Bourgeaud, to make the copy, but before the work was completed Bourgeaud left this country for Brazil, and has been lost sight of. As he took the book with him, it is lost to the world for the present, but it is hoped that some member of the profession may yet succeed in obtaining a trace of it. It is now stated by Dr. J. H. Aveling that there is a copy of the book in the Radford Library of St. Mary's Hospital, Manchester, England.

THE TRICHINIASIS QUESTION IN FRANCE.—It seems likely now that a system of inspection of American pork by the French themselves will be settled upon, and that, pending the arrangement of the details, the present prohibition will be relaxed.

THE GARFIELD MEMORIAL HOSPITAL.—It is announced that a sum of about \$3,000 is still needed to equip the hospital for the accommodation of thirty patients, that a portion of this amount has been subscribed by a few ladies of Washington, and that an entertainment will be given in that city for the benefit of the hospital on the evening of Easter Monday.

ADULTERATED MUSTARD has been found in the markets by Dr. Edson, one of the inspectors of the Health Department of the City of New York, and the board entertains the suspicion that the mustard in question is injurious; but the manufacturer, having been cited to appear, asserts that such is not the case.

AN APPOINTMENT.—Dr. John H. Nesbitt is reported to have been appointed one of the surgeons to the Police Department.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 2, 1884, to March 8, 1884:*

PERRIN, GLOVER, Lieutenant-Colonel and Surgeon. Medical Director, Department of Dakota. Leave of absence extended twenty days. S. O. 23, Headquarters Division of the Missouri, March 5, 1884.

BILL, J. H., Major and Surgeon. Granted leave of absence for one month. Par. 1, S. O. 20, Headquarters Department of the Platte, March 3, 1884.

BAILY, J. C., Major and Surgeon. Granted leave of absence for one month, to take effect on or about March 1, 1884, with permission to apply to the Adjutant-General of the army, through Division Headquarters, for an extension of three months. S. O. 24, Headquarters Department of Texas, February 26, 1884.

BACHE, DALLAS, Major and Surgeon. Leave of absence extended seven days. Par. 1, S. O. 43, Headquarters Department of the East, March 5, 1884.

FISHER, WALTER W. R., and **POLHEMUS, ADRIAN S.,** First Lieutenants and Assistant Surgeons. Assigned to duty in Department of California.

STEPHENSON, WILLIAM, BORDEN, WILLIAM C., and **CHAPIN, ALONZO R.,** First Lieutenants and Assistant Surgeons. Assigned to duty in Department of the Platte.

ROBERTSON, REUBEN L., and **EDIE, GUY L.,** First Lieutenants and Assistant Surgeons. Assigned to duty in Department of Texas.

CROSBY, WILLIAM D., First Lieutenant and Assistant Surgeon. Assigned to duty in Department of Arizona.

GANDY, CHARLES M., First Lieutenant and Assistant Surgeon. Assigned to duty in Department of the East.

PILCHER, JAMES E., First Lieutenant and Assistant Surgeon. Assigned to duty in Department of Dakota. Par. 4, S. O. 55, A. G. O., March 6, 1884.

STEPHENSON, WILLIAM, First Lieutenant and Assistant Surgeon. Ordered to Fort Niobrara, Nebraska, for temporary duty, on completion of which to return to his station, Fort Omaha, Nebraska. Par. 4, S. O. 20, Headquarters Department of the Platte, March 3, 1884.

FISHER, WALTER W. R., First Lieutenant and Assistant Surgeon. Assigned to duty at the Presidio of San Francisco, Cal., from 18th inst.

POLHEMUS, A. S., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Winfield Scott, Cal., from 18th inst. S. O. 23, Par. 1 and 2, Headquarters Department of California, February 21, 1884.

PHILLIPS, JOHN C., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Fort Warren, Mass. Par. 2, S. O. 39, Headquarters Department of the East, February 23, 1884.

BENHAM, R. B., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort A. Lincoln, D. T., and ordered to Fort Sisseton, D. T., for duty. Par. 1, S. O. 22, Headquarters Department of Dakota, February 26, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending March 8, 1884:*

AMES, H. E., Passed Assistant Surgeon. From the Colorado, and ordered to the Greely Relief steamer Bear.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, March 17th:* Medico-Chirurgical Society of German Physicians.

Tuesday, March 18th: New York Academy of Medicine (Section in Theory and Practice of Medicine); New York Obstetrical Society (private); Medical Society of the County of Kings, N. Y.; Ogdensburg (N. Y.) Medical Association.

Wednesday, March 19th: Roman Medical Society (private); Medical Society of the County of Allegany, N. Y.; Newark (N. J.) Academy of Medicine.

Thursday, March 20th: New York Academy of Medicine.

Saturday, March 21st: New York Medical and Surgical Society (private).

OBITUARY NOTES.

OTIS BULLOCK, M. D., of WARREN, R. I.—Dr. Bullock, an old and respected physician, died March 6th, in his seventy-ninth year. He was a native of Sterling, Conn. His father practiced medicine until about eighty years of age, most of the time in Rehoboth, Mass., and died at the age of ninety-two years. Dr. Bullock graduated at Harvard Medical College in 1832, was president of the Rhode Island Medical Society for several years, and was a member of the American Medical Association for twenty-five years. He maintained an untarnished reputation, and was highly respected and beloved both as a physician and as a man.

DR. ALEXANDER WOOD, OF EDINBURGH.—The death is reported of Alexander Wood, M. D., F. R. S. E., F. R. C. P. E., one of the prominent members of the Edinburgh profession. The deceased gentleman was a contributor to various departments of medical literature in the course of a long and honorable career. In this country he was best known as the chief promoter, if not the inventor, of the method of medication by the use of the hypodermic syringe.

Letters to the Editor.

IMBEDDING IN CELLULOID.

To the Editor of the New York Medical Journal:

SIR: Will you or some of your correspondents, who are versed in microscopy, kindly explain the steps of the process of imbedding in celluloid for section-cutting?

Faithfully yours,

A. L. O.

POTTER'S "COMPEND OF MATERIA MEDICA."

SALT LAKE CITY, March 1, 1884.

To the Editor of the New York Medical Journal:

SIR: In your issue of the 23d ult. my "Compend of Materia Medica and Therapeutics" is blamed for an error as to the morphine dose (stated as half a grain), under the therapeutics of cinchona. I beg to call attention to the fact that the prescription is taken from a very recent authority, viz., "Bartholow's

Materia Medica," and has gone through five editions of that book (see last edition, page 183). As my Compend is based on the principal text-books, I am not responsible for this statement, but do plead guilty to remissness in not placing a note of interrogation after it. I pride myself on the correctness of my work, and hence will thank you if you will give publicity to this, as your review may convey the idea that the book is carelessly compiled.

Very truly yours,

S. O. L. POTTER.

Proceedings of Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of March 6, 1884.

R. A. CLEMMANN, M. D., President, in the chair.

CORRECTION OF A MISSTATEMENT.—DR. WILLIAM GOODELL made the following correction: "At the last meeting of this society I made a misstatement with regard to that distinguished ovariotomist, Mr. Tait, which I greatly regret, and which I wish here to correct. I was misled by some remarks made by Dr. Sutton at the last meeting of the American Gynecological Society. These were so reported as to convey to my mind the impression that Billroth was the only European operator who did not refuse any case of ovarian tumor, however unpromising it was, and that Mr. Tait—to borrow Dr. Sutton's language—'does not remove many large tumors, those which weigh from sixty to sixty-five pounds, with extensive adhesions, etc.' In quoting this, by a careless slip of the pen I changed the word 'many' into 'very,' and, in addition, I wholly misapprehended the purport of the sentence. Dr. Sutton has since, in the 'Medical News' of February 23d, explained that he did not mean that Mr. Tait selected his cases, for he was 'not aware that this British ovariotomist refused to remove a tumor because it was large'; but that 'Mr. Tait had the largest line of ovary and tube cases, and the shortest line of big ovarian cysts, of any man I [Dr. Sutton] visited in Europe.' In making this correction here, I wish to repair the injustice which I unwittingly did Mr. Tait before this society."

EXTRA-OVARIAN CYST.—DR. GOODELL then exhibited a specimen with the following history: The lady, aged twenty-eight, the mother of four children, had a miscarriage early in last October. At that time her family physician discovered the tumor. It grew slowly, but gave the lady so much inconvenience from pain and pressure that she was brought to his office late in the following December. It was not large, but was very sensitive, and was diagnosed to be an ovarian tumor. Both ovaries were removed early last February, and the lady recovered promptly. The peculiarities of the cyst were to him unique. The ovary lay to one side of a thick-walled cyst, and at such a distance from it that the cyst could have been removed without injury to the ovary. The latter was, however, extirpated along with the cyst, because it was diseased. Hitherto all parovarian cysts which he had encountered had been thin-walled and had contained a clear fluid. But this one had thick walls and contained a turbid, brown fluid. It started from the left broad ligament, and was adherent to the bladder, omentum, and abdominal wall. Another point of interest was the fact that the right ovary had doubled its size from follicular degeneration, and yet pregnancy had taken place.

Dr. ROBERT P. HAREIS suggested the possible existence of a third ovary as the starting-point of the tumor. He also thought that the presence of a third ovary might explain the persistence

of the menstrual flow in some cases after the operation of double ovariectomy.

COCCYGOdynia.—DR. GOODELL also exhibited a coccyx removed for coccygodynia. The patient had met with a fall down stairs some years previously, and the injury was followed by a vaginal abscess of some kind. She had all the classical symptoms of a very bad coccygodynia, and had fallen into a nervous condition which bordered on insanity. Dr. Goodell had intended merely to sever the nervous attachments of the coccyx by the sweep of a tenotomy knife, but, after the patient had been put under ether, the tip of the bone was found unnaturally movable and giving distinct crepitation. The loose bone was therefore removed, and, as the articulating surfaces were found rough and denuded, the whole coccyx was removed with a bone forceps. Great relief followed this operation.

Although he had seen very many cases of coccygodynia, this was the first case in which he had operated. In a very few traumatic cases he had wished to operate, but had not been permitted to do so. The vast majority of these cases were, in his experience, those of nervous or neuralgic coccyx, and they got well in his hands under rest, massage, electricity, and appropriate constitutional treatment. The great difficulty, in cases of severity, was to decide between the nervous mimicry of the disease and pure traumatic coccygodynia in which positive lesions had been sustained and their effects had not yet passed away—as, for instance, in a sprained or a fractured coccyx, or in a rheumatic, a gouty, or an indamed coccyx. There was yet another difficulty in the way of diagnosis, for sometimes an injury received by an hysterical woman was followed by local nervous phenomena which would last long after the original lesion had been cured. For example, on one occasion he had been so greatly deceived in the diagnosis between traumatic and nervous coccygodynia as to make him very cautious in resorting to the use of the knife. A highly intellectual lady, who spent her leisure in reading metaphysical works, received an injury to her coccyx by the sudden "bucking" of a horse on which she was mounted. She was at that time suffering from nervous prostration, and the blow started up very exacting coccygeal symptoms. Dr. Goodell found retroversion and a prolapse of both ovaries. These dislocations were remedied, and the patient was put under a vigorous constitutional treatment; but she grew no better, and an operation was proposed and agreed to. As soon as the day and the hour were decided upon she lost all pain in her coccyx, and had not since had a return of it. This happened about six years ago. On another occasion he saw a very obstinate and severe case of coccygodynia, which he had been treating unsuccessfully for a long time and which had a traumatic history, quickly disappear under an exciting family jar. In view of this experience, he believed it always safer at first to consider coccygodynia as a local expression of a general neurosis, and to treat it accordingly.

Dr. J. H. PACKARD asked why Dr. Goodell had preferred the bone nippers to disarticulation in the first case.

Dr. ALBERT H. SMITH asked if Dr. Goodell had removed the entire coccyx. (Dr. Goodell was not sure, but thought so. There had been an abscess in connection with the injury, and the bone was dead and somewhat necrosed. He had cut off one piece with the nippers, and then disarticulated the remainder). Dr. Smith, continuing, said there had been suppurative action, probably following ankylosis. Such a condition might result from injuries received in labor, or from falling astride a chair-back or a rail. Most cases were reflex hysterical or uterine pains, as would be proved by the freedom from tenderness when the finger was pressed on the coccyx while making a vaginal examination. He had never removed the coccyx, because he had seen so little relief from the operation in any cases that had

come under his observation. Why should relief come unless all the nerves and other painful tissues were also removed? He would be glad to hear the result of the operation in the case reported by Dr. Goodell.

AXIS-TRACTION WITH THE OBSTETRIC FORCEPS.—Dr. PACKARD demonstrated a new method of applying axis-traction by an attachment applied to any ordinary obstetric forceps. The device consisted of two steel hooks arranged to catch in the fenestræ of the blades of the forceps, and terminating in rings through which a wooden handle was to be passed. The handles of the forceps were to be lashed together.

Dr. SMITH remarked that Dr. Tarnier's first suggestion was to pass a cord through holes drilled in a widened portion of the blades at the point at which handles were now attached. The hooks exhibited by Dr. Packard did not draw from the right point, and he thought there would be difficulty in adapting them when the head was high.

Dr. GOODELL thought that Tarnier had been anticipated in the cord attachment by another French physician.

THE SIGNIFICANCE OF METRORRHAGIA ABOUT AND AFTER THE MENOPAUSE.—Dr. B. F. BAER read a paper in which he said that metrorrhagia recurring about the menopause was as likely to be the result of disease of the uterus or its appendages as it was at any period previous to that time. The popular belief that floodings at the change of life were physiological often resulted in harm. That the loss of blood was depurative or critical, and that it protected the vital organs from injurious congestion, was erroneous. Where health existed, the cessation of menstruation would be attended by no more aberrations of function than were seen in its establishment. An analysis of twenty-two hundred cases, treated in hospital and private practice, showed that nearly the same number of women sought advice during the establishment and during the decline of menstruation; and it further showed that the numbers rapidly increased as the period of greatest fecundity was reached, and declined after it was past.

Epithelioma of the cervix might result from injury of that organ, but also required some peculiarity in the structure of the tissues which rendered them susceptible to an induced dyscrasia. When a woman, in the midst of the fertile period, suddenly ceased to bear children, there was often some local cause for it. There was some causative relation between acquired sterility and cancer. It was safer to believe the disease of local origin, for we should then endeavor to discover and remove all sources of irritation, and possibly prevent its development. Detailed histories of a number of cases were given to illustrate the truth of the positions assumed. Where the menopause was retarded beyond the usual period, the cause could often be found in some diseased condition connected with the sexual system, and, as a rule, it was an old-standing trouble. When metrorrhagia recurred after the menopause had been fully established, it was almost invariably the result of a pathological change in the tissues of the uterus.

Dr. GOODELL agreed almost wholly with what Dr. Baer had said. He thought the dangers of the menopause much overrated. Cancer and fibroids of the uterus occurred more frequently at that age than any other, and had caused the popular dread. Although hæmorrhage was always pathological, its cause could not always be discovered, and in this "dodging period" serious hæmorrhage might occur and no dangerous condition exist. He would like to believe that cancerous growths had a benign incipency, but could not go so far. The microscopists made many mistakes in ascribing malignancy to growths removed from the uterus. Dr. Goodell then gave a number of cases in which experienced microscopists had given prognoses of early fatal termination, based upon the cell-formation of growths re-

moved from the uterus; but these patients had recovered, and now showed no evidence of any diseased condition. With regard to the small proportion of cancerous growths following laceration of the cervix uteri, he called attention to the large number of Irishmen using clay pipes, and the small number of lip cancers; and yet it was universally acknowledged that the use of a clay pipe was the principal cause of such growths.

Blood-letting is practiced very freely in Turkey and the East, and women, as a consequence, got very stout; such women were more liable to profuse hæmorrhage at the "dodging period."

MALARIAL POISONING IN A NEW-BORN BABE.—Dr. WILLIAM T. TAYLOR reported a case of this sort, as follows:

We have frequently observed fevers of a malarial type in very young children, in some even during the first year, which were ushered in by a convulsion or other prodrome, without a rigor, as occurs in older persons, and their character is only recognized by a repetition of the attack in a day or two. But the youngest subject of this disease which I have met with is the following case:

Mrs. A. R., during her second pregnancy, was affected with malarial fever, and, although she was then residing at the seashore, was obliged to take occasional doses of quinine to control it. She returned to her city residence at the end of the season, but continued using quinine from time to time until the end of her utero-gestation, which was completed in November last, when her babe was born. Her labor was natural and easy, and she had no unfavorable symptoms. The child appeared healthy, was of good color, but was smaller and feebler than her first-born at its birth. As she had a good supply of milk, it soon drew the breast quite vigorously. About one week after its birth the nurse called my attention to "weak spells" which it had occasionally, accompanied by coldness of the skin, a feeble circulation, and prostration, which continued for fifteen or twenty minutes, and were followed by a clammy perspiration. By the application of heat to the body, and giving it a little brandy and water or other stimulant, it would revive. I observed that these "spells" had a periodicity, occurring every two or three days, and, considering them malarial, I gave the mother quinine and valerianate of iron, which, acting therapeutically through the milk, soon caused the "spells" to cease, and the babe became well and fat. I also gave it small doses of the elixir of cinchona for several weeks. The child must have contracted this disease while *in utero* through the placental circulation, for, being born in a perfectly healthy locality, it was not exposed to any external malarial influence. When labor began, the quinine was stopped, and was not resumed until the condition of the child required it, when it soon showed its antiperiodic action by completely arresting these "weak spells," for now the child is perfectly well.

Dr. R. P. HARRIS related a case of parallel character, which had occurred some years ago in a malarious neighborhood. The mother was under treatment before labor. The child had chills and fever when quite young, and was treated through the mother.

W. H. H. GITHENS, M. D., *Secretary*.

MEDICAL SOCIETY OF THE COUNTY OF KINGS.

PATROLOGICAL SECTION.

Meeting of January 28, 1884.

The President, Dr. FREEMAN, in the chair; Dr. BARTLEY, Secretary.

CICATRIX OF THE STOMACH AND STRICTURE OF THE OESOPHAGUS WITH RUPTURE BELOW THE STRICTURE.—Dr. BROWNING showed a specimen, and spoke as follows:

This specimen was taken from a man a little over fifty years of age. He was a patient of Dr. Benton, and had been seen also by Dr. McCollom and Dr. Pratt. The main points in the history of the case have been given me by Dr. Benton.

The subject had long been an habitual drinker, without, however, as it is represented, often getting fully intoxicated. His final trouble dated back a year and a half, beginning with stomach symptoms, dyspepsia, pyrosis, etc. About ten months before his death indications of stenosis of the œsophagus began, and gradually increased so that he could swallow no solid food, and but a spoonful or two of liquid at a time, and this only with effort.

However, at no time had there been complete stoppage of the food-pipe. No history of hæmatemesis. He finally became extremely emaciated, could swallow only a little spirit and water, and this was retained but a short time. Enemas were, of course, tried. Persistent obstipation. Albumin in limited amount had been found in the urine.

In the course of the trouble an ulcer of the stomach had been diagnosed, as also stricture of the œsophagus, although the patient objected to having a sound introduced. Cancer of the cardia had also been thought of, especially in consideration of the patient's age and habits, but the skin had not that peculiar shade so often seen with carcinoma.

In a little material expectorated the day before death I found an abundance of pavement epithelium, mucus, and transparent rhombohedral crystals. He had been troubled a great deal with raising tenacious mucus, said to be very generally the case in stricture of the œsophagus.

He died rather suddenly about five minutes after vomiting some dark-greenish fluid.

Post-mortem in presence of the above-named gentlemen: Heart and lungs apparently normal. The left lung contained less air than the right, and was adherent at its apex only. In the left pleural cavity at least half a pint of dark-green fluid. No further sign of pleurisy.

In the abdomen the large and some of the small intestines were filled with fecal matter. The end of the left lobe of the liver was firmly adherent to the stomach. The latter organ was partly filled with a fluid very similar to that in the left pleural cavity, and, according to Dr. Benton, also to that vomited just before death.

On removing the stomach and œsophagus, the latter was found moderately strictured, beginning about an inch above the cardia and extending from here, though in a decreasing degree, an inch and a half upward. It was quite impossible to force a little finger through this portion. The œsophagus-wall in the strictured portion gradually increased in thickness from above downward to a point a little below the seat of greatest constriction. The hypertrophy affected about equally the longitudinal and circular muscular layers and the submucous and mucous tissue.

The thickest part of the muscular layer extended a little below a marked circular stricture of the intima, and then both longitudinal and circular fibers terminated abruptly.

The mucosa at the stricture was not especially adherent to the underlying tissues. Its surface was not ulcerated, but smooth, and presented few or no rugæ. Below the strictured portion the œsophageal walls were very thin, macroscopically devoid of muscular elements, and the canal was not constricted. It presented the appearance of thin cicatricial tissue. On one side of this part there was a slight depression—as large as the end of one's finger. On the left side of the attenuated part was an oblong opening from above downward. This was evidently a rupture.

The cardia was as permeable as usual, as was also the py-

lorus. The adhesion between stomach and liver corresponded to a large depressed cicatrix on the lower surface of the smaller curvature, clearly the result of ulceration. The ulcer appeared to be healed over, although between this and the cardia the stomach-wall was very thin, and at one point there was an opening believed to be a tear made in freeing the adhesion, since there was no sign of perforation into the abdomen before removal, and it was found easy to enlarge the opening. The smaller curvature of the stomach was almost obliterated by the cicatricial contraction, thus bringing cardia and pylorus very near together—barely an inch apart.

Kidneys were slightly congested, liver normal.

There was considerable discussion by the gentlemen at the time as to the relation of the results found at the autopsy to the course of the disease. With the assistance of the opinions there expressed, and further examination of the preparation, I think it is possible to give a fair explanation of some of the principal features.

His abuse of alcohol produced a chronic catarrh of the stomach, and, either alone or with other unknown factors, finally ulceration. Such catarrh tends to produce atony and even dilatation of this organ. The cicatrization by displacing the pylorus would doubtless further impede the discharge from the stomach. The coprostasis gives additional evidence of the inactivity of the intestinal tract.

The accumulation of material in the stomach, as shown by the autopsy (not only the fluid found in the stomach, but that in the left pleural cavity, and that thrown up just before death, was, doubtless, all held by the stomach), produced the vomiting, and this was made doubly distressing by the stricture hindering the free discharge upward.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Meeting of February 25, 1884.

S. O. VAN DER POEL, M. D., President, in the chair.

THE EFFECTS OF ADDUCTION AND ABDUCTION ON THE LENGTH OF THE LIMB IN FRACTURES OF THE NECK OF THE FEMUR.—Dr. WILLIAM S. HALSTED read a paper with this title. [It will be published in full hereafter.]

Dr. A. B. JUDSON did not feel sure that the result would prove of much practical value. He said this because it seemed to him not only that the fixed point, the superior spinous process of the ilium, lay too close to the center of motion, the acetabulum, but that it also lay too nearly in a line with the acetabulum and the malleolus; in other words, the acetabular angle of the triangle was too obtuse. Certainly, shortening or lengthening, as ascertained by measurement under these different conditions, had not proved of any practical importance when applied in cases of hip-joint disease. His experience with fracture of the neck of the femur had not been sufficiently extensive to enable him to speak of the value of the method in such cases.

Dr. J. A. WYETH also thought the point made by Dr. Halsted was more applicable to cases of accidental lesion of the neck than to cases of hip-joint disease. But such measurements in surgery practically were far from exact. What rendered the uncertainty of measurement still greater was the fact that there might be a normal difference of half an inch or even more in the length of the two limbs.

Dr. HALSTED said his remarks were directed specially to accidental fracture of the neck, and not to cases of hip-joint disease. He did not think that in the former class of cases the objection brought forward by Dr. Judson with relation to the great ob-

tuseness of the angle formed by a line drawn from the malleolus to the acetabulum, and another drawn from the superior spinous process to the same point, was well founded in cases of the kind to which he referred, as was illustrated in the case cited. The practical value of the point made in the paper amounted to this in treatment, that by recognizing the influence of abduction the position of the leg could be changed and the patient saved the necessity afterward of walking with a limp.

THE PATHS OF CO-ORDINATION.—Dr. E. C. SPITZKA then read a paper on this subject. After some introductory remarks, Dr. Spitzka related the following case, which was the basis of his paper:

J. B., aged fifty-eight years, a trussmaker, single, consulted the writer on the 6th of August, 1879, and related the following history: About two years before, while in the water-closet, moderately straining at stool, he suddenly became faint and dizzy; his thoughts were confused for the moment, but he recovered in what appeared to him to be a few seconds. He then noticed, on attempting to dress himself, that his right arm was numb, and, on rising, that his right leg felt as if asleep; there was a feeling throughout the right side of his body as if a sort of musical sensation pervaded it. His dressing occupied some time, as he could not find the buttons with his right hand, and afterward he walked to his office on the next floor without much difficulty. At no time thereafter, up to the period of the consultation, had he observed any actual weakness of any of his extremities. The "singing sensation" disappeared, after having continued some months, and was accompanied by the symptom which persisted up to the date of the patient's death, and which he happily described as a stupid feeling, combined with the numb sensation. He frequently spoke of his right hand and arm as being devoid of intelligence. For some time after the attack his vision was blurred, but there seems to have been no marked diplopia. The numbness was limited to the right side. A few days ago he awoke from his sleep feeling an aggravation of his symptoms, and noted a return of the "singing feeling" on grasping a piece of paper with his right hand. His tongue, which had been a little thick, failed him altogether, but he regained its use in a few hours. He has been unable to carry on the skilled work of his occupation.

On ordering the patient to close his eyes, and then to place his right index-finger on the tip of his nose, he does so, oscillating very uncertainly with his hand, and moving his head toward the finger. He is unable to write his name in the dark, but makes meaningless scratches and smears the paper. The handwriting when the eyes are employed is irregular and scrawl-like as compared with his handwriting before the apoplectic attack; it is, however, still legible, and the characters, aside from an irregularity in size and an ataxic tremor, are bold and distinct. On asking the patient to bear up against the writer's resistance, he uses either too little or too much force (usually the latter) when the experiment is tried on the right side, and shows the normal balancing of his forces on the left. At the same time his movements have the jerky, spasmodic character on the right side previously referred to. There is nothing of the kind observable on the left side, and neither the tests made for ascertaining his sensibility, nor those made to elicit his co-ordinatory functions, support the patient's statement that his disorder has lately involved the *left* foot. There are no trophic disturbances of any kind.

September 24, 1881.—Has suffered from a diarrhoeal complaint, with bowel tenesmus, for three days past; this morning had a normal passage. Complaints of alternate swelling of the eyelids. The patient requires firm pressure with the points of a blunt aesthesiometer to appreciate them at all, and it is very uncertain about their locality and number. A sharp aesthesiometer is appreciated as before. A repetition of all tests was made. The ataxia of movement is increased in the arm; the gait is the same. No muscular weakness in the extremities. There is a feeling in *both* feet as if a "thousand extremely fine needles were run through the stockings, and dashed through the deep flesh of the foot." This is much worse in the right foot, but distinctly felt in the left also.

26th.—The patient, after doing considerable running around the

city, and becoming overheated, the day previous, awoke unable to use his tongue, but, after a few minutes, regained its use. All his subjective sensations, particularly the dizzy sensation, were aggravated. The left knee-jerk was increased.

February 8, 1882.—Another attack of a similar character; the speech disturbance is much more permanent, however.

19th.—He fell down in a faint-like condition while crossing the Bowery; did not lose consciousness entirely, as he asserts, but was much bewildered and alarmed. Two tramps lifted him up and led him to his office. The expression of the patient is that of an absent-minded person; there is some contraction of the right pupil.

June 22d.—I was called to the patient's residence for the first time. He has taken to bed, on account of an increase in the dizzy feeling and general malaise. He is able to walk about as well as since his illness, but has become apathetic and somnolent. His right hand is slightly œdematous. He takes a deep breath frequently, and yawns a great deal. The "drawn-together" feeling is less marked than formerly on the right side.

August 4th.—He passes his urine unconsciously. There is slight right hemiparesis, with paraplegic weakness of the lower extremities; the right hand is so much swollen that the patient is hardly able to close it. The tongue, as a whole, inclines to the right, but the point deviates to the left; a coarse tremor is observed in it. He does not appreciate when his bladder is full, though his general consciousness is not noticeably impaired. He recognizes a difficulty in finding the right words to express his meaning. His speech otherwise is thick.

20th.—A chilly sensation was noted after the last visit, which still continues; it is general, but more marked in the trunk and right side.

25th.—Passes water and feces involuntarily, and wanders in mind. Occasionally he speaks deliriously. The cold sensation has continued since the last visit, and is intense and agonizing.

27th.—The breathing has been stertorous day and night in spells for the last two days; there is right ptosis, the previous ptosis on the left side not being noticeable; the right pupil continues extremely myotic. The patient got up and passed water in the chamber three times without assistance, and without exhibiting any considerable motor impairment to the relatives.

At the autopsy, softened areas were found in the left cerebral hemisphere, which exhibited the characteristic appearances of recent necrotic softening; evidences of organization were found only in the periphery of the focus of the right frontal lobe.

A focus of disease in the pons was determined, on comparing the sections made of that part of the isthmus, to consist of a cavity with partly organized walls and intense contiguous tissue changes. At the level of the motor nucleus of the trigeminal the cavity was reduced to a mere horizontal slit, while the area of tissue change around it occupied nearly the entire field of the lemniscus (fillet), failing to reach the rhaphé by two millimetres, and extending laterally to the motor root of the fifth pair, without in any way involving it. In lower sections, the cavity gradually became larger and advanced ventrad, involving the transverse fibers of the pons immediately below the lemniscus field. The contiguous tissue change involved the rhaphé, and, in diminishing intensity, extended across the median line about two millimetres and a half. Still further caudad, the walls of the cavity became irregular, and hardly a millimetre behind its greatest diameter it came to an end, failing to involve the facial-nerve nucleus, or the roots of the sixth pair.

The original lesion in the pons, Dr. Spitzka thought, must be regarded as hemorrhagic, the cavity as a resorption-cyst, while the contiguous lesion consisted in the inflammatory reaction of the neighborhood. There had probably been recurrences of hemorrhage in the neighborhood of the original one, which widened and extended the area of disease downward, and whose last exacerbation was represented in hæmatozin-colored granules.

Connected with the diseased focus, and merging more or less gradually into the area of "reactive" and contiguous change, there were two systemic degenerations of nerve tracts—a descending one, limited exclusively to the stratum intermedium,

and an ascending one, involving the lateral parts of the lemniscus. The former was the more complete and clearly outlined of the two.

If we conceived of the degenerated fields as an entity, the column they represented might be aptly described as comparable to a rod whose upper end was triangular and on the left side of the rhaps, whose middle portion was encroached on by an olive-shaped excavation, and whose lower end, breaking up into separate strands, was bent rather sharply across the middle line, and at the same time curved dorsad so as to terminate in the nuclei of the posterior columns. As a whole, the degeneration corresponded to the known relations of the inter-olivary layer of Flechsig, the lower continuation of the stratum intermedium of Meynert, and the lower portion of the bundle from the pes to the tegmentum of Henle. All these were terms applied to one and the same nerve tract. Its connection with the nuclei of the posterior columns, surmised by Flechsig, and anticipated somewhat crudely by Meynert, was established as a fact by this case, for the degeneration could be traced among and into these nuclei, and not beyond them nor into the spinal cord.

But not alone were the appearances of the sections changed as to the differences in the tints of the healthy and diseased areas in both stained and unstained specimens; the consecutive shrinkage of the degenerated area had led to alterations in position and shape of neighboring parts. Thus, the rhaps was bent, with the convexity of the bend toward the degenerated area. The left pyramid was slightly drawn up, as it were, into the substance of the oblongata, as if to occupy the void which would otherwise have been left by the shrinking stratum intermedium; at the same time it had increased in the dorso-ventral, at the expense of the transverse diameter, as an expression of the shrinkage of the degenerated area from side to side. The fibræ arcuate, passing from the healthy side across the median line through the diseased area, while intrinsically healthy, ran an unusually undulatory course, owing to the shrinkage of their matrix. While the average area of the left side of the oblongata had suffered in its ventral half by the shrinkage of the left stratum intermedium above the decussation of the lesion, it was the upper part of the right side which showed some diminution in area below this decussation.

The microscopic characters throughout were the same, and such as were to be found in characteristic cases of secondary degeneration. There was scarcely a nerve-fiber left in the most ventral part of the degenerated field, either in the upper or in the lower level.

From a study of the case, Dr. Spitzka deduced the following propositions:

1. The so-called lemniscus layer contains in its mesal portion an individualized column of fibers of high physiological importance, which decussates in the so-called sensory decussation of Meynert.
2. The *stratum intermedium*, as this bundle should be called, for reasons to be advanced farther on, is a tract mediating an essential factor of voluntary motility—co-ordination.
3. The ataxia of movement observed in destruction of this tract is not due to a loss of tactile sensibility. The latter was not sufficiently impaired to account for the absolute unilateral ataxia attributable to the division of the stratum intermedium.
4. The stratum intermedium is not purely a centripetal tract. It degenerates centrifugally.
5. Physiologically, it appears to be, in part at least, centripetal; this is shown by the paræsthesias and hypæsthesia complained of by the patient.
6. While the stratum intermedium is probably the continua-

tion of the column of Goll, and, in part, of that of Burdach, toward the cerebrum, the secondary degeneration of the spinal part of this (ideal) tract advances centripetally, while the cerebral portion degenerates centrifugally, the point to which both converge being the nuclei of the posterior columns.

7. Flechsig's statement that there is no direct continuation of the posterior columns into the piniform decussation, but that they terminate provisionally in their nuclei, is demonstrated beyond peradventure by this case.

8. While Flechsig is also sustained in his denial of a gross connection between the so-called upper pyramidal decussation of Meynert and the pyramids proper, yet there is an intimate connection between the stratum intermedium and the pyramid of the same side, extending along the known course of the former tract from its decussation up to the lower part of the pons. It is possible that the connection between the sensory periphery and the pyramids, which Meynert attempted to establish, really exists through the medium of this interchange, though in much lesser degree than the distinguished founder of modern cerebral anatomy surmised.

9. The system of fibers which is represented in the fasciculi arching through the olivary nuclei, those of the external arciform group—and which are not without reason supposed to connect the posterior columns, or rather the latter, through nuclear intervention, with the restiform column—is entirely independent of the stratum intermedium. Nor have the olivary nuclei, or any of the tracts connected with them, a connection with the stratum intermedium.

10. The vertical fibers of the trapezium appertain to the stratum intermedium.

The paper was discussed by Dr. V. P. GIBNEY and Dr. E. C. SEGUN.

The Committee on the Collective Investigation of Disease made a report (read by Dr. DAVID WEBSTER) recommending the sending of a circular to the members relative to the subject of intestinal obstruction.

The Delegates to the Medical Society of the State of New York reported (through Dr. C. L. DANA) that all the delegation had been present at the State society meeting, with the exception of five. Three of the members of the county delegation had been made permanent members of the State society. Later in the evening the society elected the following members to fill these vacancies: Dr. L. EMMET HOLT, Dr. M. JOSIAH ROBERTS, and Dr. W. M. McLAURY.

THE COLLEGE OF MIDWIFERY.—Dr. P. C. COLE moved the adoption of certain resolutions approving of the founding of a college of midwifery. Some discussion followed, and it was finally ordered that the President appoint a committee of five, to report on the subject at some future meeting. The President appointed Dr. LEE, Dr. CHAMBERLAIN, Dr. WARDEN, Dr. JACOBUS, and Dr. PARTRIDGE.

Resolutions were passed approving of the work of the Society for the First Aid to the Injured.

Dr. J. W. HOWE was appointed a delegate to the International Medical Congress, to meet at Copenhagen.

NEW YORK SURGICAL SOCIETY.

Meeting of February 26, 1884.

ROBERT F. WEIR, M. D., President, in the chair.

PLASTIC OPERATION FOR RODENT ULCER.—Dr. A. G. GERSTER presented a patient who showed the result of three operations. A woman, thirty-four years of age, married, presented herself to him about one year ago with a flat epithelioma, or what the older writers called rodent ulcer, on the left cheek. The disfigure-

ment was very great. The size of the deeply depressed ulcer was about that of a silver half-dollar. The main body of it occupied the region of the masseter muscle, and there was pseudo-ankylosis of the lower jaw due to scirrhous contraction of the new growth. Dr. Gerster proposed to remove the ulcer, and made a good prognosis so far as relapse of the disease was concerned, basing it principally upon the fact that none of the adjacent glands were affected. The patient, however, did not consent to be operated upon at that time. She returned in September last, with the ulcer twice as large as it was when he first saw her. Perforation into the oral cavity had taken place in the middle of the ulcer, and there was a continuous oozing of saliva from the opening. She then consented to submit to the operation, and, on the 27th of September, 1883, he removed the entire cheek, together with a portion of the horizontal part and the angle of the lower jaw on the left side, commencing at about two inches from the median line, and also a small portion of the alveolar process of the superior maxilla. When the operation was finished the tongue could be seen for its entire length, and also the jaw which remained. He did not make an effort to close the wide opening by a plastic operation at that time, but waited until cicatricial contraction should diminish the size of this enormous defect to such an extent that a plastic operation could be performed, the object of which would be twofold: first, to form a new cheek, and, second, to prevent the recurrence of ankylosis of the lower jaw, which would have necessarily followed in consequence of cicatricial contraction had no plastic material been interposed between the two edges of the wound.

In order to accomplish this he was obliged to follow a plan which was not original with himself, although the only case in which the method had been adopted, so far as he could ascertain, was one reported by Gussenbauer, in Langenbeck's "Archiv," who performed a similar operation on both cheeks, the operation being rendered necessary by noma. Dr. Gerster followed the same plan substantially in his case. The first indication, then, was to give the oral cavity a lining. On the 25th of October, therefore, he raised a tongue-like flap from the temporal region one inch and three quarters wide and three inches long. It was turned into the defect so as to present the epidermal surface toward the oral cavity. None of the mucous lining of the cheek could be saved at the first operation. There were, therefore, no soft parts remaining to which this flap could be attached, and, consequently, he drilled three holes in the alveolar process of the lower jaw and four in the alveolar process of the upper jaw, and to these the flap was attached by silver-wire sutures. Primary union ensued, and a little more than four weeks later he proceeded to cover up the granulating surface corresponding to the lining of the oral cavity. To do this he raised a flap from the neck, turned it up into the space, and fastened it with a number of silver-wire sutures. This flap necrosed at its apex for a short distance, because of the inequalities of the surface and lack of precise adjustment throughout its entire extent.

Dr. Gerster presented this patient because the case was not yet completed, as there was still one deformity to be corrected, namely, the angle of the mouth was drawn to the left side; and when that correction had been made he would present the patient again to the society. At present she was able to open the mouth wide, and her ability to do so was improving from day to day.

OSTEOTOMY FOR GENT VALGUM; MACLEWEN'S METHOD. Dr. C. T. POORE presented a patient, a girl three years and a half old, upon whom he had performed osteotomy on the right leg. The operation was performed three or four months ago, and was resorted to because he was unable to correct the deformity by means of mechanical appliances, the external lateral ligament

having become relaxed. It was the youngest patient upon whom he had ever performed the operation, and the correction was perfect.

EXCISION OF THE ANKLE JOINT, WITH SPECIAL REFERENCE TO TECHNIQUE AND AFTER-TREATMENT.—Dr. F. LANGE read a paper with this title. [See p. 295.]

A NEW METHOD OF TREATING LARGE BONE CAVITIES IN THE LOWER END OF THE FEMUR IN ADULTS.—Dr. LANGE also read a paper with this title. [See p. 297.]

Dr. L. A. STIMSON said he had recently performed excision of the ankle joint, and hoped soon to be able to present the patient to the society. He also hoped that the case would show less lateral mobility than that shown by most of the cases presented by Dr. Lange, for he had preserved the malleoli in part, although removing the astragalus entire. The operation was performed after the method more recently described by Vogt, by making a longitudinal incision beginning about an inch and a half above the articular surface of the tibia and passing downward along the border of the extensor tendons for about three inches, with a short lateral incision from the lower part of this toward the tip of the external malleolus. Through this incision the astragalus was easily removed and a very full view of the ankle joint was obtained. He endeavored in his case to remove all the synovial membrane, with the preservation of the greater part of the two malleoli. It must be said, however, that in his case the disease manifested itself mainly in the synovial membrane, and only slightly in the tibia and fibula. The feature to which Dr. Lange had directed attention, namely, the displacement of the axis of the limb backward upon the foot, appeared also in his case, and he attributed it, as Dr. Lange had done, to the effect produced by pressure upon the heel, bringing the line of the weight of the body upon the foot somewhat posterior to the point where it normally fell.

Dr. LANGE thought that perhaps the operation described by Dr. Stimson would be best if the disease involved the astragalus alone, but he thought it might not be possible to see all the parts involved, especially if the disease was situated pretty high in the tibia. In such cases the longitudinal incision could not be dispensed with. He also thought the principle of doing as little injury and leaving the parts in as nearly a normal condition as possible was what especially commended Langenbeck's operation.

The PRESIDENT remarked that he had had the opportunity of seeing two cases in which Busch's method of resection of the ankle was performed by making a transverse incision across the sole of the foot. Each of the different operators said the method gave an admirable command of the parts. The result in both cases, however, was a permanent non-union of the os calcis, with considerable necrosis of the same, a result which it was apprehended might occur.

The President also remarked that last summer Dr. Neuber showed him two or three cases of necrosis of the head of the tibia where he had, after the removal of the diseased or dead bone, transplanted a V-shaped flap of skin into the bottom of the cavity and fastened it there by a nail. At the time they were exhibited they were doing admirably. Since then Dr. W. T. Bull had treated one case of tibial necrosis in the same way at the New York Hospital.

Dr. LANGE had tried the same method lately in extensive necrosis of the tibia, but without complete success, probably for the reason which he had seen repeatedly, that in necrosis, if the operation must necessarily be performed where there was a copious discharge, with some infiltration of the tissues, a good deal of suppuration would occur in spite of the use of strict antiseptic precautions. In the case alluded to he was obliged to operate. The patient, a girl of perhaps five years of age, was losing ground,

and bectic had developed in spite of all efforts to build her up for the operation. The discharge was copious before and after the operation, and primary union did not take place. His operation, however, had proved somewhat beneficial, and would probably make recovery more speedy, because the inverted lateral flaps, though not fixed by primary union, had still contracted so as to diminish the bone cavity. He regarded the condition of the parts where primary union was expected as a very important factor. Infiltrated tissues, secreting pus somewhat freely, would continue to discharge freely for some time, though the secreting surface might be removed. Apparently an irritant lay within the tissue at some distance from the wound, and, being somewhat active, must first be given the chance to disappear, either by absorption or by secretion upon the free surface of the wound.

Dr. GERSTER had resorted to this procedure in two cases. In one he had to deal with a relapse of carious affection of the lower part of the diaphysis of the femur. The patient had been operated upon fourteen or fifteen years ago in Europe, and had been doing well ever since; but recently the disease returned, and an abscess formed corresponding to the extensive cicatrix which occupied the inner aspect of the thigh. It was incised, and, after the disappearance of the febrile symptoms, Dr. Gerster attacked the disease itself, exposed the bone, and formed as shallow a trough as he could in the lower portion of the diaphysis of the femur. He then loosened up the skin on either side, turned the flaps into the bottom of the cavity, and fastened them in the manner mentioned. The patient had no fever, but, the dressings getting soiled, he removed them on the twelfth day, and found that to a considerable distance the old cicatricial substance had ulcerated under the influence of the profuse secretion which had taken place from the cavity. Nevertheless, the flaps did not recede, as they did in these operations when the cavity was plugged after the old-fashioned way.

In another case Dr. Gerster performed necrotomy upon the head of the tibia, and, if he had been able to obtain sufficient skin to reach to the bottom of the cavity, he thought the result would have been even more satisfactory than it really was. As it was, the skin flaps were so short that he was obliged to leave uncovered a strip of bone in the median line about one third of an inch wide. Primary union took place as far as the cutaneous flaps reached, and there was no doubt that the recovery of the patient was very much hastened by the procedure. He also noticed that the deep depression of the cicatrix and skin was diminishing, and finally was now on a level with the normal surface of the tibia, and that apparently the bottom of this depression gradually filled up with bony substance.

NECROSIS OF THE LOWER JAW DUE TO PHOSPHORUS POISONING.

—Dr. J. C. HUTCHISON presented the greater portion of the body of the lower jaw removed from a woman, forty-two years of age, who came under his observation about a year ago. She came from Frankfort, Herkimer County, where she had been at work in a phosphorus factory, and from which place a number of patients had been received at the Brooklyn City Hospital. She gave the following history: Two years ago she had an ulcerated tooth on the left side of the lower jaw, which was extracted, and at the end of two weeks she returned to her work in the factory. About one year subsequently small pieces of bone began to discharge from the jaw, and she entered the hospital for the purpose of having an operation performed. Circumstances were such that it was impossible for her to remain as long as was desired before operative measures were resorted to. The operation was performed and the bone exhibited was removed. The patient returned to her home, and Dr. Hutchison heard from her three months subsequently, when she stated that a splintum of bone had come out since her return. He wrote

to her to let him know if she had further trouble, and, from the fact that he had not heard from her since, he concluded that complete recovery had ensued. He thought the specimen showed that the operation might have been deferred with advantage if the patient could have consented, and with less loss of bone.

APHASIA FOLLOWING EXTERNAL INJURY OF THE HEAD WITHOUT WOUND OR CONTUSION OF THE SCALP.—Dr. H. B. SANDS narrated a case of injury of the head which to him seemed to be somewhat remarkable. A lady, aged forty-eight, residing in Hartford, Conn., two weeks before his visit was thrown from a sleigh and probably struck upon her head. She was picked up in an unconscious condition, and, on examination soon afterward, the attending physicians were unable to find any signs of external injury of the head, although there were marks of contusion of the neck and also of the lumbar region. A few hours after the injury consciousness began to return, and vomiting occurred. It was also noticed that the pupil of the right eye was a little larger than that of the left, and was sluggish, although it responded to light.

The singular feature of the case was the existence of aphasia, which, though not extreme, was well marked, and presented the usual characteristics of aphasia resulting from purely pathological causes. Some change in the mental condition of the patient was noticeable, showing itself by a disposition to talk, and by an unnatural degree of mirth. When Dr. Sands saw the patient she talked quite rapidly, using rather often a wrong word. In reading aloud, about one word in every line was not the one she intended to use. She was aware of the infirmity, and became easily fatigued by mental exertion, experiencing pain on the left side of the head whenever she attempted to carry on a conversation for any length of time. The right hand appeared a little weak.

Dr. Sands was unable to recall a case exactly like the one related, and inquired what had been the experience of the members with regard to the production of aphasia from a blow upon the head. The patient's health was otherwise good, and there was no reason to suppose that any disease existed at the time of the injury. The urine had been examined and found to be normal.

In endeavoring to account for the condition, the possibility of aphasia occurring simultaneously with the accident as a result of some cause not traumatic was taken into consideration. It seemed probable, however, that the lesion was due to the injury, because she presented the usual signs of concussion, and the return of consciousness was accompanied by vomiting. Moreover, examination of the heart failed to discover any valvular disease, and, as already stated, the patient's general health prior to the occurrence of the accident was known to be excellent.

Dr. GERSTER mentioned a case in which aphasia took place in consequence of an apoplectic seizure during the healing of a wound made for the removal of cancerous breast, and was apparently caused by embolism. The patient was sixty-two years of age. The left breast was amputated and the axillary space evacuated. Antiseptic dressings were applied, and the wound was healed on the ninth day, when the patient got up and walked out into an adjoining room, lost her consciousness, and fell. She was taken up and put into bed, and when he saw her, on the following morning, she was unable to talk. There was hemiplegia, which disappeared during the course of the next two weeks. Deflection of the tongue and inequality of the pupils were noticed. In the course of three weeks she began to talk again, and the curious feature in the case was that she forgot the German language and spoke only her native tongue, that of Bohemia. She was unable to write, but was able to draw rough

outlines of simple objects. She gradually learned certain letters, but was unable to write all letters. It was therefore a case of agraphia complicating aphasia. Recovery was gradual, and finally was so complete that she was again able to speak in German.

Her circulation was very poor, and three days before the apoplectic seizure Dr. Gerster found evidence of hypostatic congestion of the lungs. Whether this partial solidification of the lung was due to transmission of a clot from the wound into the lung, and whether infarction of the lung followed, from which an embolus was detached and, being carried into the circulation, produced the hemiplegia, he was unable to say. The trouble seemed, however, to be in direct connection with the operation. Also, whether the fall was from the apoplexy, or whether the fall produced the apoplexy, he was unable to determine positively.

Dr. W. S. HALSTED remarked that the hemiplegia in Dr. Gerster's case could be explained without supposing the formation of infarction, and on the ground of the free anastomosis which had been demonstrated to exist in the lungs—so free that emboli might be carried directly through the lungs into the brain, independently of the formation of an infarction.

Dr. A. C. POST referred to a case under treatment many years ago in the New York Hospital, that of a Swedish sailor boy who received a concussion of the brain, and, while suffering from the cerebral disturbance, forgot his English entirely, and was able to speak only his native language.

Dr. LANGE referred to a case of disturbance in the use of language after injury produced in the temporal region by being stepped upon by a horse. The man showed no deficiencies with reference to the number of words, but rather in using them intelligently. He answered questions very quickly, and words seemed to occur to him more than he needed. The case was not a recent one. A number of weeks elapsed after the injury before an operation was performed, and a large number of pieces of bone were removed, but without giving any permanent benefit. At times the patient was restless, and had to be watched and partially restrained. There were no paralytic symptoms. Finally he was discharged uncured.

NEW YORK ACADEMY OF MEDICINE.

Meeting of March 6, 1884.

FORDYCE BARKER, M.D., LL.D., President, in the chair.

THE secretary read a letter from Dr. H. P. FARNHAM, presenting his check for one thousand dollars as a donation to the Academy. By a vote of the Academy, Dr. Farnham was made one of its benefactors. Other donations were also acknowledged.

THE DETECTION OF ALBUMIN IN URINE, WITH A REVIEW OF THE METHODS RECENTLY ADVANCED.—Dr. GEORGE B. FOWLER read a paper with this title. If, in some respects, he said, he treated the subject in a somewhat elementary manner, it was for the purpose of making himself perfectly understood. The kinds of albumin might conveniently be classified as native and derived. The native albumin of urine was that which normally existed in the serum of the blood in the proportion of one ninth of one per cent., and was called serum albumin. A great many substances were capable of demonstrating the presence of serum albumin, but many of them were not applicable to its demonstration when present in the urine, because of the complex nature of that fluid. We should consider those reagents which were most readily applied and required the least degree of skill, but which were of practical value

The following methods were given for detecting the presence of serum albumin in the urine:

1. *Heat*.—When serum albumin was subjected to heat it began to grow opaque at about 60° C., and coagulated at about 73° C. The solid coagulum of heated serum albumin contained about nine per cent. of albumin. The paralbumin present could not be distinguished from the albumin, as both were alike coagulable by heat. When diluted, the reaction of albumin to heat was less; the coagulum was less firm and the opacity less marked. If to the pure albumin an inorganic acid were added, no coagulum would be formed by the application of heat, for by the addition of the acid the albumin had been converted into an acid albumin which was not coagulable by heat. This was an important practical point, as doubtless many physicians made the mistake, in using, for instance, the nitric-acid test, of adding the acid first and then applying heat, expecting to find the albumin precipitated if any were present in the fluid. This was also true of very alkaline urine. If to serum albumin a considerable quantity of an alkali were added, alkaline albumin would be formed, which was not thrown down by heat. Very alkaline urine, therefore, should receive a little acid, to neutralize its alkalinity, if we wished to detect the presence of a trace of albumin.

It would be seen that the derived albumins were formed when a fluid in which albumin was present contained an excess of an acid or of an alkali, and such derived albumins had their own reactions. By diluting an alkaline or an acid urine up to the point of neutralization, a precipitate of albumin could be formed by the application of heat. The proportion of albumin which heat would detect was about two tenths of one per cent. Heat applied to a solution containing that proportion of albumin would cause a slight opacity. It was necessary, however, that the solution be neither strongly alkaline nor strongly acid.

2. *Mineral acids* would precipitate albumin, and one of the most delicate and best tests for the presence of albumin was nitric acid. This agent would detect one tenth of one per cent. of albumin.

3. *The neutral salts*, subsequently acidulated, would precipitate albumin, and the preparation of chloride of sodium used by Dr. Roberts, of Manchester, England, was considered a delicate test, although Dr. Fowler did not regard it so highly as ferrocyanide of potassium. With it one could detect the presence of a one-per-cent. solution of albumin. The brine, when kept awhile, was open to the objection that the salt would form crystals along the stopper and the mouth of the bottle. Ferrocyanide of potassium, with a weak acid, was capable of revealing one tenth of one per cent. of albumin.

Picric acid, which was first brought prominently forward as a reagent for the detection of albumin by Dr. Johnson, of England, was a very delicate and excellent test, and would show the presence of one tenth of one per cent. of albumin. It was open to the objection that it also precipitated the peptones, the urates, and quinine, but, if these substances were present, they would disappear on the application of heat. It was necessary in using picric acid to add an equal bulk of the acid to the urine; if but a small amount of the reagent were employed, the precipitate which it caused would readily disappear on shaking the test-tube.

Dr. Oliver, of London, had recently introduced the *tungstate of sodium*, first employed by a Frenchman, as a test for the presence of albumin in the urine with the presence of a weak acid. It showed the presence of one tenth of one per cent. of albumin.

But the most delicate test which had been introduced was that of *potassio-mercuric iodide*, which was made with iodide of potassium, 3.32 c. c.; bichloride of mercury, 1.35 c. c.; and

water, 100 c.c. It was a perfectly clear and transparent liquid, and, when added to albumin in this state, produced no effect, but, with the addition of a weak acid, such as citric or acetic, a marked coagulum would be formed. It revealed the presence of one tenth of one per cent. of albumin.

The importance of being able to examine urine for the presence of albumin at the bedside of the patient was generally recognized, but until recently no convenient method for accomplishing this had been presented. The object had now been attained, however, by Dr. Oliver, with the use of his test-papers. The test-paper could be formed by saturating paper with the solution of tungstate of sodium, with potassio-mercuric iodide, or with the ferrocyanide of potassium, and other papers acidulated with citric or acetic acid. Let the papers dry, cut them into small strips, put them into a box with a partition, and, when it was desired to examine a specimen of urine for albumin, put one of each of the two kinds of paper into the fluid, and, if albumin were present, it would be seen to fall in a cloud. The most delicate of these tests was that with potassio-mercuric iodide, which distinctly revealed the presence of five one-hundredths of one per cent. of albumin. Indeed, the test was so delicate that in nearly every specimen of urine, whether from the sick or the apparently healthy, a slight precipitate of albumin was caused.

The author demonstrated the use of these several reagents, and expressed special preference for the test-papers of potassio-mercuric iodide prepared by Dr. Oliver. Nitric acid, picric acid, acidulated solution of ferrocyanide of potassium, and tungstate of sodium were all very good and reliable tests.

Dr. E. D. Hudson said that, as had been suggested by the President, the general practitioner of medicine regarded the examination of urine for albumin from a practical point of view; he wished not only to be acquainted with the most convenient and reliable methods for determining the presence of albumin, but also to be informed of the significance of that material when it was present. But, limiting his remarks to the methods of examination, he said that he had kept himself informed with regard to the new reagents which had been introduced, but he had been, and was now still more, convinced that for the busy practitioner none of the new methods were likely to prove more practical and reliable than the old one of heat and nitric acid. He did not think that the diagnostic significance of the presence or absence of albumin was such as would justify us in neglecting further examination by the microscope in a case of suspected renal disease. As phosphates were so commonly present in urine, and were precipitated by heat, he made it a custom to keep a vessel of ice-water on the table, and, immediately after getting a precipitate from heat, to place the tube in the cold water; by the time another specimen had been examined, the phosphates, if they were present, would have become dissolved again.

Dr. GASPAR GRISWOLD said there were two points from which to view this subject; one was the chemical, the object of which was to detect the least possible amount of albumin; the other, the clinical, the object of which was not so much to detect the least possible amount of albumin as to furnish a convenient and practical method. The mere presence of a small amount of albumin in the urine was not now considered of such serious significance as formerly, and it was probable that the old heat and nitric-acid tests were all that were needed from a clinical standpoint. It was important to have a perfectly clear specimen of urine, and, if necessary, liquor potassæ should be added. It was further necessary to view the specimen against a dark background, when but a trace of precipitate was present.

Dr. C. DOREMUS heartily indorsed the remarks of Dr. Griswold regarding the distinction between the clinical and the chemical standpoints of viewing methods of examining urine

for albumin. The test-papers of Oliver might be very convenient for use at the bedside. The results of the most delicate tests were apt to be obscured by the want of a perfectly clear specimen of urine. The ferrocyanide of potassium and acid test was a very good one.

Mr. MUNN had been able to detect the presence of albumin in the urine after the use of a reagent by placing it in a pencil of light as it came through a hole in a dark window-shade, when others had failed to do so.

Dr. MAXWELL thought there was but little difference between picric acid and tungstate of sodium as regarded their delicacy as tests for albumin; but we should not depend upon a single reagent; it was always safer to apply several different tests in any given case. The mere presence of a small amount of albumin in the urine, without other signs or symptoms, he did not regard as of serious significance.

Dr. FOWLER, in closing the discussion, agreed with the last speaker, that entire reliance should not be placed upon a single test. He could not agree with Dr. Griswold that we should not go into unexplored fields; it had not been determined that the traces of albumin revealed by the more delicate tests were not of clinical significance. That peptones were sometimes present in urine he had witnessed, and the best test therefore was the reaction with Fehling's solution.

Reports on the Progress of Medicine.

OBSTETRICS.

By ANDREW F. CURRIER, M.D.

THE COMBINED METHOD OF TURNING IN PLACENTA PRÆVIA.—Dr. C. Behm ("Ztschr. f. Geburtshülfe u. Gynäkologie," ix, 2) refers to the method which was described by Braxton Hicks in 1861, and to the literature of the subject, in addition to giving a somewhat extended notice of his own experience, involving fifty-three cases with this complication, in the clinic of Professor Gusserow, at Berlin. These cases are divided into two series, the first numbering thirteen, the second forty. Those in the first series were treated by the old method of version; thirty of those in the second by the combined method; the remaining ten required other procedures. The thirteen mothers gave birth to fourteen children, and the mortality was four for the mothers and ten for the children. As to the insertion of the placenta, in three cases it was marginal, in five lateral, and in five total or central. Of the forty cases in the second series, there were no deaths on the part of the mothers, but eight were the subjects of fever, and one suffered with hemorrhage on the seventh day of the puerperium. Of the forty children, nine were born alive, five of whom were mature, two premature, and two with vital defects. Of the thirty-one dead children, six were mature, eleven were premature, and fourteen had vital defects. Notwithstanding the small percentage of survivals on the part of the children, the author considers the results excellent, and would so consider them even had all the children been lost, when the peculiar conditions attending this complication are born in mind.

The advantages of the combined method of turning are summed up in the avoidance of sepsis, which it insures, and also the limitation of the loss of blood, by means of the tamponade which is effected by the breech of the child. Turning having been accomplished, the author differs with Spiegelberg, Fritsch, and others in their view that extraction should be as rapid as possible. In twenty-four of his cases in which he noted

the interval between turning and extraction it varied between one half-hour and eleven hours, birth taking place in the largest number between two hours and two hours and a half after turning. In the interval the strength of the patient should be re-enforced, and stimulants are regarded with more favor for this purpose than any method of transfusion. As a means of preventing atonic post-partum hemorrhages, this method of turning has answered perfectly in the author's experience, and no accidents of this nature occurred to him. The aphorism which he proposes for the treatment of placenta previa cases is *haste, with delay*—haste in performing combined turning, delay in extraction.

AXIS-TRACTION WITH THE OBSTETRIC FORCEPS.—Dr. J. F. Le Page ("British Medical Journal," Oct. 2, 1883) remarks upon the great diversity of opinion in regard to the proper use of the forceps among those, even, who have had large experience and are capable of giving an intelligent opinion. A great number of eminent men are quoted, as well as their diverse opinions. The force which nature exercises in accomplishing delivery he declares is intermittent axis-propulsion, and during the intermissions the head of the fetus is adapted to the easiest diameters. The force is always applied in the same line—that of the spinal column. By using powerful leverage on the soft parts, or by forcibly dragging the head, without regard to diameters, through the pelvic canal, we are not acting on this line. If traction is to be exercised, it should be with an instrument which is capable of great freedom and range of movement, the movements being unrestricted and under the control of the operator. In some cases we should not forget that the office of the forceps is not that of a tractor or a lever, but that of a compressor. During the intervals of uterine contraction very gentle rotatory movements should be imparted to the head to aid its adjustment. If the foregoing statements are true, neither the straight nor the curved forceps accomplishes its desired end; therefore the author proposes a new forceps, which has a strong brim and perineal curve, and an adjustable lever. The handle is in a line parallel with that of the blades. It is practically a straight forceps, but, with the lever, traction can be made backward in the axis of the brim. With the lever and handle combined, flexion, rotation, and extension may be assisted or altogether effected, and at the same time the line of traction is independent and can be continued throughout without any variation from the axis of the canal.

AXIS-TRACTION AND OSCILLATION WITH THE OBSTETRIC FORCEPS.—The object of a note by Dr. Robert Barnes (*Ibid.*, Nov. 3, 1883) seems to be, in part at least, to correct a misunderstanding as to his views in regard to the necessity of traction. The statement, in his "Obstetric Operations," that "traction is hardly called for at all," he affirms applies only to a very limited class of cases, in which there exists no anatomical disproportion. [This would seem very much like a weakening on the part of Dr. Barnes with respect to the position which he has heretofore maintained.] He admits that progression is supplemented by traction, and that this, together with the normal movements of the fetus, favors progression and adaptation, with the minimum waste and misdirection of force. As to oscillation-movement, he thinks that when this is very gentle, with the lock of the forceps as the fulcrum of the lever which is formed by each blade, there need be no fear of dangerous pressure upon the maternal soft parts. Slight oscillation will act as an aid to progression.

LAZAREWITCH'S STRAIGHT FORCEPS WITH PARALLEL BLADES.—Massalitinoff ("Ann. de gynéc.," Jan., 1884) states that the main object of this forceps is to avoid the compression of the foetal head which is inevitable in a *crossed* forceps. It was presented to the late International Congress at London, and

afterward, in 1883, it was exhibited at the exposition at Moscow. The excellences of the instrument consist in the absence of the pelvic curve, and in its parallel blades, which are fastened, by means of a pivot and screw, in the handle of one blade, and a hole in the other into which the pivot is mortised. The instrument admits of a maximum separation of the blades at the tips of two centimetres and a half, without altering the parallelism of the handles. It therefore resembles somewhat the old Chamberlen forceps. The advantages claimed for it are the following: 1. On account of their mobility, the blades can be perfectly adapted to the head as well as to the walls of the pelvis. 2. With parallel blades the compression of the head is produced only by the walls of the pelvis. 3. In cases in which the head is in the superior strait, even in an oblique diameter, a straight forceps can be successfully used on account of the absence of the pelvic curve. 4. With this instrument the progressive movements of the head are produced with much greater facility than with one which has the pelvic curve. 5. This instrument is especially useful for those who have not had much experience in the use of the forceps. 6. With this instrument it is easier to change the position of the head, and bring it into another diameter of the pelvis, than with others. 7. The blades can be joined together with great ease on account of the mobility of their articulation.

THE APPLICATION OF THE FORCEPS TO THE BREECH.—Truzzi ("Gaz. Med. Ital., Lombardia," Nos. 31-33, 1883; "Ann. de gynéc.," Jan., 1884) relates his experience in this method of using the forceps, a method which has been proscribed by most obstetricians, in a series of fourteen experiments upon the cadaver. The conclusions are as follow: 1. In a case in which the buttocks are wedged in the superior or middle portion of the pelvis, and the indication is for rapid extraction, the application of the forceps is preferable to traction in the groin with the finger, crotchet, or fillet, an operation which is likely to be attended with fracture of the femur or laceration of the soft parts in Scarpa's triangle. 2. Olivier's proposal to apply the forceps upon the thighs, and not upon the pelvis of the fetus, is plausible in theory, but not warrantable in practice. If his directions were carried out, the abdominal walls, and especially the region of the liver, might be compressed in a dangerous manner. 3. The application of the forceps upon the sides of the foetal pelvis is easier, more certain, and less perilous than Olivier's method. The soft tissues which cover the iliac bones form a suitable protection for them, and an unusual compressive force would be requisite to injure the bony structure. In all the author's experiments there was neither fracture of the iliac bones nor injury to the sacro-iliac or pubic articulation. 4. In order to obtain a good grip, the bite of the blades should reach the level of the iliac crest. The *point d'appui* should be taken at the iliac crest; the convexity of the foetal hips will adapt itself to the concavity of the blades of the forceps, and the abdominal viscera will escape injury. 5. Porro's forceps thus applied has an excellent grip, especially in the anterior presentations. In the intervals between the efforts at traction it is desirable to maintain a certain compressive force with the instrument, lest the resiliency of the iliac bones cause the instrument to lose its grip. 6. Porro's forceps will answer all the requirements for application to the breech. The author thinks that most of the forceps which are now in use are too large, and have departed far from the simple plan of the original instrument.

THE INTRA-PERITONEAL TREATMENT OF THE PÉRIE IN PORRO'S OPERATION.—Dr. V. Chalat ("Ann. de gynécologie," Aug., 1883) affirms that the primary Porro operation, in which the cervico-uterine stump is secured in the inferior angle of the abdominal wound, excels the ordinary Cæsarean operation in at least three respects: 1. In reducing primary hæmorrhage to the

minimum and in preventing secondary hæmorrhage. 2. In preventing the passage of the lochia into the peritoneal cavity. 3. In maintaining under control the inevitable exudate from the surface of the uterine segment. To these a fourth may be added, viz.: The prevention of subsequent conception. In place of removing the ovaries and tubes, the author suggests the firm ligation of the latter, as an effectual preventive against hæmorrhage at the monthly period, and this procedure is of advantage as well in the Cæsarean operation as in Porro's.

In the preparation of the stump, after the uterus and its contents have been removed, considerable care is required. The means for stopping hæmorrhage are very numerous, and will be adopted in accordance with individual preference. The stump may be constricted *en masse* or in two halves after its division, which latter method the author thinks preferable. The stump, being drawn to the lower angle of the abdominal wound, should be pierced by a long pin, or by two of them at right angles to each other, as a support for those parts which are to decompose and come away. Sutures or a clamp may be used in place of the pins. Disinfecting or caustic solutions must be applied to the decomposing portions as often as is necessary, and drainage of the abdominal cavity may be required as an additional safeguard against septicæmia. In spite of all precautions, the mortality from this method of treating the stump is not inconceivable, since fatal cases are not usually published. In case of recovery, the abdominal wound will require attention for a long time.

The intra-peritoneal treatment of the stump has connected with it the danger of hæmorrhage, peritonitis, and septicæmia, and therefore has not been extensively used. The detailed history of seven cases of supra-vaginal hysterectomy are given in which this method of treating the stump was adopted. The showing of results is not good—five deaths and two recoveries. Two other cases are added in which pregnancy was confined to one horn of the uterus, and in which that horn alone was removed, leaving conditions much more favorable for the treatment of the pedicle. Both patients recovered. Reviewing all the methods which have hitherto been devised for the intra-peritoneal treatment, the author concludes that they are either too difficult, too tedious, or too insecure to merit approval. He therefore proposes a new method, the practical success of which seems to him assured, since it will accomplish effective hæmostasis, afford suitable protection against those tissues and liquids which are capable of irritating and infecting the peritoneal cavity, require the least possible time, and can be executed easily, and in all places, with the ordinary instruments. This method is founded upon the use of the elastic ligature at the two angles of the pedicle, and upon the inversion of the stump, with a double row of sutures through the peritoneum. The steps are as follow: 1. A careful incision in the median line eighteen to twenty centimetres long, beginning at a point five centimetres below the umbilicus. It must be long enough to afford easy manipulation, and healing by first intention should be the desired end. 2. Müller's method of drawing out the uterus, the abdominal wall being pressed as close to it as possible, especially at the lips of the wound. 3. Incision of the uterus in the middle line of its anterior face, near the fundus, with a pointed bistoury. Extension of this incision with strong scissors, so as to form a reversed T, the vertical arm of which is fourteen centimetres and the horizontal five centimetres in length. Care must be taken that neither blood nor amniotic fluid enters the peritoneal cavity. 4. Extraction of the fœtus by the head or by the feet, according as one or the other presents; compression of the lower part of the body of the uterus and division of the funis between two ligatures. The placenta is not to be removed unless it is attached in the cervical zone.

5. Encircling the neck of the uterus with a disinfected rubber tube forty-five to fifty centimetres long, which is securely tied with a double knot. 6. Excision in succession of the uterus, the round ligaments, and the broad ligaments, just below the ovaries (the uterus being well drawn up), with a small amputating-knife. 7. Definitive hæmostasis. A disinfected rubber ligature, three millimetres thick and forty centimetres long, is carried by a strong needle through an opening one centimetre below the surface of the stump and one centimetre inward from its left angle, from the uterine cavity to the peritoneum. It is then carried around the stump and made to penetrate it again, from the peritoneum inward, at a point opposite the one at which it entered. The two ends are then forcibly drawn upon and securely fastened with whipcord tied in a double knot at the points where they enter the uterine tissue. By this arrangement the uterine, tubo-ovarian, and funicular arteries are completely under control. In the same manner the vessels upon the right side are secured. The surface of the stump is then to be touched with the Paquelin cautery or with a ten-per-cent. solution of chloride of zinc. Thus the dangers from sepsis and hæmorrhage are avoided, and the stump still retains its vitality by means of the circulation by anastomosis. 8. Removal of the tube which compressed the cervix, and stoppage of any hæmorrhage which may arise. The ends of the elastic ligature are then brought through the cervical canal into the vagina, and are allowed to hang out at the vulva. They can be removed in from eight to twelve days. 9. The stump is inverted for a distance of two and a half to three centimetres, which process necessarily turns the angles, with their elastic ligatures, into the cervical canal. The peritoneum is drawn over the stump thus doubled in thickness, deep sutures are passed through the entire mass, and the peritoneal edges are accurately apposed by superficial sutures. 10. Toilet of the peritoneum. Complete closure of the abdominal wound with a double row of carbolized-silk sutures. Irrigation of the cervico-vaginal canal. Antiseptic dressings.

PERITONITIS DURING PREGNANCY.—Dr. C. Mégrat (*Ibid.*, Nov., 1883) remarks that this affection may begin at any period of pregnancy. The evidences of its presence may be such as are met with in any ordinary attack (i. e., one uncomplicated with pregnancy), or they may be such as announce the commencement of premature labor. Should labor supervene, the severe symptoms of each condition will aggravate those of the other, and render the state of the patient truly dangerous. The diagnosis is an easy matter when the disease is isolated, but not when it is complicated with some other affection, especially of the abdominal viscera. The affection in a pregnant woman, even when no puerperal epidemic is present, is doubly grave, on account of the possible influence of the inflammation upon the pregnancy, and *vice versa*. The author discusses the prognosis under three heads: (1) with reference to the continuation of the pregnancy, (2) with reference to the survival of the child, (3) with reference to the life of the mother. If the disease is recognized at its commencement, and actively combated, it may usually be subdued, in the absence of epidemic influences, and abortion be prevented. If it becomes confirmed, however, especially if it becomes generalized, it will almost inevitably interrupt the pregnancy. It may be fatal to the fœtus by causing a premature birth. In the earlier months of pregnancy abortion from this cause is not so liable to occur as in the later ones. In many cases it does not seriously affect the mother's subsequent health. The treatment will depend upon the time in the attack when the patient is first seen, upon its intensity, its form, and its cause. In general, leeching and the use of opium will form the groundwork.

THE ETIOLOGY AND PATHOLOGY OF SPORADIC PUERPERAL SEPTICÆMIA.—Dr. W. Strange ("Brit. Med. Jour.," Dec. 22,

1883) still holds to his opinion as to the independence of puerperal fever of the contagion of the specific zymotic diseases, or, in other words, he thinks that it can not be propagated from the virus of scarlet fever, measles, small-pox, etc. His experience leads him to differ with most of the text-books as to their descriptions of puerperal fever, for he has found that the inflammatory element is *not* generally combined with the septicæmic process, and that the duration is usually from three to seven weeks. He has observed fatal results from three causes: as-thenia, pyæmic deposits, and thrombosis of the heart and pulmonary artery. Whether there is a specific organism which produces this disease he is not prepared to say, although he admits that micro-organisms abound in mucus from septicæmic puerperal women, and that the mucous membrane of such subjects is a favorable ground for their development. He is also convinced that the disease is not autogenetic—that is, does not begin upon the body of the patient, but does begin with some cause of infection from without.

Miscellany.

THERAPEUTICAL NOTES.—*The Administration of Phosphorus.*—M. Pierre Vigier concludes an interesting communication on the pharmacology of phosphorus ("Gazette hebdomadaire de médecine et de chirurgie," February 22, 1884) with the statement that its administration should be limited to the two following forms: 1. The phosphide of zinc, in pills of 8 milligrammes, corresponding to 1 milligramme of phosphorus, of which from two to eight may be taken daily. 2. Phosphorated oil, one per cent., in capsules of 10 centigrammes each, containing 1 milligramme of phosphorus. These capsules or "pearls," he remarks, are to be had of good quality in the shops.

Bichromate of Potassium.—According to the "Journal des sciences médicales de Lille" (quoted in the "Progrès médical"), Dr. Güntz, of Dresden, and Professor Vulpian have lately rescued this agent from oblivion. The former recommends it as an excellent antisyphilitic, and, moreover, as a preventive of syphilis, used in the form of an aerated solution (*eau chromée gazeuse*), as follows:

Bichromate of potassium.....	0.03;
Nitrate of potassium.....	0.10;
Nitrate of sodium.....	0.10;
Chloride of sodium.....	0.20;
Water.....	600.00.

Dissolve the salts in the water, and charge highly with carbonic acid.

M. Vulpian speaks highly of the effects of the drug in certain cases of dyspepsia, especially those in which, probably from a catarrhal or an arthritic affection, the symptoms resemble those that mark the onset of epithelioma of the stomach. On account of its disagreeable taste, he uses it in the form of pills, according to the following formula:

Bichromate of potassium.....	0.50;
Extract of valerian.....	5.00.

Divide into fifty pills, each of which will contain 1 centigramme of the salt. The amount taken daily may vary from 2 to 10 centigrammes. For external use, the bichromate is employed as a caustic, either in solution or in the form of an ointment, for venereal sores, but more commonly for warts. The ointment may be made in the proportion of one part of the salt to twenty of lard. In adults, it is better to cauterize a wart directly with a crystal of the bichromate; its action is somewhat slow, but it is surer than that of lapis infernalis, and it is less disagreeable and decidedly less dangerous than that of nitric acid.

A BILL TO PREVENT CONTESTED-WILL CASES.—There has been presented to the Legislature of this State a bill calculated in some measure to do away with the scandalous scenes often enacted in the surrogates' courts on the probate of wills. It has been a frequent custom, when a

rich man dies, for a host of contestants to rise up and attempt to prove the mental unsoundness of the testator, or his subjection to the improper influences of those about him. The danger that this will occur has no doubt often prevented persons from making wills, the preference being for an equal distribution, under the laws of the State, to the raking up of unpleasant secrets. In addition to this, the prospect that the estate would be rapidly depleted by ungrounded contests has led many persons in this State to look with much interest to Michigan, where the experiment has been tried for some years of allowing a man to present his will to the surrogate in his lifetime, and cite all persons who could have an interest in his estate to appear and object to his mental soundness or to the improper influences exerted over him. If nothing substantial could be alleged on these points, the surrogate was to make a decree declaring the person able to make a valid will, and this decree could not be attacked after the person's death. This law has worked so well in Michigan that it is said that will contests are almost unknown there. The following are the provisions of the bill now before our Legislature:

SECTION 1. To any will heretofore or hereafter executed the testator may make and annex his petition, to be sworn to before and presented to the surrogate for the county where the testator resided, or to any court or officer having jurisdiction to take probate of wills, asking that such will be admitted and established as his last will and testament.

SEC. 2. Every such petition shall contain averments that such will was duly executed by the petitioner without fear, fraud, importunity, or undue influence, and with a full knowledge of its contents, and that the testator is of sound mind and memory and full testamentary capacity; and shall state the name and address of every person who at the time of making and filing the same would be interested in the estate of the maker of such will as heir, if such maker should at the making of such petition become deceased, and may also contain the names and addresses of any other persons whom such testator may desire to make parties to such proceedings.

SEC. 3. Such court shall thereupon, upon request of such testator, appoint a time for the hearing of such petition, and issue citations to the parties named in such petition, and direct published notice of such hearing, and have such hearing, after proof of service of citations and of publication of notice, in the manner, as near as practicable, as is required for the probate of wills.

SEC. 4. If any person named in such petition shall be a minor, or otherwise under disability, a guardian *ad litem* shall be appointed by such judge to represent such person. On such hearing, such court shall examine into the matters alleged in such petition and into the testamentary capacity of such testator, and examine witnesses in relation thereto; and if it shall appear that the allegations of such petition are true, and that such testator was of sound mind and memory and full testamentary capacity, such judge shall make decree thereon, and shall cause a copy of such decree to be attached to said will, certified under the seal of said court, decreeing that the testator, at the making of such will and such petition, was possessed of sound mind and memory and full testamentary capacity, and that said will was executed without fear, fraud, importunity, or undue influence, which decree shall have the same effect as if made by said court after the death of testator on the probate of such will; and such will, having been so established, shall not be set aside or impeached on the ground of insanity or want of testamentary capacity on the part of the testator, or that the same was executed through fear, fraud, importunity, or undue influence.

SEC. 5. Appeals shall lie in the same manner as from probate of wills.

SEC. 6. Nothing in this act contained shall be construed to prevent the revocation of such will, or alteration, or other change thereof, as in ordinary wills.

CASTOR-OIL AND SCHOOL DISCIPLINE.—According to the "British Medical Journal," castor-oil is employed as a means of punishment in the West Highland School of Lochgilhead, Scotland. Breaches of school discipline are treated by "doses of castor-oil" administered, not in the usually prescribed quantity, but by a draught from the bottle. Whatever laxity exists in that school is certainly not on the part of the teachers.

Original Communications.

THE EFFECTS OF ADDUCTION AND ABDUCTION ON THE LENGTH OF THE LIMB IN FRACTURES OF THE NECK OF THE FEMUR.*

By WILLIAM S. HALSTED, M. D.,

SURGEON TO BELLEVUE HOSPITAL; ASSISTANT SURGEON TO THE ROOSEVELT HOSPITAL.

AGREED though we all are that the pelvis should be horizontal when measurements to determine the relative lengths of the limbs are made from the anterior superior spinous processes of the ilia to the malleoli, very few indeed are familiar with the facts which make it necessary. The reply, that an obliquity of the pelvis causes an apparent difference in the relative lengths of the lower extremities, is true, but does not explain. It implies, to be sure, that one leg is adducted and the other adducted, and yet this of itself might be possible without leading to error by measurement.

FIG. 1.

Thus, in Fig. 1, let rs and ls represent the anterior superior spines of the ilia, ra and la the right and left acetabula, and rm and lm the right and left malleoli (external or internal). If, now, the pelvis be rotated on an antero-posterior axis passing through the left acetabulum, la , the right malleolus, rm , becomes raised to rm' ; the right leg is adducted and apparently shortened, and the left leg is abducted. Nevertheless, the line $rs'rm' = ls'lm'$, just as before the line $rsrm = ls lm$ did, proving that, if our diagram be correct, measurements from spines to malleoli can determine accurately the relative lengths of the limbs, notwithstanding an obliquity of the pelvis.

But we know, from observation of the earlier stages of hip-joint disease, that, if the diseased limb be adducted and apparently shortened, it will measure longer than the healthy limb; and, conversely, that, if the diseased limb be abducted and apparently lengthened, it will be shorter by measurement than the sound limb.

* Read before the Medical Society of the County of New York, February 25, 1884.

This could not be the case if the spine, acetabulum, and malleolus of one side occupied the same perpendicular line as represented in Fig. 1. We look, then, to the skeleton for an explanation, and find that the spines are farther apart than the acetabula are. In Fig. 2 this is illustrated. Here,

FIG. 2.

too, the line $rsrm = ls lm$, provided the line $rs'ls$ be parallel to the line $rm lm$, or, in other words, provided the pelvis be horizontal. When, however, it is rotated, as before, about an antero-posterior axis through the left acetabulum, la , the line $rs'rm'$ measures more than the line $ls'lm$. Because, then, of the tilting of the pelvis, the adducted left leg measures less than the adducted right leg. Furthermore, the adducted left leg measures less than it did when straight, and the adducted right leg more than it did when straight, as a glance at Fig. 3 will suffice to show.

FIG. 3.

In this figure the obtuse-angled triangle $rsra$ has, for the sake of clearness, been separated from Fig. 2, and now it is perfectly evident that when the angle $rsra$ is made less obtuse, as it would be by adducting the leg ra , the line $rsrm'$ measures less than $rsrm$; that is to say, the leg is shortened by measurement from spine to malleolus, and that adducting the leg until the spine rs , the acetabulum ra , and the malleolus rm occupy the same straight line, $rsra rm'$, lengthens the leg by measurement. For in

the one instance (in abduction) we measure one side $rs\ rm$ ", and in the other (in adduction) $rs\ ra + ra\ rm$ of the triangle. A. Nélaton recognized this triangle, and pictures it in his "Éléments de pathologie chirurgicale," tome ii, p. 833.

And, to quote Barwell,* Gädchens, in 1836, called attention to the fact "that when the ilium inclines to one side, its crista must approach the trochanter of the femur; thus, though the whole thigh may sink and appear longer, the measurement between any point of the crista ilii and of the thigh must be shorter than the other limb." I do not understand why he did not (if indeed he did not) draw the complementary conclusion that adduction, up to the extent to which we have already referred, must make the limb measure longer, unless, as is highly improbable, he believed that the spine, acetabulum, and malleolus were normally on the same perpendicular, in which case adduction would make the limb measure just so much shorter as abduction through the same number of degrees would. I say "highly improbable," because Gädchens speaks of a sinking, apparent lengthening, and measured shortening of the abducted thigh. Now, apparent lengthening with measured shortening of the abducted limb would, if the three points above mentioned were on the same perpendicular, only be possible provided the limbs were not approximated; and if Gädchens compared by measurement divergent limbs, irrespective of the angles which they formed with the pelvis, his results could not have been sufficiently constant to enable him to arrive at the conclusions which he did. To confirm, experimentally, that adduction produces lengthening by measurement from spine to malleolus, the writer has driven nails into cadavers at the points mentioned, and found that adduction may give measured lengthening from 2 to 8 mm., and abduction measured shortening from 2 to 4 cm, or thereabouts, in different cases.

Clinically, too, in fractures of the neck of the femur, adduction and abduction probably frequently occur, and to a considerable degree. To recognize these as factors in the deformity is essential for even an approximate estimation of the amount of real as distinguished from measured and apparent shortening. Its recognition is further of importance from the treatment standpoint.

If in fracture of the neck of the femur there be neither abduction nor adduction, the pelvis will be horizontal when the legs are parallel. In such a case the apparent shortening, real shortening, and measured shortening would be practically equal. Thus, in Fig. 4, the apparent shortening = $lm\ y$, the real shortening = $rt\ x$, and the measured shortening = $ls\ lm - rs\ rm$.

When, however, adduction is an element in the deformity, there will be apparent shortening, almost invariably real shortening, and possibly measured lengthening, provided the adduction be considerable and the real shortening not excessive.

This measured lengthening I have once observed in my wards at Bellevue Hospital, and had the opportunity to confirm the diagnosis at the autopsy. The case was reported recently at the surgical society, and the specimen of the fracture, which was intra-capsular, presented.

It is in this particular variety of fracture, when associated with adduction, that the diagnosis might be difficult,

FIG. 4.

if not impossible, unless the special features of the case were recognized.

Lisfranc and Lallemand have each observed a case of fracture of the neck of the femur in which the broken limb was the longer.

Senn,* referring to these cases, says that "it is impossible to conceive in what manner the fracture could add to the length of the limb."

He was evidently unacquainted with the points upon which the writer is dwelling.

The recognition of the adduction is furthermore of importance because, if the limb be allowed to remain in this position, the patient will surely limp when he walks, notwithstanding the fact that there may be measured lengthening and very little real shortening.

FIG. 5.

In Fig. 5 is outlined a fracture of the neck of the right femur, with adduction. The apparent shortening, $lm\ y$, is excessive, although the real shortening, $rt\ x$, is inconsiderable. The lengthening by measurement equals $rs\ rm - ls\ lm$.

Figs. 6 and 7 represent fractures of the neck of the right femur, with abduction. In 6 there is little abduction and

great real shortening, and, consequently, apparent shortening. In 7, much abduction, little real shortening, and hence ap-

parent lengthening. Although the measured shortening is greater in 7 (the case of apparent lengthening) than in 6, the

FIG. 7.—FRACTURE OF THE NECK OF THE RIGHT FEMUR, WITH ABDUCTION.

$rm\ y$, apparent lengthening; $rt\ x$, real shortening; $ls\ lm - rs\ rm$, measured shortening.

patient in the case of apparent shortening (Fig. 6) would limp, and in the other might not. Apparent shortening, consequently, is undesirable, and should be overcome if possible. Thus it becomes evident that statistical tables designed to show how much measured shortening may exist without causing a limp, and how little measured shortening occurs in many cases of fractures of the neck of the femur, are worthless unless the adduction and abduction which may have been present were recognized.

König* believes that the amount of apparent lengthening or shortening equals the difference in level between the right and left anterior superior spines of the ilia. That this is not strictly accurate is shown in Fig. 8; for the line $rs\ z$, which represents the difference in the level of the spines, is longer than the line $y\ lm$, which represents the apparent

lengthening. The line $ra\ x = y\ lm$, but, unfortunately, can not be accurately determined on the living subject. Bryant's line, for obvious reasons, is only to be relied upon when the pelvis is straight.

FIG. 8.

To determine, then, approximately, the amount of real shortening, it is best that the pelvis should be horizontal. For the sake of accuracy, a Volkmann's coxanyklometer, or something equivalent, may be employed.

Or, if it be difficult to straighten the pelvis, one might make use of a procedure recommended by Giraud-Teulon. This consists in a geometrical device for determining the distance of either one of the condyles of the femur from the center of the cotyloid cavity. The middle point of a line drawn from the anterior superior spine of the ilium to the tuberosity of the ischium corresponds quite closely to the center of the acetabulum. If, then, a triangle be formed by lines drawn between one of the condyles of the femur, the anterior superior spine of the ilium, and the tuberosity of the ischium, the length of a line let fall from the condyle selected (the apex of the triangle) to the middle of the base line (that drawn from spine to tuberosity) equals the distance from said condyle to the center of the cotyloid cavity, whatever may be the position of the pelvis or femur.

47 EAST TWENTY-FIFTH STREET.

A COMPARISON OF TOTAL AND MANIFEST HYPERMETROPIA, AS DETERMINED BY THE PRISOPTOMETER, WITH AND WITHOUT THE USE OF MYDRIATICS.

By H. CULBERTSON, M. D.,
ASSISTANT SURGEON, UNITED STATES ARMY (RETIRED).

THE "prisoptometer" is an instrument invented by the writer to determine ametropia, through the aid of a prism of glass. A description of it may be found in the "Cincinnati Lancet and Clinic," January 20, 1883, and in the

* "Lehrbuch der speciellen Chirurgie," vol. iii, p. 267.

"Journal of the American Medical Association," January 5, 1884. It should be stated that its results are accurate, and that its application is simple.

The object of this paper is to decide, first, what is the degree of *manifest* hyperopia as shown by the instrument without the aid of mydriatics, and, secondly, to determine by it the total hyperopia after the use of agents which paralyze the ciliary muscle.

0° It should be stated that the scale of the "prismometer" is represented as follows.
90° — 9 It runs from the vertical 0° to 90° on either side, and to the horizontal line.

By reference to the table it will be seen that hyperopic astigmatism, as well as the spherical hyperopia, has been included in the calculations.

The following is a tabulated statement of the cases:

TABLE.

NAME.	No. of case.	Age.	Right or left eye.	Mydriatic used.	Formula for dioptics of hypermetropia total under mydriatic.	Formula for dioptics of hypermetropia manifest without mydriatic. Total.							67.50	39.75	58.88			

Each eye examined, in the same individual, is regarded as a case.

The least degree of *manifest* hyperopia observed in the table is in Case 36, in a patient aged 34 years—viz., 25 per cent. It follows, in this example, that there is shown the greatest increase of *total* hyperopia, 75 per cent.

In Cases 1, 2, 3, 6, 7, 8, 9, 16, 17, 27, 32, 41, 42, 43, 44, and 45 (= 16 cases) the *manifest* hyperopia, without the aid of mydriatics, was equal to 100 per cent. In some of these examples the degree of hyperopia was high, in several very low, but in most cases it was medium.

In the following cases no manifest hyperopia was observed without the use of mydriatics: 4, 5, 10, 11, 19, 20, 23, 24, 25, 26, 28, 29, 31, 34, 35, and 37. In each of these 16 cases the *total* hyperopia was of low degree.

If the sum of the dioptics, in the 45 cases, of *total* and *manifest* hyperopia be estimated *before* and *after* the employment of mydriatics, there will be found:

67.50 dioptics of hyperopia total.

39.75 " " manifesta, and hence
27.75 " " increase, as an average for

all the examples of the table = 41·12 per cent., and due to the influence of mydriatics.

The proportion of *manifest* to *total* hyperopia, deduced from the 67·50 *total* and the 39·75 *manifest*, as above, for all the cases, is 58·88 per cent. *manifest*, which is an average result for all the members of the table, and shown without the use of mydriatics.

If the cases of the table be excluded above the age of 45 years, then, in the 38 cases remaining, the sum of *total* and *manifest* hyperopia will be:

54·50 dioptrics of hyperopia *total*.

28·25 " " *manifesta*,

26·25 " " increase = 48·16 per cent., and due to the agency of mydriatics.

From these figures 54·50 and 28·25, dioptrics, the per cent. of *manifest* hyperopia, up to the age of 45 years, and without the aid of mydriatics, is 51·84.

If the table be classified in periods of five years, and the sum, each, of *total* and *manifest* hyperopia be computed for these several classes, the following record will be shown:

AGE—YEARS.	H. total D.	H. manifest D.	Hm. per cent.
11 to 15.....	13·25	11·75	88·67
16 to 20.....	7·75	5·75	74·19
21 to 25.....	14·75	6·75	45·75
26 to 30.....	10·00	2·00	20·00
31 to 35.....	8·75	2·00	22·86
36 to 40.....	No cases.		
41 to 45.....	1·50	1·00	66·66
Over 45.....	11·50	10·50	93·30

According to these data, children from 11 to 15 years of age develop more *manifest* hyperopia than persons aged from 16 to 20, and from 21 to 35 years *this* diminishes to 22·86 per cent., and that after 45 years the *manifest* hyperopia increases to 91·30 per cent. These percentages are based on the sum total of hyperopia for each class.

Age, therefore, according to these results, is associated with a gradual diminution of *manifest* hyperopia from 11 to 44 years, after which age *this* increases and is nearly equal to the *total* hyperopia.

This does not correspond with Hirschberg's conclusions, as reported by Louis Daniel (Berlin), (see "Ophthalmic Review," October, 1883), who finds that from 26 to 35 years Hm. = 75 per cent., whereas the foregoing table reveals *manifest* hyperopia equal to (within the same age-period) 42·86 per cent. only. From 36 to 45 years the same observer found 80 per cent. of Hm., while the table for this age-period reveals hyperopia *manifesta* = 89·52 per cent. Perhaps a portion of this discrepancy is due to the fact that there is but one case in the table aged 45 years. Another cause of the disagreement cited may be that, in all this gentleman's cases mentioned, the hyperopia *total* was determined by direct ophthalmoscopic examination, and hence the full amount of hyperopia may not have been found, at least not so great a degree of *this* as would have been discovered had mydriatics been employed, especially duboisine.

On the other hand, it is probable that the degree of *manifest* hyperopia developed through the instrument is not erroneous, because its records correspond so nearly in the

age-period, 6 to 25 years, with the Hm. found by Hirschberg; and, moreover, its results are practically the same as those detected in the cases of the table in distant vision with the test types of Snellen. Further, it should be stated that, in testing with this instrument, the eye not under examination is closed, the "object-plate" is placed at twenty feet from the observer, and, consequently, parallel rays of light are employed during the test, all of which favor the development of *manifest* hyperopia.

It should be added, too, that an instrument which is capable of recording 88·67 per cent. of Hm. in those aged from 11 to 15 years can not be defective in its operation in those of greater age.

The cases given in the table are all uncomplicated.

The average number of *dioptrics* for the 45 cases is 1·5 H. total, and 0·88 Hm.; so that the low average degree of hyperopia can not be the cause of the diminution of the Hm. between the ages from 30 to 40 years.

The decrease in the power of the ciliary muscle, due to advancing age up to 45 years, should increase the *manifest* hyperopia; but the table reveals that, from 11 to 28 years, the Hm. steadily diminished to 20·00 per cent. of the total H. On the other hand, the total H. gradually increased to 80·00 per cent. in the same age-class.

There has been no creation of hypermetropia, which has simply diminished as *manifest* and increased as latent hyperopia, and the reduction of the former has decreased as the power of the ciliary muscle is weakened, as the age approaches 45 years.

It is quite evident, too, that, while using the instrument to detect low degrees of hyperopia, the ciliary muscle does not relax, but, by its *positive contraction*, maintains and overcomes the manifestation of a portion of the hyperopia, so that only when this muscle is paralyzed can the total hyperopia be obtained, up to 45 years of age.

Before and including the latter age, the table reveals in these cases that there remained enough, or an excess, of *ciliary power* to maintain the diminishing hyperopia *manifesta* present after the total H. had been deducted from the dioptrics of ciliary power present in each case, according to the age. This is shown in the following table:

NO. OF CASE.	Age, years.	Ciliary power for the age, in dioptrics.	Dioptrics of total H.	Dioptrics, excess of ciliary power.	Dioptrics of Hm.
2	12	13·00	5·00	D8·00	D5·00
3	12	13·00	6·00	D7·00	D6·00
4	15	12·00	0·75	11·25	D0·00
8	17	9·00	2·25	6·50	D2·50
18	24	8·50	6·50	2·00	D1·75
33	33	5·50	1·25	3·25	D0·75
38	45	3·50	1·50	2·00	D1·00

After 45 years of age the records of the table suggest the presence of other influences in the eye, which determine an increase of the Hm. as well as the diminution of the ciliary power.

CONCLUSIONS.

1. That through this instrument from 50·00 to 100·00 per cent. of *manifest* hyperopia can be detected.
2. That with it there is shown, from 10 to 45 years of age, a gradual diminution of manifest hyperopia.

3. That through its aid high degrees of hyperopia will reveal a greater quantum of manifest hyperopia.

4. That its results denote that low as well as high grades of hypermetropia, both *manifest* and *total*, may be detected by the instrument; but that mydriatics will be required to determine positively the *total* hyperopia.

Perhaps it should be stated that this instrument is manufactured by Messrs. George Tiemann & Co., 67 Chat-ham Street, New York.

ZANESVILLE, OHIO, February 5, 1884.

THE PREVENTION OF PUERPERAL INFECTION.

A STUDY OF ANTISEPTIC PRACTICE IN THE MATERNITY HOSPITALS OF PARIS, PRAGUE, BERLIN, PARMA, GLAS-GOW, COPENHAGEN, AND NEW YORK.

By SIMON BARUCH, M.D.,

GYNÆCOLOGIST TO THE NORTHEASTERN DISPENSARY.

IN the "New York Medical Journal" of March 1, 1884, Dr. H. J. Garrigues contributes a paper in which he inveighs with some warmth against certain views which I had expressed in a recent paper ("Medical Record," February 16, 1884) on the subject of "Prophylactic Vaginal Injections after Normal Labor."

I hail with pleasure any method which will render the puerperal period more comfortable and more free from complication, and for this reason I have indorsed Dr. Garrigues's method, of the success of which in the New York Maternity Hospital he has reason to be proud. But I took issue with Dr. Garrigues only in regard to the *modus operandi*. I hold that the advantage of his method arises not from the antiseptic napkin which he has introduced, nor from the substitution of bichloride-of-mercury injections during labor, which had been already used in Germany and France, but from the scrupulous cleanliness, in which he is a worthy follower of his countryman Stadfeldt, and chiefly from the abolition of the prophylactic injections after normal labor, which I have demonstrated as useless and dangerous. In other words, Dr. Garrigues is more successful than his predecessors, because he leaves the utero-vaginal tract at rest as well as the parturient woman.

Like all other innovators, Dr. Garrigues feels a pardonable love for his bantling, and defends it with that earnestness which characterizes all his work. But his parental jealousy so blinds him that he strikes against the only (published) defender of his method, and accuses him of "unwarranted conclusions from his paper" and of insinuations upon his "judgment, discrimination, and bias."

I will not reply to his strictures, except to say that I have quoted verbatim from his PUBLISHED paper. Of his unpublished practice I knew nothing. I entertain too high a regard for Dr. Garrigues, as an honest investigator and earnest worker in his chosen field, to attempt a merely polemic contest with him, especially as such a discussion would be of no value or interest to the readers of this journal. I can not, however, allow his allusions to and implied defense of the value of prophylactic vaginal injections after normal labor to pass unchallenged.

Dr. Garrigues says in his last paper: "The hue and cry recently raised against vaginal injections exaggerates, in my opinion, very much the danger of this mode of treatment."

As I have been chiefly instrumental in raising this "hue and cry," I may be permitted to offer some new and very striking evidence to sustain my position. In my papers, and in my remarks during the discussion of this subject, I have again and again emphasized the inutility and harmfulness of prophylactic injections. It is true, they came in, as Dr. Garrigues says, with the improved antiseptic method, but it is also true that they have been abandoned, just as the intra-uterine injections for prophylaxis have been abandoned; more slowly, perhaps, than the latter, because their inutility and harmfulness were not so pronounced as those of the former. When intra-uterine injections for prophylaxis were introduced in Germany by Fritsch, a great improvement was at once noticed in the morbidity and mortality of childbed. But very soon their capacity for harm was discovered, and, all along the line where they had been enthusiastically praised, the tocsin of danger sounded. They offered an improvement upon former methods, but they proved dangerous. Vaginal injections were retained, but these are now fast meeting the fate of intra-uterine prophylactic injections.

In a recent work* the subject of antisepsis in midwifery practice has received a very complete and exhaustive treatment, and I avail myself of information obtained from so authoritative a source to fortify a position which I have assumed only after careful observation at the bedside. The arguments and statistics which I have up to this time brought to bear in opposition to prophylactic vaginal injections were the offspring of investigations made since my clinical experience forced me to abandon them. And so it is with the material I now propose to use, some of which came into my possession only a few days ago.

Dr. Paul Bar is chef de clinique adjoint d'accouchements under the apostle of obstetric antisepsis in France, Dr. Tarnier, who was the first to recommend the now popular bichloride-of-mercury solution in midwifery practice at the International Medical Congress in 1876. Dr. Bar presents a *résumé* of all that is known upon the subject, and sums† up his views under the first head, "Treatment after Natural Delivery," with which we are now chiefly concerned, as follows: "We need not repeat all the general precautions which should be taken—disinfection of the medical and auxiliary *personnel*, rooms, etc. We have sufficiently insisted upon these points, etc. There is one chief rule from which we should not depart: *we should avoid doing too much; that which is useless is dangerous* [*italics mine*]."

"Immediately after the termination of labor the external organs of generation should be carefully washed with an antiseptic solution (corrosive sublimate, 1 to 2,000), not the slightest clot of blood being allowed to remain upon the hairs which cover the vulva, etc.

"After this, a dressing should be applied with the greatest care to the vulva, in accordance with the antiseptic method.

* "Des méthodes antiseptiques en obstétrique," par le Dr. Paul Bar. Paris: Alex. Coccoz, 1883.

† P. 201.

"A large strip of carbolized, salicylated, or benzoated gauze, doubled in many folds, covered by a strip of Macintosh, is now applied to the vulva. Carbolized gauze is very irritating, and, after a few days, a very painful eruption is observed upon the neighboring parts. We may in this case have recourse to compresses of gauze saturated with a solution of corrosive sublimate, 1 to 2,000.

"Salicylated and carbolized wadding, etc., render great service, and may be substituted for the gauze with advantage. Oakum is very much used as a dressing by Freund. Whatever be the antiseptic selected, it should be renewed three or four times a day, more frequently if the lochial flow be very abundant."

He proceeds to state the teachings of Fritsch on the necessity for vaginal injections after labor, which he says "a jouti d'une certaine faveur." Continuing, he says: "*The vaginal injections in the cases now under consideration have been experimented with in the Maternité; to-day they are no longer resorted to; they fatigue the women; they are really only employed when the lochia are retained in the vagina, or when they are 'odorantes.'* If we should resort to them in all cases without distinction, they may overreach our end and become harmful, because, as Brünneke has shown, there is risk of introducing into the vagina an improper instrument, and of producing accidents.

"To sum up (p. 208), we should content ourselves with applying dressings to the vulva. They suffice to protect the sick against all accidents."

Thus, it will be seen, the author's treatment, culled from the most successful methods, furnishes not only a demonstration of the correctness of my own position regarding prophylactic vaginal injections, but I quote it also in order to give, from an authoritative source, that support to Dr. Garrigues's antiseptic method which it has not received in this country.

The details of various methods of obstetrical antiseptics and their result in some large institutions in Europe may not be devoid of interest. I will quote them briefly, in order to show that "the hue and cry recently raised against vaginal injections" is well founded upon practical evidence.

In the Paris Maternité (p. 101) the antiseptic plan has been for some time the same as that practiced by Dr. Garrigues with so much success. In the "Pavillon Tarnier" there were, from 1876 to 1879, inclusive, 788 deliveries with six deaths, only eleven cases of puerperal infection having been observed. From 1880 to June 4, 1883, inclusive, there were 692 deliveries, with *not a single death*, and only six cases traceable to puerperal infection.

In Prague the procedure of Breisky, who had *not a single death* in 1882 from puerperal infection, is worthy of note, because it emphasizes what I have said on the subject of cleanliness being more important than antiseptics, and it also affirms the inutility of injections during ordinary labor and during the puerperal period, unless specially indicated. In a letter of Dr. Fischel, who is Breisky's assistant, to Dr. Paul Bar (p. 111), Fischel says: "We never forget the soap, which we regard as more important than carbolic acid. Before the touch, the fingers are carefully washed with soap and carbolized water by means of a large brush;

the nails, always cut very short, are scoured with the greatest care. The disinfection of the attending *personnel* is urged to a very high degree. We do not remember having seen in this hospital a midwife presenting the slightest spot on her hands. For the touch, a five-per-cent. carbolized vaseline is used. *During the labor, vaginal injections are not practiced.* In Breisky's service this procedure was resorted to about ten times only, when the vaginal secretion was very abundant or decidedly purulent. In simple leucorrhœa the vaginal douche is superfluous. *But all that is superfluous must be avoided*, for we do not know but that it may be dangerous. If the number of students examining be considerable, vaginal injections are given during labor. If the labor has been normal, an irrigation with a two-per-cent. carbolized or ten-per-cent. chlorinated solution is made level with the vulva. Any small fissures or contused wounds of the vulva are covered with iodoform. Sutures are used at once if necessary. After every operation a vaginal injection is made with a five-per-cent. carbolized solution. If the introduction of the hand into the uterus had been required, an intra-uterine injection is made; but never is the syringe resorted to; the irrigation is always used for this purpose, with a five-per-cent. carbolized solution, of which two to six litres are passed into the uterine cavity. After the birth of a macerated fœtus, or if there be fever present during labor, these injections are also resorted to. It is unnecessary to state that after every operation—forceps, version, etc.—a vaginal injection is always made. In this service only one third of the cases require vaginal injections; *they are resorted to only where there are precise indications*, over-secretion of lochia, putrid lochia, with or without fever, purulent vaginitis, etc.

"In these exceptional cases small iodoform pencils are introduced. All dressings are made for the purpose of protecting the sick; the best disinfection consists in avoiding infection. Rarely are intra-uterine injections resorted to, and they are always administered by the physician.

"In cases of purulent infection we are generally contented with practicing vaginal injections; ulcerations of the vagina, vulva, or cervix uteri are treated by a saturated solution of permanganate of potash or strong tincture of iodine. Let us add that in all vaginal injections glass tubes are used. In the service of Professor Weber the method employed is nearly the same, except that he uses tampons of chlorinated wadding as a direct application to the vulva."

Now, what has been the result of this rational antiseptics, which avoids all unnecessary elements? In the Prague Maternity the mortality was as follows in late years: In 1879 it was 0.36 per cent., in 1880 it was 0.46 per cent., in 1882 it was 0.56 per cent., in the entire hospital. In Breisky's division there was *not a single death*, and there were only ten cases of puerperal infection in 1882.

In Copenhagen the mortality has been wonderfully small, both in hospital and private practice, since 1876. In 1876 it was 0.6 per cent., in 1877 it was 0.7 per cent., in 1878 it was 0.8 per cent., in 1879 it was 0.6 per cent., in 1880 it was 0.26 per cent., in 1881 it was 0.5 per cent., in the Maternity, and, what is remarkable, the mortality was even smaller in private practice, except in 1880 and 1881. Let

us see how we can account for this small mortality. The antiseptic method adopted by Stadfeldt is as follows: "Every female is received in a special room, where she is examined by the chief midwife, one of the physicians, and one or two pupils. A two-per-cent. vaginal injection is made with the greatest care. After every examination the hands are minutely washed with soap and brush, and disinfected with a 2·5-per-cent. carbolized solution. The fingers are lubricated with a ten-per-cent. carbolized oil, or ten-per-cent. salicylic ointment. The woman is transferred to the accouchement service, which is distinct in all respects from the lying-in service. During the labor a vaginal injection is given every two to ten hours. When the head appears, a cloud of carbolized solution is projected against the generative organs. After delivery a vaginal injection is given. Intra-uterine injections are reserved for the cases in which an operation has been done, or when the membranes have been retained. In perineal rupture immediate suture is made, and the wound is dressed with a tampon saturated with ten-per-cent. carbolized oil. We never resort to sponges in this hospital. About an hour after delivery the woman is transferred to the lying-in service.

"If everything is normal, the external organs are washed two or three times a day with carbolized water. *Vaginal injections are reserved for cases in which the lochia are fetid, or analogous cases.* Intra-uterine injections are not resorted to except in cases in which retained placental debris are putrefying. So soon as signs of puerperal infection manifest themselves in a woman, she is at once transferred to the hospital, and the midwife is carefully disinfected."

Bar remarks (p. 117) that the antiseptic method is also enforced with great care among the midwives and in private practice in Copenhagen.

For the purpose of comparison, I will now present some statistical evidence which must sustain my "hue and cry against vaginal injections."

From the Charité at Berlin, Hartmann* reports for 1878, 908 deliveries, with 23 deaths, being 2·5 per cent. The antiseptic method adopted in this division is as follows: The women are isolated; every woman receives a bath and a vaginal injection before labor. *Twice a day she receives, after labor, two vaginal injections.* Uterine injections are resorted to only for cases of puerperal infection.

In the Maternity Hospital at Parma† all antiseptic precautions are taken: "the nails are scrupulously cleaned, the hands are washed with a solution of permanganate of potassium, glass tubes are used for the *vaginal injections*, etc. The average mortality from 1876 to 1880 is reported 3·42 per cent."

In the Charité, at Berlin, since 1879, Gusserow orders disinfection of physicians, midwives, nurses, students; careful disinfection and cleansing of the bed, the parturient woman, and all utensils are watchfully effected. At the beginning of labor a scrupulous cleansing of the genital organs and a vaginal injection with weak carbolized solution, and a bath, if possible, are given. If labor is protracted or examinations are numerous, the vaginal douche is repeated, also

immediately after labor. After all manipulations within the uterus, and after all operations, the uterus is irrigated with a 3-to-5-per-cent. carbolized solution, also after the birth of a macerated fetus, etc. "*During childbed, I order in most cases vaginal injections twice a day, in order to remove the lochial secretion.*" "I acknowledge here, at the risk of saying something heretical, that I regard exemplary cleanliness as the principal thing, and disinfection only as a valuable auxiliary which is not to be omitted."

The result in the Charité, from 1879 to 1881, inclusive, under Gusserow's administration, was an average mortality of 1·5 per cent.

For 1882, Sommerbrodt reports from Gusserow's wards a mortality of 1·6 per cent. ("Charité Annalen," 1882).

From the Glasgow Maternity, Dr. Sloan communicates that the antiseptic method, which had not been thorough until within two years, is as follows: The pregnant females are well nourished and live as much as possible in the open air. Every woman in labor takes a bath before admission into the accouchement ward. Before each examination the physicians wash their hands and nails with carbolized water and soap. Once the delivery is accomplished, every woman receives an intra-uterine injection of carbolized water, during which operation all clots are pressed out of the uterus. In a few hours she is transferred on a litter to the lying-in-ward.

Evening and morning, during her sojourn in the hospital, every woman who has been delivered receives a vaginal injection of carbolized water; on the sixth day after delivery a pessary of eucalyptus is placed within the os uteri; immediately after each injection the linen used in the dressings is disinfected by sulphur vapor in a special disinfecting chamber. The alternation of wards after disinfection by sulphur is practiced when possible.

There were 383 deliveries and 25 operations, with 5 deaths, from 1881 to May, 1883.

In order to bring out the more striking points of these statistics, derived from large lying-in institutions, in a salient manner, I will group side by side the percentage of mortality reported by those obstetricians who habitually resort to prophylactic vaginal injections after normal labor, and those who abstain from this interference with the natural processes, trusting to scrupulous external cleanliness and antiseptics.

Hospitals in which injections are practiced.	Mortality, per cent.	Hospitals in which injections are not practiced.	Mortality, per cent.

† Remarks by Dr. Lusk, in discussion of Dr. Thomas's paper.

In compiling these statistics, I have exercised the greatest care to exclude all institutions whose methods of antiseptics are not clearly defined in published records. It has been my aim to further the progress of puerperal management by pointing out that, while the improvement in such hospitals as the Charité has been remarkable since the adoption of strict antiseptic cleanliness, there is still a vast difference in favor of such hospitals as those of Prague under Breisky and of Paris under Tarnier, the mortality in the Charité being, say for 1882, 1·8 per cent., and the mortality under Breisky and Tarnier, for the same year, *nil*. Wherein lies the difference in the antiseptic methods of these institutions? *Chiefly, perhaps solely, in the use of prophylactic vaginal injections after normal labor.* It may be said that I am prejudiced in favor of this view. *Let the figures testify!*

In conclusion, I desire to quote some recent utterances on the subject of prophylactic vaginal injections.

Dr. Paul Bar says, in discussing the *puerperal treatment*, after artificial labor even (p. 217):

Voici quelle est, d'après nous la conduite la plus sage. Tant qu'aucun signe fâcheux ne sera apparu, *on devra se borner à faire avec le plus grand soin des lavages vulvaires; si les lochies sont fétides, on aura recours aux injections vaginales.* Dès le premier symptôme d'infection, frisson, fièvre, on aura recours aux injections intra-utérines.

On le voit, pour nous, la méthode antiseptique ne consiste pas à vouloir intervenir quand même. En obstétrique comme en chirurgie on ne doit jamais obéir qu'à des indications précises.

Or, quand pendant les suites de couches, tout est régulier, il est tout indiqué de *s'abstenir de ces injections vaginales répétées.*

Rücksichtlich der Prophylaxis verwirft Breisky sowohl uterine—abgesehen von bereits eingetretener Zersetzung des Uterusgehaltes—wie vaginale Ausspülungen gänzlich. Bei normalem Verlauf hält er mit Spiegelberg, "das in Ruhe lassen" des puerperalen Genitalrohres für das beste Verhalten. Auch Breisky hat sich nicht überzeugen können dass der Weg zur noch grösseren und sicheren Einschränkung der puerperalen Mortalität auf der Seite einer besonderen activen, mit regelmässigen Injektionen in den inneren Genitalien operirenden Prophylaxis zu finden sei.*

Writing of prophylaxis during menstruation, in cases of uterine catarrh, Professor Schultze, of Jena, recommends an external pad of salicylated wadding and carbolized injections into the vagina, etc. "Ein ähnliches Verfahren empfiehlt Verfasser auch den Wöchnerinnen, jedoch mit der Ausnahme der Ausspülungen, weil hierbei durch die selten fehlenden kleinen Wunden, durch das Klaffen des Vulvarandes, durch etwaige Unsauberkeit des Wartepersonals, leicht Gelegenheit zur Infection gegeben werden kann."†

"Are not absolute rest and freedom from disturbance of these tissues (of the lacerated and bruised parturient canal) much more favorable to their restoration than any washes that can be used? Since that time I have considerably surprised my old nurses by directing that *injections should*

never be used unless specially ordered" (Dr. Fordyce Barker* in discussion of Dr. Thomas's paper). "The arguments which have been brought against the practice (vaginal injections every eight hours after labor) since I read my paper have had great weight with me. I confess I feel less firm in my conviction upon this point than I did, and that in future I will examine the question carefully ere I determine to adhere to my plan. You may ask, Why this change of opinion? My answer is that I strive to mend the faults of yesterday with wisdom of to-day" † (Dr. Thomas in his closing remarks).

And, lastly, I would quote Dr. Garrigues himself: "By the effective antiseptic treatment at the entrance, preventive injections become superfluous, and thus *one great source of infection is avoided.*" ‡ His own testimony should convince Dr. Garrigues that he is in error when he asserts that "the hue and cry recently raised against vaginal injections exaggerates very much the dangers of this mode of treatment." It appears to me that the statistics here furnished from the best hospitals and from the most careful followers of obstetric antiseptics, together with the abandonment of prophylactic vaginal injections by Dr. Fordyce Barker, who was the Coryphæus of their employment in this country, and by Dr. Thomas, who not long ago advocated them, should give the *coup de grâce* to this mischievous practice, which I first condemned in the County Medical Society on December 21, 1883. Since that time I have received numerous communications from physicians in various sections of this country, cordially approving my course in opposition to an over-active obstetric prophylaxis. Some of these writers state that they have used vaginal injections after labor "because they are cleansing" and "render the patient comfortable," and they assert that they "have *not yet* discovered harm from them," etc. May their experience not be parallel to mine? I was long loath to admit that these injections, which *seemed* so cleanly and innocuous, could possess an element of danger, until stubborn clinical facts forced the conclusion upon me.

One of my correspondents tells me that he uses the vaginal douche freely, and has "not yet had any reason to think that any septic influences had been occasioned by its use." He states, however, that he had in his private practice one fatal case of puerperal septicaemia last year.

Another gentleman reports to me a case of puerperal infection, also fatal, occurring during the latter part of the second week in a patient whom he had dismissed after a good labor and one week's attendance. He had ordered the vaginal injections to be used during the first and second weeks of the lying-in.

Every physician in large practice may call to mind cases of fever for which he could assign no cause, and in which every precaution (even carbolized vaginal injections) was resorted to.

If the douche was not instrumental in these cases in producing or favoring the development of puerperal infection, it can not be denied that it failed in its mission of prophylaxis.

‡ *Ibid.*

Breisky and Tarnier say: "Everything that is useless is dangerous."

To those physicians who reason upon this subject from their own experience, which must necessarily be small when compared with the experience of such men as Breisky and Tarnier and Stadfeldt, I would commend the careful perusal of these pages. I have offered practical facts, not theoretical arguments, to demonstrate that vaginal injections after normal labor and in the normal puerperal period are not only devoid of value as a prophylactic measure, but that they "may prove a veritable Trojan horse, admitting the enemy whom we are energetically striving to deny entrance into the precincts of the vagina, and thus letting loose the destructive elements among the torn and raw surfaces which expose the lymphatics."*

In conclusion, I offer the following as a comprehensive method of management of labor and puerperal cases, which I have adopted in *private practice*. The general health of the expectant mother should be carefully looked after about one month previous to the expected time of confinement. The urine should be carefully examined, not in the perfunctory way in which this work is usually performed, viz., by heat and nitric acid. The specific gravity, the reaction, and the quantity passed during twenty-four hours should be ascertained. The microscope is the only sure guide to indicate kidney troubles, which may escape the chemical tests. Specimens containing scarcely a trace of albumin, and even specimens presenting no evidence of the presence of albumin to the usual tests, have been examined by myself, with the discovery of tubular epithelium and pus corpuscles, and other specimens have indicated the presence of renal inadequacy, a condition recently described with much ability by Sir Andrew Clark, of London. The latter involves a more serious prognosis in labor cases than a trace of albumin would indicate. A persistent specific gravity below 1.012 should arouse suspicion of its presence. A careful study of the chemical condition of the urine, its exact specific gravity, and its power to eliminate urea and its compounds, and a thorough microscopical investigation of its sediments, will often afford a clew to serious complications in labor which in the past have been mysterious, but which may now be prevented or ameliorated if their origin is discovered in time.

The lying-in chamber should receive special attention; its furniture, carpets, and walls should be cleansed with great care, and kept clean and pure by frequent ventilation and exposure to the sunlight. Modern hygiene teaches the methods by which a correct sanitary condition may be obtained, and every well-informed physician is competent to direct the management of the lying-in chamber with reference to heat, light, and ventilation. Antiseptics, for the purpose of destroying germs on the furniture and bedding, are unnecessary and certainly inefficient, unless each and every portion of bedding, carpet, furniture, and hangings could come into actual contact with a solution sufficiently strong to destroy the disease germs. That is impracticable.

* "Objectional Features of Certain Methods of Prophylaxis against Puerperal Fever," by Simon Baruch, M. D., "Medical Record," February 16, 1884.

In the event of exanthematous disease having prevailed in the house, fumigation with sulphur should be resorted to.

When labor is impending, the woman should take a hot bath, and cleanse herself thoroughly, especially the external genital organs. The bedding may now be managed in the usual manner, viz., by protecting the lower, clean portion with a rubber sheet inserted under the upper sheets upon which the parturient is to lie. If labor be protracted, one or two warm vaginal injections, and an occasional bathing of the external parts with a solution of bichloride of mercury, six or eight grains to the quart, will afford an ample antiseptic purification. Examinations by the touch should be made rarely, and always only after thorough scrubbing of the hands with a nail-brush, soap, and hot water. To prevent contact of the accoucheur's clothing with the genital parts or the thighs of the parturient, a clean towel should be tightly wrapped around the arm of the examining hand, and pinned around the wrist. This may be removed from time to time when it becomes soiled. The use of carbolyzed oil is one of the absurdities of antiseptic practice. It is well known that the regular oleaginous solution of carbolic acid does not possess germicidal properties. Sali-cylated vaseline would be more in accordance with scientific ideas. But strict cleanliness and, if need be, the bathing of the hands in a solution of bichloride of mercury, eight grains to the quart, will afford ample protection against the introduction of disease germs. The napkin which receives the vaginal secretions during labor should be renewed several times, and the bed kept as clean as possible. When the head appears at the perinæum, fecal matter, which often precedes or accompanies its appearance, should be removed at once. This will be accomplished readily if a napkin has been spread under the nates to receive it. Under these circumstances the external genitals should be bathed with a hot solution of corrosive sublimate.

After the birth of the child, the usual attention should be paid to the uterus. Although, according to some recent statistics, Credé's method has not succeeded so well in emptying the uterus completely as the expectant plan, I should be loath to give it up; but I would advise trusting to the natural powers of the post-partum uterus. In fact, Credé directs that the hand resting upon the uterine mass should await a contraction ere the effort be made to aid the expulsion of the placenta by properly applied pressure. It is the officious pressure of the hand upon the uterus which retards expulsion. The careful observance of Credé's direction will always be crowned with success. It is not necessary to mention that all clots should be removed from the utero-vaginal canal.

The patient should now be placed across the bed, opposite a good light, and an examination of the external genitals be made. If a rupture exceeding one quarter of an inch be present, it should at once be united. It is rarely necessary to introduce more than three sutures. I am in the habit of resorting to two or three sutures, as may be indicated by the extent of the rent. It is my practice to enter the suture (silver) about a quarter of an inch from the left edge of the laceration, pass it deep with a long, straight needle, bring it out at the upper portion of the rent, rein-

roduce it at this point into the opposite edge, and again bring it out a quarter of an inch to the right of the rent on the perineal surface. The sutures should be introduced precisely in the same manner as in the secondary operation, deep and thoroughly, and no sign of them should be visible in the vagina. Thus the puckered edge of the mucous lining of the vagina protects the wound against air and against the secretions, especially when, in a day or two, swelling aids this occlusion. The sutures are fastened by twisting them, not too tightly (making allowance for swelling, which in lacerated wounds is necessarily greater than in the incised wound of the secondary operation), and securing them by clamped shot. Although the latter produce small and deep abrasions, these heal in a few days after their removal. It is my practice, in every case of a primipara, to warn the friends of the patient that a ruptured perineum is unavoidable. I assure them that it is a common accident, to meet which I am prepared, and that they need not be alarmed if, after the labor, I proceed to stitch up the wound. I prepare the sutures, needle-holder, etc., in an adjoining room, put them on a tray, and, when the patient is brought forward to the light for examination, have them ready without her notice. She is informed that a thorough examination is necessary, and that it may be a little painful, but will be brief. Thus the suspicions of the attendants and friends are disarmed, their anxiety is allayed, and I am absolved from blame if a rupture occurs.

The introduction of the sutures requires but a few minutes, after a new and thoroughly antiseptic sponge (which is always found in baby's basket) has been introduced within the vagina, to dam up the flow. The passage of the sponge is the most painful part of the procedure. The bowels are kept open with the compound licorice powder, and the stitches are removed from the fifth to the seventh day. I regard this little operation as one of the most successful in surgery, and one which any physician need not hesitate to perform.

A hot vaginal injection should be given after each case of labor, consisting of plain water or, if the labor has been protracted or perineal suture has been performed, of a solution of corrosive sublimate—four to six grains to the quart of water. The woman should now be bandaged, the soiled bed-linen should be removed, after she has been cleansed as usual, and *now a strict abstention from all interference with the genital tract is to be observed.* The vulva must be cleansed as often as necessary, so that nothing shall remain adherent to the hairs; but no sponge should ever approach it. I regard it as important for the thorough drainage of the uterus and vagina to insist upon the patient's using, after the first day, a regular vessel, and not the bed-pan, if her strength permits it. By this means all coagula and retained lochia are removed. If the lochia at any time become offensive, or are too abundant, or if the temperature rises above 102° F., without assignable cause, a vaginal injection of sublimate solution (six grains to the quart) should be carefully administered with a clean fountain-syringe. This is to be repeated as often as may be necessary. If the temperature should rise, a warm uterine irrigation with the same solution is in order. After the irrigation, a pencil of iodoform, ninety to one hun-

dred grains, and fifteen grains each of starch, glycerin, and gum arabic, should be introduced within the uterus. This method renders the utero-vaginal tract completely aseptic for several days, and enables the physician to dispense with frequent intra-uterine injections, which are fraught with danger. Should, however, the temperature not fall, another vaginal injection may be administered and followed by an intra-uterine irrigation with a solution of corrosive sublimate, six grains to the quart of warm water. The phenomenal success of Ehrendorfer's practice, as detailed in the "Archiv für Gynäkologie," Bd. xxii, Heft 1, is an ample guarantee of the safety and reliability of this method of antiseptics in puerperal fevers.

In the event of an artificial labor, or a hæmorrhage, a much more scrupulous antiseptics is called for. Immediately after the termination of such labors, or when placental *débris* are retained, an intra-uterine irrigation (not injection) of the sublimate solution should be resorted to, two quarts being used, and an iodoform suppository must be inserted into the uterus. The same punctilious cleanliness being observed in the management of the bedding, removal of soiled linen, etc., an antiseptic cleansing of the external parts must be executed with a mass of clean lint or absorbent cotton, sponges being avoided. The solution of sublimate used for this purpose should be of the strength of twelve grains to the quart. Now an antiseptic napkin of "lint or Canton flannel (new), eight inches long, and wrung out of this solution, should be placed over the vulva and anus, folded so as to form four layers three inches wide, outside of which is placed a piece of oiled silk an inch longer and broader, and upon this a large pad of carbolized cotton; all are fastened to the binder" (Garrigues). If no fetor or other abnormal condition of the lochia is perceptible, and no fever arises, the genital parts are only to be bathed twice a day with the antiseptic solution, the dressing being renewed each time. No interference with the utero-vaginal tract is permissible unless abnormal symptoms arise. In these cases the first appearance of a chill or fever, which can not be accounted for except as arising from infection, should be the signal for antiseptic irrigations—vaginal at first, intra-uterine if necessary. The plan above briefly delineated should be followed in the event of fever. In placenta prævia, in transverse presentations requiring the introduction of the fingers or hand, vaginal antiseptic injections *during* labor are imperatively demanded. In these and other operative cases the value of strict antiseptics and cleanliness can not be over-estimated, because the reduction of mortality by these measures is one of the greatest triumphs of modern obstetrics. The subsequent management of such cases has been referred to above.

This brief sketch of antiseptic midwifery presents a happy mean between extreme measures, on the one hand, and the purely expectant plan, on the other. It is simple and concise, and has the support of the experience of Breisky and Tarnier, the most successful obstetricians of modern or ancient times. Both of these observers warn against the danger of doing too much, which I have endeavored to emphasize in all my papers and utterances upon the subject.

TONSILLITIS.*

BY T. A. DE BLOIS, M.D.,

LARYNGOLOGIST TO THE BOSTON DISPENSARY; ASSISTANT PHYSICIAN TO THE DEPARTMENT FOR DISEASES OF THE THROAT AND NOSE, BOSTON CITY HOSPITAL.

IN bringing up again this, to say the least, "considerably discussed" subject, it is not with the belief that I have anything original to offer in either pathology, diagnosis, or treatment, but, as I have had the fortune, good or otherwise, to have been thrown almost daily with these cases, it appears to me that, by classing the results of a few years' treatment, an idea of its advisability might be gained.

I might, in order to illustrate the frequency of tonsillitis, in comparison with other affections coming to a special dispensary clinic, state that from the 1st of June, 1880, until the 1st of April, 1883—a space of nearly or during three years of almost daily treatment of diseases of the throat and nose at the Boston Dispensary—I saw 222 cases of tonsillitis in comparison with 2,008 cases, total of all kinds; in other words, eleven per cent. of the whole number of cases. As regards the distribution of these cases throughout the year, taking the year commencing April 1, 1882, to March 31, 1883, as a criterion, there were 819 cases, 110 being of tonsillitis, or 12½ per cent. In April, 77 total, 8 per cent. cases of tonsillitis. May, 63 cases, of which 8 per cent. were tonsillitis. June, 49 total cases, with 2 per cent. of tonsillitis. July, 60, with 20 per cent. of tonsillitis. August, 64, with 12 per cent. of tonsillitis. September, 54, with 9 per cent. of tonsillitis. October, 45, with 9 per cent. of tonsillitis. November, 44, with 20 per cent. December, 24 per cent. January, 26 per cent. February, 18 per cent. March, 7 per cent.

I regret that there has been no means of considering the different states of the weather as being a factor in the causation of tonsillitis; but, from careful observation, it appears to me that a season of damp weather, although warm, is more apt to be the time when we see more of tonsillitis than a season of dryer and colder weather. As regards the causation of this affection, it is extremely difficult, in so many cases that we see once and often not afterward, to say what has led to it.

The theory of a life in a vitiated and effete atmosphere, the presence of decaying animal substances in dissecting-rooms, etc., has been sufficiently written about to be familiar to every one; they may or may not be factors in its production, but certainly the larger part of the tonsillitis patients that we see are not exposed to these conditions, and are so much of their time exposed to the severities of a changeable climate that it would seem as if we ought to look more at the out-door than the in-door surroundings for at least the exciting causes. A low condition of the system, I think, without doubt, shows itself as predisposing the patient to this local glandular affection, just as it might to a series of furuncles, an abscess, or other local lesion of the kind.

We come next to the point of to what class of diseases

tonsillitis belongs. I have always held the opinion, although at variance with that of the majority of authorities, that tonsillitis was not a constitutional disease. I have never seen anything to cause me to change my opinion. I believe the lesion to be entirely a local one, and I think the febrile and other symptoms are as easily accounted for on that ground as those occurring in acute coryza, burns, and other undoubtedly local affections. As to the course of the disease, I can speak with much less self-assertion. I am perfectly honest in my statement that the more I see of it the less I think I know about it. Certainly I never should think of dividing it into classes—as, for instance, a class that "walks" and a class that "stays at home." You may see a patient one day able to walk, and the next day, if you let him alone, he will not be able to walk; and others, if you let them alone, will be better than the day before. So also, as regards the abscess of the tonsil, or around the tonsil, some cases of tonsillitis go on to suppuration in spite of whatever you may do to the contrary; and others, that appear as if they were about to form an abscess, and which will last with great swelling and pain for two weeks and over, will then subside without your being able to find a drop of pus. So, would it not be wiser, or at least more honest, to say that local inflammations of the tonsils differ from each other in degree rather than in kind, and that, when a gland has suppurated, then we know it, and we did not know it before?

Now, I have said that tonsillitis in different cases differs in degree and also in appearances—probably caused by the original size and shape of the tonsil. There are some that appear to be entirely covered in by the reflection of the anterior pillar of the fauces, and then the swelling seems to be rather above and back of them; then, although the pain may be as great, breathing and deglutition will not be so much interfered with. Then there are other cases starting in a tonsil originally large, where the inflammation does not seem to greatly involve the soft palate, but the tumor will be lower; it will be more evident that it is in the gland itself, and there will be more follicular secretion on its surface. But it is the same tonsillitis.

As to diagnosis, it would be better to say differentiation, for, if you can exclude the exanthemata, some of the manifestations of syphilis, and, above all, the local symptoms of diphtheria, you would probably have tonsillitis left. And then there comes the point as to whether tonsillitis ever turns to diphtheria, and the converse. I believe tonsillitis and the local manifestations of diphtheria to be as distinct as I believe the local venereal sore and the primary lesion of syphilis to be, although there are many to whom this simile has no significance, but it is with great difficulty that they are invariably recognized; but when we think we have a case of tonsillitis, and suddenly find a bit of membrane in the larynx or posterior nares, it is much pleasanter to think that one disease runs into the other than to allow that there has been an unfortunate error in diagnosis.

Now, there is, besides these, a pharyngitis or tonsillitis without exudation, only erythema, which we sometimes find in the same house and generally in the same family, and sometimes synchronous with a case of diphtheria. What is

* Read at the Section of Clinical Medicine of the Suffolk District, Mass., Medical Society, March 12, 1884.

this? Is it a lesser form of the same constitutional poisoning, or is it to be classed among the cases of idiopathic tonsillitis? Dr. Mackenzie, from his vast experience, speaks of a form of diphtheria without exudation, and, as the membrane is only a local symptom of diphtheria, why may not some of the symptoms be found wanting in that as in other diseases?

About a year ago I was called to see a woman with throat symptoms. Upon examination, both tonsils and the velum were greatly swollen and of a dark-red color; both tonsils pretty well covered with a white exudation, which I was able to wipe off, leaving white points, through the middle of which the probe passed into the dilated mouths of the follicles; found nothing white in either posterior nares or larynx; the glands of the neck were greatly swollen; temperature 103°. No other symptoms. I believed I had a case of double tonsillitis, and told the friends so; treated with Dover's powder, etc. The next day the tonsils were about the same, but the nostrils contained a whitish matter, watery mucus issuing from them; felt pretty sure then I had a case of diphtheria; and had to hedge a good deal with the inquiring friends. The third day the tonsils were not so bad; the nose was about the same, but externally there was a broad red flush over the bridge of the nose; there was no mistaking it. I couldn't hedge any more; it was one of those rare and severe cases of erysipelas commencing first in the fauces. So I told the family how much I had been mistaken, and the next day another physician was called. I could only console myself by thinking that the treatment had been all right, no matter how it turned out.

Fortunately, there are not many such puzzling cases, and the little point given by Dr. Jacobi—that the small white spots in tonsillitis always cover the orifice of a follicle, whereas in diphtheria they do not necessarily do so—shows us very well in most doubtful cases. The temperature, and the swelling or other condition of the glands of the neck, are of no use whatever; you may or you may not find them in either diphtheria or tonsillitis, and so it is in most of the other points of difference; they answer well enough for one, and they hold good for the other also.

The prognosis, I suppose, is always good, although the duration of the disease is so very uncertain; they certainly almost always get well. The cases where an abscess has formed and bursts during sleep, strangling the patient, are, of course, well known to every one. There are cases where attacks of tonsillitis rapidly succeed each other, and where the tonsils do not go back to their normal state, gradually becoming hypertrophied together with a much congested condition. This state ought to be taken into consideration when speaking of the invariably favorable prognosis in tonsillitis.

The treatment of tonsillitis is, perhaps, the hardest part of the subject to touch upon. Everybody who gets a case of tonsillitis treats it, and there are, generally speaking, as many modes of treatment as there are physicians who treat it. Like oysters, the tonsils are boiled, steamed, or frozen, according as the medical attendant may fancy the hot gargle, hot spray, or ice treatment. Nothing can be said against these; it is all done with the one object in view of

relieving the symptoms, and, of necessity, the treatment employed exemplifies the past experience and best judgment of the practitioner; what right has one to criticise the judgment any more than the taste of another?

The treatment which I have employed from time to time during the past few years in tonsillitis has most certainly been modified by my daily experience, but, although it has not always been what would please the most fastidious taste, still I have never hesitated to employ it in my own case when I thought I required it, and I can not say that I think I suffered greatly from the treatment. My first efforts were with astringents and escharotics. I used a good deal of iodine and nitrate of silver, and I do not believe that I got brilliant results; it would be absurd to say that I should have done better had I employed some other line of treatment, for that would be only conjecture. I combined this with the constitutional exhibition of iron and quinine, which seemed to have some good effect on the general malaise, not to speak of the slight local astringent effect. I never knew of any very protracted cases; I do not believe I shortened the course much—do not think I lengthened it.

Observing the tension of the parts during the first few days of some cases of tonsillitis, and believing, in many of these, the almost tetanic closure of the jaws was due to this tension, above all, remembering the relief afforded by the early incision of a furuncle, I adopted the plan of scarifying the tonsils with many shallow punctures; by this some little local bleeding was produced, and in almost all cases alleviation of pain; the jaws in some cases could be separated half an inch to an inch farther immediately after the operation. As far as I could judge, this treatment, combined with the use of tonics, has shortened the course of the affection a day or so. It seemed satisfactory, and in some cases I have continued the same treatment ever since. Guaiacum, combined with chlorate of potash and currant paste, I have found invaluable in the form of troches, as they do not taste very badly. Within the past year I have adopted the use of the Dover's powder—ten grains the first night, five the second, and five the third night, to be in each case followed by a saline cathartic in the morning; it does not always produce perceptible diaphoresis, it seems to relieve as much when it does not as when it does.

This treatment, followed by tonics, I have found very good; it relieved some of the symptoms; it may have shortened the disease. I used this in ten out of eighty cases. On the whole, believe I have had better results than from scarification, and, of course, it is better where the tension is not very great. Some years ago, having tonsillitis myself, I wanted to try the aconite treatment. I had no aconite at hand, but had some $\frac{1}{10}$ gr. aconitine pills, which it seemed to me ought to do about as well. I used them often enough to produce severe toxic symptoms, but did not get the least relief to the tonsillitis. I have lately seen the aconite treatment in two cases; one was relieved and the other was not.

My principal objection to the use of aconite in dispensary practice is the great stupidity of the patients. It is a frequent occurrence, when prescribing for pharyngitis a gargle and a tonic, to have the patient return and acknowledge that he has swallowed the gargle and gargled with the

tonic; now, under such conditions should we be justified in trusting such people with the use of so dangerous a remedy as aconite, which is generally prescribed by the drop? Hot water I have never used, except in catarrh and coryza, as an injection into the nose. I did not find it of much effect in these instances.

In conclusion, I can make these few deductions from my experience alone, and I only refer to my own experience. For a self-limited disease it is somewhat uncertain as to this limit; its diagnosis is generally very easy, but there are good opportunities for mistakes in some cases.

Different forms of treatment have had such different results in physicians' hands that it is wiser to make no suggestions, but leave each one to follow out his idea, or the result of his own experience.

CASES COMING UNDER THE THROAT DEPARTMENT, BOSTON DISPENSARY,
FROM JUNE 1, 1880, TO APRIL 1, 1883—TOTAL, 2,008 CASES.

Clinical Reports.

CASES IN PRIVATE PRACTICE.

By J. FOSTER BUSH, M. D. (HARV.),
BOSTON.

Pleurisy in an Infant.—Rupture of the Membranes; Prolapse of the Funis; Miscarriage.

CASE I.—E. A., a female baby, aged six weeks, was noticed on May 20th to cry a great deal and refuse its food. The cry was peculiar, having a sharp, short sound, very different from the fretting of babies. The nurse noticed a slight cough, and, upon taking up the child, found that the extremities were cold and livid. Heaters were applied to the feet and the body, and a small quantity of brandy in hot water was administered. Soon reaction set in, and the child became hot and restless. It took milk eagerly, but vomited it directly. There was constipation.

On the 21st the child had been restless all night; the cough was short and hard, which caused pain and produced crying. The pulse was rapid; the respiration was 92, short, quick, and labored. Upon making an examination of the chest, the right side was found full, but it did not expand so much as the left; there was flatness upon percussion, and the respiratory murmur

of that side was heard only over the upper part of the chest in front, and there faintly. The child nursed easily, but not much at a time, jerking the head away and breathing hurriedly.

On the 24th the respiration was easy, the temperature was lower, and the dullness was subsiding. There were several loose dejections. On the 26th the percussion sound was more resonant, and the respiratory murmur was audible.

June 1st it continued to gain, and respiration was distinct. Toward evening, however, the respiration began to quicken, the skin became hot and dry, and on June 3d an effusion was discovered in the opposite side of the chest. This ran about the same course as the other, except that the respiratory sounds were feeble for some time, and a hacking cough lasted for a while.

The treatment consisted in keeping the child warm by heaters applied to the feet and body—bottles filled with hot water being used—whenever coldness was perceived. A jacket poultice of flaxseed meal was employed from the first, and, upon its discontinuance, cotton wadding was used to maintain warmth. Besides the breast-milk, beef-tea was occasionally given. Brandy was given in infinitesimal doses, but was invariably rejected by the stomach.

I was not inclined to believe the evidence, as the disease is seldom seen at this early age without some constitutional taint; therefore I requested Dr. H. H. A. Beach to see the child with me, which he did on more than one occasion, and he fully agreed with me in the diagnosis and treatment. According to the standard authorities, it is exceptional for idiopathic pleurisy to occur in a child under five years of age, and, under such circumstances, the effusion is apt to become purulent.

CASE II.—February 18th I was called to see Mrs. W., aged thirty-three. Her statement to me was that she was six months pregnant; that during this period she had been feeling well till within a week, since which time she had been troubled with "the whites" so badly that she had been obliged to wear a napkin, and that the discharge was thin like water. She had experienced no pain, but had flowed a little during the night previous to my visit, having noticed bloody stains on the bed-clothing. In the morning, upon getting up, she felt something peculiar keep hitting her leg, and did not know what to make of it. She had had one miscarriage, but had never had a child at term.

Upon inspection, I found protruding from the vulva a loop of the umbilical cord about eight inches in length. This was pulsating. Upon making a vaginal exploration, I found that the os uteri grasped the funis firmly, and I could not introduce my finger through the os without using more force than I thought was justifiable. I put the patient to bed, and gave an opium pill, directing a second dose to be given if pain required it.

The next morning Dr. W. L. Richardson saw the patient in consultation. There had been pain during the night. Upon inspection, it was found that sloughing of the cord at the turn of the loop had taken place, and pulsation consequently had ceased. Upon making a vaginal examination, the os was found to be dilating and a foot was presenting.

Later in the day, pains having been moderate, the os was opened by manual dilatation, the other foot seized, and delivery accomplished. After delivery there was free hemorrhage, a portion of the placenta being detached and part adherent. The hand was passed into the uterus and the placenta was forcibly detached and removed. Stimulants and the fluid extract of ergot were administered, and a carbolyzed hot-water intra-uterine injection was given, contraction of the uterus following. Convalescence was slow on account of the quantity of blood lost, but was not retarded by any unusual symptoms.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MARCH 22, 1884.

THE MARINE-HOSPITAL SERVICE AND THE NATIONAL
BOARD OF HEALTH.

WHILE it is to be regretted that any clashing should have arisen between the working of the National Board of Health and that of the Marine-Hospital Service, the enormous interests at stake forbid the medical profession, represented as it is in both bodies, and liable to be judged of by the doings of either, to content itself with deprecating the situation of things; it is incumbent on us to look into the merits of the case. We would therefore commend to our readers two publications recently issued by the Treasury Department: the "Report to the Secretary of the Treasury on the Administration of the National Quarantine Service and the Epidemic Fund" (dated February 23, 1884), and the "Answer to the Supervising Surgeon-General to the National Board of Health" (dated March 12, 1884). These pamphlets contain the proceedings of two meetings of the House Committee on Public Health, and embody Surgeon-General Hamilton's defense of the course pursued by the Marine-Hospital Service in administering the epidemic service, and especially of its attitude toward the National Board of Health, both of which had been called in question before the committee.

The hearings before the committee are but the culmination of a contest that has long smoldered. So far as our observation has enabled us to form a judgment, it has been conducted more creditably by Dr. Hamilton than by his antagonists. The Marine-Hospital Service has undeniably done good work in the field opened to it by the action of Congress in charging it with the management of the epidemic fund, and we are unable to see that it has gone out of its way to try to undermine the efficiency of other branches of the sanitary service, or to detract from any credit that the nation may be disposed to award them. On the other hand, there seem to have been indications that the National Board of Health was endeavoring to bolster up its waning influence by pointing to the laudatory resolutions passed by medical societies on various occasions. When we reflect how easily the passage of such resolutions can be secured as a general thing, and how seldom they represent any firm conviction on the part even of those who vote for them, we can only conclude, without at all adopting the suggestion that their passage was the direct result of improper influences brought to bear by the board, that the board virtually confesses its weak position by parading them as evidence of its standing in the medical profession.

The general showing made by Dr. Hamilton before the committee is so creditable to the efficiency of the service of which he is the head that it seems to us to be regretted that petty matters were allowed to figure in the inquiry, and that personal

allusions are so common in the reports of what was said on either side. Even this aspect of the dispute, however, shows much less to the discredit of the Marine-Hospital Service than to that of the representatives of the National Board of Health.

SKILLED TESTIMONY IN INSANITY CASES.

THERE is room for some speculation as to the probable working of a bill that has been prepared by a committee of the Medico-Legal Society, the professed object of which is to do away with certain of the abuses that take place so often in connection with judicial inquiries turning upon the question of insanity, as well as to develop a little popular respect for "expert testimony." It is provided in the bill that, in each judicial department of the State, a body of medical "experts" in psychiatry shall be appointed, and that any litigant desiring testimony on the subject shall apply to the court, which shall determine the number of such witnesses to be called, their names, and their fees. These witnesses having been selected, it is provided that "no other mental experts [*sic*] shall be examined upon such trial."

It seems to us that this latter clause is likely to work great hardship if it is interpreted as covering the attending physician, who may be called to testify as a skilled witness as well as upon matters of fact. Such a physician would have opportunities, in many cases, for forming an opinion sufficiently trustworthy to outweigh the opinions of any number of men who, whatever their knowledge of the general subject, were restricted to answering hypothetical questions, without ever having seen the person whose mental condition was the subject of inquiry. Unless the attending physician is allowed to testify as to matters of opinion, the law not only seems likely to cause injustice, but will probably fail to work satisfactorily—indeed, it may be questioned whether it would not be unconstitutional.

Another section of the bill requires hypothetical questions to be reduced to writing, and allowed by either the adverse party or the judge, before they can be propounded to the witness. To this provision we see no objection in the interest of justice, and it may work well in preventing waste of time in propounding and answering questions which might at the last be held not to cover the case.

A CRUSADE AGAINST OPIUM.

THE evils of the opium habit, or at least its prevalence, may have been overdrawn of late, but certainly there is ground enough for apprehension that the vice will grow rapidly to such proportions as seriously to threaten the well-being of a considerable section of our people. It seems to us, however, that, if legislation is to be called upon to interfere, some less radical measure might be made to serve than the virtual prohibition contemplated in a bill recently introduced into the Lower House of Congress by a representative from California. According to this bill, the importation of the drug, save in the form of aqueous extracts or tincture, is made an offense punishable by a fine of \$5,000 and imprisonment for a term not

exceeding five years. In the interests of medicine and pharmacy, crude opium must be had, but it might be found practicable to guard by legal enactment against its indiscriminate sale. One argument urged in favor of the bill is the assumption that its enforcement would have the effect of diminishing the Chinese population of the country—whether by discouraging immigration or by leading to that mortality which the bill asserts always takes place among the victims of the opium habit when they can not procure the drug, we are not told. For the sake of our civilization, it is to be hoped that the bill covers no political scheme founded on the latter notion.

MINOR PARAGRAPHS.

PRELIMINARY EDUCATION IN OHIO.

We have received a copy of a set of resolutions lately adopted by the Trumbull County Medical Society, recommending the State society to move in the matter of securing provision for requiring a definite standard of educational attainments on the part of medical students as a preliminary to their entering upon the study of medicine. The resolutions embody a schedule of requirements that is certainly to be commended, embracing a written essay, writing from dictation, and examinations in spelling, reading, geography, political economy, ancient and modern history, geology, botany, chemistry, natural philosophy, arithmetic, algebra, geometry, English grammar, and in a very fair elective list of Latin, Greek, French, and German text-books. It is to be hoped that the State society will sanction the scheme, and that its indorsement will meet with favor in the Legislature.

A CONSPIRACY OF DRUGGISTS IN MASSACHUSETTS.

CERTAIN Massachusetts druggists, whose nefarious trade in drugs not up to the legal standard in strength or purity was lately checked for the time being by the energetic action of the State board of health, are conspiring to get the better of the law, and of the community, by securing such modifications of the present laws relating to the matter as will enable them to ply their fraudulent business without let or hindrance. In support of their scheme they have the assurance to allege the fact that a very large proportion of the stock of drugs now on hand in the State could not stand the legal tests, which is tantamount to saying that, because a great many offenses have been committed against a certain law, therefore the law ought to be abrogated. It is to be hoped that the legislators of Massachusetts will not allow themselves to be deceived by any such specious reasoning as this.

THE HEALTH OF CONNECTICUT.

We learn by the last monthly statement of the secretary of the State Board of Health, Dr. C. W. Chamberlain, covering the month of January, 1884, that, with the exception of Hartford, the State has been more than ordinarily healthy. The "winter cholera" of last year does not seem to have made its appearance again, although it is spoken of as having prevailed early in the season in the neighboring State of Rhode Island. As compared with malarial diseases, typhoid fever was the more prevalent of the two. Scarlet fever was more prevalent than during the preceding month, but only six cases of diphtheria were reported. Diseases of the nervous system and erysipelas are said to have been unusually frequent. Pulmonary affections

also figure largely in the report, and the secretary gives it as his opinion that this will continue to be the case until well into the spring.

NEWS ITEMS, ETC.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 18, 1884:

DISEASES.	Week ending Mar. 11.		Week ending Mar. 18.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	3	0	9	2
Typhoid Fever	11	6	10	4
Scarlet Fever	69	8	112	19
Cerebro-spinal meningitis	5	7	4	4
Measles	44	5	62	9
Diphtheria	44	21	62	15

AN INCREASE OF SCARLET FEVER IN NEW YORK.—It will be noticed from the tabular report of infectious diseases in New York, given in this issue of the journal, that there was an increase in the number of scarlet-fever cases reported for the week ending last Tuesday that is quite striking. The number of cases was one hundred and twelve, against sixty-nine for the preceding week, with almost a proportionate increase in the number of deaths from the disease—nineteen for the week against eight for the week before. In comparison, there was a still greater increase in the prevalence of typhus, although the figures are small.

THE FOOT-AND-MOUTH DISEASE has been reported during the past week to be raging in certain parts of Illinois, Missouri, and Kansas, and destruction of the affected cattle, with quarantine measures, has been resorted to with varying degrees of rigor. Doubt seems to be entertained, however, at the East as to the accuracy of the reports, and it is said that no private advices have been received confirmatory of the statements given in the newspapers. A joint resolution has been introduced into Congress appropriating \$25,000 to be expended, under the direction of the Commissioner of Agriculture, in the suppression of the disease in Kansas.

"PINK-EYE."—This disease is said to be prevailing among the horses of Albany and Rensselaer counties, in this State.

TRICHINIASIS.—The Senate Committee on Foreign Relations, if we may judge from a bill it has reported to the Senate, is content to rely on thorough salting as a safeguard against injury from the use of trichinous pork, sufficient time being allowed to elapse to insure the permeation of the meat by the salt.

THE BOSTON MORTALITY FOR THE MONTH OF FEBRUARY is reported to have been seventy-one in excess of that for the same month last year, the estimated rate being 20.9 per mille. One hundred and thirty-one deaths were attributed to zymotic diseases.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—The twenty-third annual commencement was held on Thursday of last week, in Steinway Hall. The graduating class numbered one hundred and forty-nine. The honor-men were as follows: Reginald H. Sayre, of New York; Nathan S. Jarvis, of New York; Lewis R. Morris, of New York; Alanden C. Bridges, of Indiana; Howard H. Young, of New York; and Sigmar Stark, of Ohio.

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.—Dr. Edward Kershner, of the navy, has been appointed professor of naval, military, and State hygiene, permission having been

granted by the Navy Department; Dr. G. F. Whiting has been elected professor of laryngology; and Dr. W. D. McKim has been made professor of operative surgery.

THE WOMAN'S MEDICAL COLLEGE, OF PHILADELPHIA, held its annual commencement on Thursday of last week, and degrees were conferred on a class of twenty-six, including one lady from Burmah.

THE COLLEGE OF PHARMACY OF THE CITY OF NEW YORK held its fifty-fourth annual commencement on Tuesday, the 18th inst., and the degree of Ph. G. was conferred on seventy-four gentlemen.

THE PARIS FACULTY OF MEDICINE.—We learn from the "Progrès médical" that M. Vulpian, professor of experimental pathology, has been given leave of absence for the second semester of the current year, during which time his place will be taken by M. Hallopeau.

WATER GAS is reported by the State Board of Health not to be more detrimental to health than any other illuminating gas.

OLEOMARGARINE is undergoing an investigation by the Committee on Public Health of the State Senate, with reference to its wholesomeness as an article of food. According to some of the witnesses examined, it is a decided improvement on butter made from cream, but it is a significant fact that, so far as we have noticed, there has been no positive testimony to the effect that it can compete with the latter in the open market.

THE STEAMSHIP MEDICAL SERVICE.—Dr. Irwin having lately renewed his criticisms of the Transatlantic steamship companies in the matter of the medical service on shipboard, the companies reply that they hear no complaints relating to its efficiency, but they are careful not to enter into the matter of the accommodations they give their surgeons, a main feature in Dr. Irwin's criticisms.

HOSPITAL SATURDAY AND SUNDAY IN BROOKLYN.—It is announced that the collections amounted to \$5,649.98, yielding a net of \$3,588.81, which is to be divided so as to give the Woman's Hospital \$83.70, the Long Island College Hospital \$444.00, the Eastern District Hospital \$61.23, the Homeopathic Hospital \$644.64, St. John's Hospital \$527.32, the Brooklyn Maternity \$506.42, the Brooklyn City Hospital \$825.47, and the Home for Consumptives \$496.03.

"TRAUMATIC APOPLEXY" is the euphemism under which a coroner's jury has expressed its opinion as to the death of a student in Yale College who died shortly after having been knocked down in a sparring contest with one of his fellow-students.

"ROUGH ON RATS," an arsenical proprietary preparation concerning the indiscriminate and reckless sale of which we have heretofore spoken in terms of deprecation, is reported to have given rise to the poisoning of a family in New Jersey during the past week. There is a suspicion that the poison was administered maliciously, and it is admitted that the suspected person found no difficulty in buying the preparation.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 9, 1884, to March 15, 1884:*

BILLINGS, JOHN S., Major and Surgeon. Granted leave of absence for one month, with permission to go beyond sea, to take effect April 1, 1884. Par. 6, S. O. 61, A. G. O., March 13, 1884.

HEIZMANN, CHARLES L., Captain and Assistant Surgeon.

Leave of absence extended three months. Par. 9, S. O. 57, A. G. O., March 8, 1884.

KNEEDLER, WILLIAM H., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Fort A. Lincoln, D. T. Par. 3, S. O. 26, Headquarters Department of Dakota, March 8, 1884.

WALES, PHILIP G., appointed to be Assistant Surgeon with the rank of First Lieutenant, to date from February 7, 1884, vice Brewster, resigned. Mem., A. G. O., March 10, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending March 15, 1884:*

TERRILL, F. H., Passed Assistant Surgeon. Ordered to Coast Survey steamer Hassler.

MC CARTHY, R. H., Passed Assistant Surgeon. Relieved from the Coast Survey steamer Hassler, and waiting orders.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, March 24th:* Medical Society of the County of New York.

Tuesday, March 25th: New York Surgical Society (private); New York Dermatological Society (private); Jersey City Pathological Society; Medical Society of the County of Lewis, N. Y.

Wednesday, March 26th: New York Pathological Society; American Microscopical Society of the City of New York; Auburn (N. Y.) City Medical Association.

Thursday, March 27th: New York Academy of Medicine (Section in Obstetrics and Diseases of Women and Children); Harlem Medical Association (private); Brooklyn Pathological Society.

Friday, March 28th: New York Clinical Society (private); New York Society of German Physicians (private); Yorkville Medical Association (private).

OBITUARY NOTES.

DR. LUNSFORD P. YANDELL, OF LOUISVILLE.—Lunsford Pitt Yandell, M. D., the son of a distinguished physician of the same name, died at his home in Louisville, Ky., on Wednesday, March 12th, in the forty-seventh year of his age. The cause of his death was an attack of angina pectoris, from which affection he is said to have suffered frequently. Dr. Yandell was a native of Tennessee, but for the greater part of his life he was a resident of Louisville, where he received both his general and his medical education. At the time of his death he was the professor of the theory and practice of medicine in the University of Louisville and the senior editor of the "Louisville Medical News." He was an eloquent teacher, a forcible writer, and in every way a man of weight in the profession and in the community.

Proceedings of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Meeting of February 27, 1884.

JOHN A. WYETH, M. D., Chairman *pro tem*.

PRIMARY CANCER OF THE HEAD OF THE PANCREAS.—DR. GEORGE A. DIXON presented specimens showing cancer of the head of the pancreas, with secondary deposits in the liver. The patient, a man fifty-four years of age, single, a laborer, entered Charity Hospital November 27, 1883. His family history was good. In September he had strained himself across the abdomen in lifting. Two weeks later he was troubled with pain over the upper part of the abdomen, which was dull and increased by pressure. He vomited blood five weeks after the injury, but the quantity was not known. The pain slowly in-

creased in severity, and he said he had lost thirty pounds since the injury. He had been a moderate drinker, but denied having had syphilis. On admission, his skin and conjunctivæ were of a yellowish tinge, the mucous membranes were pale, and he was much emaciated. Examination revealed emphysema and bronchitis. The heart sounds were weak. There was marked tenderness over the liver, which was of normal size. The gall-bladder could not be felt. He failed rapidly, and the jaundice steadily increased. For two weeks preceding death there was frequent vomiting of a grayish fluid. The patient became delirious two days before death, which occurred January 12, 1884.

At the autopsy the lungs were found emphysematous, and there was cardiac hypertrophy with dilatation. The origin of the common bile-duct was three inches below the pylorus; just below this there was an irregularly shaped ulcerated surface, which involved the mucous membrane of the duodenum. Corresponding thereto there was a tumor, which occupied the position of the head of the pancreas. The latter structure had been invaded by a cancerous mass of the scirrhus variety. It surrounded the intestine, and measured about two inches and a quarter in thickness. The liver was normal in size, and contained a few small nodules, hard to the feel and scirrhus in character. The gall-bladder was enlarged, and the bile-ducts were pervious.

Dr. Dixon related the history of a case which he had seen in Bellevue Hospital while he was an interne there, in 1877—a case of cystic degeneration of the pancreas. The patient had been well up to August of that year, when he was seized with a very severe pain in the epigastric region, radiating toward the back and the right shoulder; there was vomiting, but no jaundice. He was able to resume his work the next day. In September he had a similar attack, but again was able to return to work; a third attack occurred one week later, which disabled him from work, and jaundice set in and increased, and measuring with constant nausea and frequent vomiting. In the epigastric and right hypochondriac regions there was a tumor, attached to and movable with the liver, tender on pressure, and measuring about four inches in its transverse diameter. This was aspirated, and four ounces of reddish-yellow serum were drawn off. The next day the tumor was smaller, but on the second day it was larger than before. There was constant vomiting. On December 17th the patient was suddenly seized with sharp pains, as in previous attacks, became unconscious, and died in the afternoon. The autopsy showed the gall-bladder full of bile, the ducts being pervious. A large cyst occupied the place of the head and part of the body of the pancreas. This cyst pressed upon the ductus choledochus communis, and occluded it.

Dr. Dixon made some remarks upon the literature of these subjects, and called attention to there having been, in the case of cancer, no tumor felt during life, although carefully searched for; and to the vomiting having occurred as a late symptom—whereas, in the case of cystic degeneration, a tumor was found on admission, and vomiting was a very early symptom. In both cases the jaundice was due to pressure on the common duct.

TUBERCLE OF THE TESTICLE.—The CHAIRMAN presented the left testicle removed from a man twenty-seven years of age, who gave a history of inflammation of this organ developing slowly for two years. There was no history of traumatism or of syphilis, but there was a family history of phthisis. There seemed to be a general broken-down condition of the testicle, with two or three points of ulceration; there was pus in the tunica vaginalis testis. The temperature was the varying temperature of phthisis. There was some dullness at the apex of one lung, to which, however, little importance was attached. From the physical signs, from the peculiar temperatures, and

from the family history, Dr. Wyeth made a diagnosis of tuberculosis testis. Knowing that the organ was ruined, and fearing general inoculation, he performed extirpation. It was his rule in performing the operation to transfix the cord well up near the external ring, lay the vas deferens aside, not tying it, and, if necessary, tie the artery of the vas deferens separately, to prevent hæmorrhage, and then tie the vessels and nerves all together with a strong double ligature. The patient made a good recovery.

Dr. F. N. ORRIS thought the case a perfectly clear one of tuberculosis testis, and that there was no doubt as to the propriety of the operation. He had seen a number of cases of tuberculosis of the testis develop apparently in consequence of great irritation to the genito-urinary apparatus. One case which came to mind was presented to the society a number of years ago. The first evidence of trouble was frequent and painless micturition, which continued for a number of months, and finally cystitis developed. There was evidence of calculous material passing, but exploration failed to reveal stone in the bladder. About two years from the occurrence of the original difficulty the testicles began to swell, first one and then the other, and suppuration occurred at several points. It was the opinion of those who saw the patient that there was tuberculosis of the testes. The patient finally died of rupture of a spinal abscess, which had been recognized only a few months before. At the autopsy, tuberculosis of the testes and deposits of tubercular matter in the kidneys were found. There were no tubercular deposits elsewhere in the body. There was no family history of tuberculosis. Dr. ORRIS thought the genito-urinary trouble was due to irritation reflected back from irritation of some of the spinal nerves. There had previously been hip disease, from which the patient had recovered, but with some deformity.

Dr. J. H. RIPLEY thought the previous existence of hip disease showed a predisposition to tuberculosis, for frequently scrofulous manifestations healed in one part of the body and afterward broke out in other parts, while the former seat of trouble remained healthy. He thought the temperature mentioned by Dr. Wyeth as being present in his case, 103° F. in the afternoon, was high for uncomplicated tuberculosis of the testicle.

Dr. A. G. GERSTER had seen a number of cases of tuberculosis testis in which the temperature went even above 103°, as high as 105°. He thought, however, that so high a temperature did not occur unless there were complicating pulmonary trouble, or the deposits in the testicles were in the active breaking-down stage.

The CHAIRMAN thought an early operation was necessary in such cases, and that as much of the serotal tissue should be removed as could be spared, making sure that none of the affected tissue remained.

ANGIOMA OF THE LIP.—Dr. GERSTER presented the lower lip of a man, thirty-one years of age, who, thirteen years ago, was operated upon by Professor Koenig for an angioma of the lip of about the size of a hazel-nut. The cicatrix remained firm for ten years. The patient entered the German Hospital three years later, when a relapse of the old disease was found. Almost the whole of the lower lip was occupied by the growth. The specimen was of interest pathologically, as showing the possibility of a recurrence of this otherwise non-malignant disease after the lapse of ten years. The tumor belonged to the cavernous variety, and consisted of a stroma of connective tissue permeated by a large number of irregularly shaped veins.

The CHAIRMAN said this specimen was one of more than ordinary interest to him from the fact that lately he had done some operations for the removal of these angiomas which did not meet with the approval of surgeons of former years. He

had removed a number from different parts of the face, nose, and forehead, all being of the capillary variety, or a step between cirroid aneurysm and cavernous angioma. He removed the tumor almost entire by one sweep of the knife, cutting down to the bone. The cicatrix which remained after the operation was almost imperceptible.

MYO-FIBROMATA OF THE DUODENUM.—Dr. FRANK FERGUSON presented a tumor which was of interest on account of its situation. It was removed from the body of a middle-aged woman, grew externally from the duodenum, and consisted of a myo-fibroma. From the large number of blood-vessels which supplied it, one would suppose that, had the woman lived longer, it soon would have interfered with the function of the duodenum by pressure. This was the only case of fibroma which he had seen developed in this situation.

UTERINE FIBROMATA.—Dr. FERGUSON presented a second specimen, which was removed from the body of a woman who died at St. Luke's Hospital eight months ago. She had been in the hospital about eight weeks. She was about thirty years of age, and her menstruation was normal, having been interrupted by seven pregnancies, all of which went to natural term. About fifteen months prior to death she first noticed trouble in the pelvic organs. At that time she began to suffer from pain in the pelvic region, from backache, and from gastric disturbance. Afterward she felt a tumor in the right inguinal region, which grew slowly, and at the end of eight or nine months it was apparently as large as a goose's egg. Ascites then developed. After admission to the hospital she had hemorrhage for the first time, and it proved alarming. The operation for which she entered the hospital—removal of the uterus and its appendages—was postponed. Another hemorrhage occurred, and the patient died ten days later of exhaustion. At the autopsy the tumor was found to be subperitoneal and pedunculated, and larger than a goose's egg. The uterus was everywhere thickened, and the cavity had a depth of five inches and a half.

CARCINOMA OF THE STOMACH AND LIVER; HORSESHOE KIDNEY.—Dr. FERGUSON presented a third specimen, removed from the body of a man who was admitted to the hospital on the 4th of February of the present year. He had in former years suffered from two attacks of rheumatism. During two years previous to admission he suffered from "bilious" attacks, lasting from two hours to two days, and occurring at intervals of a month. They were characterized by vomiting, loss of appetite, pain, and diarrhoea. The vomited matter never contained blood. During the last four months the patient suffered from a feeling of distress about the stomach after eating, which was slightly relieved by vomiting. Vomiting, however, rarely took place. Five or six weeks before death he began to suffer from dull, aching pains in the calves of the legs, and three weeks later from slight but constant pain in the stomach, uninfluenced by eating. He lost flesh, and became pale and cachectic. On the 12th of February there was nausea, with vomiting of blood and bloody stools. There was a similar attack on the 17th. During the last hours of life there was severe pain in the epigastrium. He died apparently of heart failure. At the autopsy the cardiac end of the stomach was found nearly surrounded by a cancerous ulcer, and the adjoining mucous membrane was thickened; the liver was studded with numerous white nodules, surrounded by almost normal structure. Microscopical examination showed that in both the stomach and liver the diseased tissue presented large cuboidal epithelial cells arranged in a very fine stroma of fibrous tissue. The kidney was the so-called horseshoe kidney. It was the seat to a slight degree of chronic diffuse nephritis. It also contained cancerous nodules.

Dr. GERSTER said that some years ago Dr. Glück presented at another society a myo-fibroma of the duodenum which pro-

truded inwardly, ulcerated, and gave issue to a fatal hemorrhage through the mucous membrane into the duodenum.

Meeting of March 12, 1884.

GEORGE F. SHRADY, M. D., President, in the chair.

Dr. T. MITCHELL PRUDDEN presented a specimen of *HYDATIDS OF THE LIVER*, and Dr. R. W. AMIDON several of *NASAL POLYPI*, for candidates for membership.

Malformation of the Heart; Open Foramen Ovale and Ductus Arteriosus; Stenosis of the Aorta; Hypertrophy of both Ventricles.—Dr. L. EMMETT HOLT presented a specimen illustrating these conditions, taken from a child which died, at the age of four months, from capillary bronchitis of four days' duration. The heart weighed two ounces and a half, which was about three times the usual weight at that age. The walls of the right ventricle were about as thick as those of the left, and the latter were hypertrophied. The ductus arteriosus was pervious, its caliber being equal to that of the subclavian artery. On the cardiac side of this opening, and beyond the origin of the great vessels, the aorta showed a well-marked constriction, which must have diminished its lumen at least one third. The valves were all normal. There was no marked hypertrophy of the auricles, and no history of cyanosis. The opening of the foramen ovale admitted an ordinary lead-pencil easily, but was valvular in character, and probably did not allow any considerable commingling of the blood of the auricles. The hypertrophy of the left ventricle seemed plainly due to the contraction of the aorta. The cause of the hypertrophy of the right ventricle was not quite so clear, but it seemed to depend upon the same lesion. This obstruction existing at the time of birth, the right ventricle had continued to do after birth part of the work of the systemic circulation, supplementing the left ventricle. These results—open foramen ovale and ductus arteriosus, and hypertrophy of the right ventricle—were very common, depending upon pulmonary stenosis, and compensating for it. Dr. Holt had never met with the same condition as compensatory to aortic stenosis. A second point of interest was the absence of cyanosis. So far as it bore upon this subject at all, the case went to confirm the view that this symptom did not depend upon admixture of the arterial and venous blood. Considerable admixture certainly took place through the ductus arteriosus, possibly some through the foramen ovale. Dr. Holt thought it pretty well established that we were not to look for cyanosis in malformations of the heart unless marked pulmonary obstruction existed. Even this was sometimes compensated for, as above indicated, so that the symptom was wanting.

Dr. J. A. WYETH thought that, inasmuch as Dr. Holt had said the foramen ovale remained open, it was not perfectly clear that the hypertrophy of the right ventricle was altogether due to permanency of the ductus arteriosus and constriction of the aorta. Dr. Wyeth thought also that the condition must be a very rare one. With regard to the last remark made by Dr. Holt, he once presented a specimen, from a woman about forty years of age, in which the foramen ovale presented an opening that would admit his little finger, and yet there was a valve-like arrangement through which he thought blood could not have passed in any considerable amount.

TUMOR OF THE DURA MATER; BEING A CONTRIBUTION TO THE THEORY OF CEREBRAL LOCALIZATION.—Dr. G. L. PEABODY said he would present a brain with a tumor of the dura mater which was an interesting contribution of a negative kind to the doctrine of localization. The patient was seventy years of age, a native of the United States, a druggist, who was admitted to the New York Hospital, January 8th, at 7 p. m., in a comatose state, and the history had to be obtained from his friends. He

had always been a good liver, but was not a drunkard. There had been no seizures suggestive of epileptic or apoplectic attacks. The patient had been in good health, but of late had had trouble in business matters. Half an hour before admission he was seen to slip and fall when walking on the street. He got up almost immediately and walked into a bar-room, complaining of headache and vertigo. After fifteen minutes he became unconscious and passed into a comatose state. The reflexes were found almost completely abolished; there was no facial paralysis; the pupils were moderately dilated and irresponsive to light. A hæmatoma of the scalp existed over the left parietal region, but there was no apparent fracture. The respiration was stertorous; the pulse rapid and shallow; the temperature gradually rose, and before death went above 104° F. The patient died twelve hours after admission. At the autopsy there was marked œdema of the lower extremities. There was a hæmatoma in the left parietal region under the scalp, and one between the pia and dura beneath, causing flattening of the convolutions on the opposite side. In the superior parietal region, just posterior to the ascending parietal convolution, and a centimetre distant from the median fissure, on the left side, was a tumor, hemispherical in shape, 4.3 cm. in diameter, lying beneath the dura and over the pia, and causing cerebral depression. Microscopically, it was a spindle-celled sarcoma. There was also hypertrophy of the left ventricle of the heart, with chronic diffuse nephritis, and œdema and congestion of the lungs, and the liver was fatty and cirrhotic.

The PRESIDENT said it was to be presumed that the sarcomatous tumor had been of slow development, and perhaps the absence of symptoms might be accounted for by the fact that the brain had thus accommodated itself to pressure.

Dr. AMIDON remarked that it was extraordinary to what an extent the brain substance could be compressed by a growth or a foreign body coming from the periphery, without producing special symptoms, provided the pia mater and the cortex were not invaded or subjected to inflammatory action. He had once seen a case of pachymeningitis in which the motor area was compressed to the extent in the thickest portion of the exudation, of about 3 cm. The diameter of the area was from 12 to 15 cm. The patient presented no symptoms until just before death. He died in coma. There were no decided motor symptoms. He presumed that, if, in Dr. Peabody's case, an examination could have been made, no motor symptoms would have been found, but there would very likely have been a choked disc, probably on the same side with the lesion.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of February 6, 1884.

(Concluded from page 287.)

THE CLINICAL ASPECTS OF CEREBRAL SYPHILIS.—Dr. HORATIO C. WOOD concluded his paper as follows:

Epilepsy.—Epileptic attacks are a very common symptom of meningeal syphilis, and are of great diagnostic value. The occurrence in an adult of an epileptic attack, or of an apoplectic fit, or of a hemiplegia after a history of intense and protracted headache, should always excite grave suspicion.

Before I read Professor Fournier's work on "Nervous Syphilis," I taught that an epilepsy appearing after thirty years of age was very rarely, if ever, essential epilepsy, and, unless alcoholism, uræmic poison, or other adequate cause could be found, was, in nine cases out of ten, specific; and I therefore quote with satisfaction Professor Fournier's words: *L'épilepsie vraie ne fait jamais son premier début à l'âge adulte, à l'âge mûr. Si un homme adulte, au-dessus de 30, 35 à 40 ans, vient à être pris pour la première fois d'une crise épileptique, et cela dans la*

cours d'une bonne santé apparente, il y a, je vous le répète, huit ou neuf chances sur dix pour que cette épilepsie soit d'origine syphilitique.

Syphilitic epilepsy may occur either in the form of petit mal or of the haut mal, and in either case may take on the exact characters and sequence of phenomena which belong to the so-called idiopathic or essential epilepsy. The momentary loss of consciousness of petit mal will usually, however, be found to be associated with attacks in which, although voluntary power is suspended, memory recalls what has happened during the paroxysm—attacks, therefore, which simulate those of hysteria, and may lead to an error of diagnosis.

Even in the fully developed type of the convulsions the aura is only rarely present. Its absence is not, however, of diagnostic value, because it is frequently not present in true essential epilepsy, and it may be pronounced in specific disease. It is said that, when in an individual case the aura has once appeared, the same type or form of approach of the convulsion is thereafter rigidly adhered to. The aura is sometimes bizarre; a severe pain in the foot, a localized cramp, a peculiar sensation, indescribable and unreal in its feeling, may be the first warning of the attack.

In many, perhaps most cases of specific convulsions, instead of a paroxysm of essential epilepsy being closely simulated, the movements are in the onset, or, more rarely, throughout the paroxysm, unilateral; indeed, they may be confined to one extremity. This restriction of movement has been held to be almost characteristic of syphilitic epilepsy, but it is not so. Whatever diagnostic significance such restriction of the convulsion has is simply to indicate that the fit is due to a cortical organic lesion of some kind. Tumors, scleroses, and other organic lesions of the brain cortex are as prone to cause unilateral or monoplegic epilepsy when they are not specific as when they are due to syphilis.

Sometimes an epilepsy, dependent upon a specific lesion implicating the brain cortex, may be replaced by a spasm which is more or less local and is not attended with any loss of consciousness. Thus, a man, aged about thirty-five, now convalescent in the University Hospital, offered a history of repeated epileptic convulsions, but, at the time of his entrance into the hospital, instead of epileptic attacks, there was a painless tic. The spasms, which were clonic, and occurred very many times a day—sometimes every five minutes—were very violent, and mostly confined to the left facial nerve distribution. The trigeminal was never affected, but in the severer paroxysms the left hypoglossal and spinal accessory nerves were profoundly implicated in all of their branches. Once fatal asphyxia from recurrent laryngeal spasm of the glottis was apparently averted only by the free inhalation of the nitrite of amyl. The sole other symptom was headache, but the specific history was clear, and the effect of anti-syphilitic remedies rapid and pronounced.

Psychical Symptoms.—As already stated, apathy, somnolence, loss of memory, and general mental failure are the most frequent and characteristic mental symptoms of meningeal syphilis, but syphilis is able to produce almost any form of insanity, and therefore mania, melancholia, erotic mania, delirium of grandeur, etc., etc., may develop along with the ordinary manifestation of cerebral syphilis, or may come on during an attack which has hitherto produced only the usual symptoms. Without attempting any exhaustive citation of cases, the following may be added to:

Dr. A. Erlenmeyer reports ("Die Inetischen Psychosen") a case in which an attack of violent headache and vomiting was followed by paralysis of the right arm and paresis of the left leg with some mental depression; a little later the patient suddenly became very cheerful, and shortly afterward manifested

very distinctly delirium of grandeur with failure of memory. Dr. Batty Tuke reports ("Jour. of Ment. Sci.," January, 1874, p. 560) a case in which, with aphasia, muscular wasting, strabismus, and various palsies, there were delusions and hallucinations.

In the same journal, April, 1869, Dr. S. D. Williams reports a case in which there were paroxysmal violent attacks of frontal headache. The woman was very dirty in her habits, only ate when fed, and existed in a state of hypochondriacal melancholy.

M. Leiderdorf details a case with headache, partial hemiplegia, great psychical disturbance, irritability, change of character, marked delirium of grandeur, epileptic attacks, and finally dementia, eventually cured with iodide of potassium ("Medizin. Jahrbücher," xx, 1864, p. 114). Several cases illustrating different forms of insanity are reported by Dr. N. Manssurow ("Die tertiäre Syphilis," Wien, 1877).

That the attacks of syphilitic insanity, like the palsies of syphilis, may at times be temporary and fugitive, is shown by a curious case reported by Dr. H. Hayes Newington ("Jour. of Ment. Sci.," London, xix, 555), in which, along with headache, failure of memory, and ptosis in a syphilitic person, there was a brief paroxysm of noisy insanity.

Diseases of the Brain Substance.—The psychical symptoms which are produced by syphilis are often very pronounced in cases in which the paralysis, headache, epilepsy, and other palpable manifestations show the presence of gross brain lesions. In the study of syphilitic disease of the brain membranes, sufficient has been said in regard to these psychical disturbances; but the problem which now offers itself for solution is as to the existence or non-existence of syphilitic insanity—i. e., of an insanity produced by specific contagion without the obvious presence of gummatous disease of the brain membranes. Very few alienists recognize the existence of a distinct affection entitled to be called syphilitic insanity, and there are some who deny that insanity is ever directly caused by syphilis. It is certain that insanity often occurs in the syphilitic, but syphilis is abundantly joined with alcoholism, poverty, mental distress, physical ruin, and various depressing emotions and conditions which are well known to be active exciting causes of mental disorder. It may well be that syphilis is in such way an indirect cause of an insanity which, under the circumstances, could not be properly styled syphilitic.

If there be disease of the brain cortex, produced directly by syphilis, of course such disease must give rise to mental disorders, and, if the lesion be situated in such a way as to affect the psychic and avoid the motor regions of the brain, it will produce mental disorder without paralysis, i. e., a true insanity; again, if such brain disease be wide-spread, involving the whole cortex, it will cause a progressive mental disorder, accompanied by gradual loss of power in all parts of the body, and ending in dementia with general paralysis; or, in other words, it will produce an affection more or less closely resembling the so-called general paralysis of the insane, or dementia paralytica.

As a man having syphilis may have a disease which is not directly due to the syphilis, when a syphilitic person has any disorder there is only one positive way of determining how far said disorder is specific—namely, by studying its amenability to anti-syphilitic treatment. In approaching the question whether a lesion found after death is specific or not, of course such a therapeutic test as that just given is inapplicable. We can only study as to the co-existence of the lesion in connection with other lesions known to be specific. Such co-existence, of course, does not absolutely prove the specific nature of a nutritive change, but renders such nature exceedingly probable.

What has just been said foreshadows the method in which the subject in hand is to be here examined, and the present

section naturally divides itself into two: the first considering the co-existence of anatomical alterations occurring in the cerebral substance with syphilitic affections of the brain membranes or blood-vessels, the second being a clinical study of syphilitic insanity.

In looking over literature, I have found the following cases in which a cerebral sclerotic affection coincided with a gummatous disease of the membrane. Gross and Lancereaux ("Affect. nerv. syphilit.," 1861, p. 245) report a case, having a clear syphilitic history, in which the dura mater was adherent to the skull. The pia mater was not adherent. Beneath, upon the vault of the brain, was a gelatinous exudation. The upper cerebral substance was indurated, and pronounced by M. Robin, after microscopic examination, to be sclerosed. At the base of the brain were very atheromatous arteries and spots of marked softening.

Dr. Jos. J. Brown ("Jour. of Ment. Sci.," July, 1875, p. 271) reports a case in which the symptoms were melancholia, excessive irritability, violent outbursts of temper, very positive delusions, disordered gait, ending in dementia. At the autopsy, which was very exhaustive, extensive syphilitic disease of the vessels of the brain and spinal cord was found. The pia mater was not adherent to the brain. The convolutions, particularly of the frontal and parietal lobes, were atrophied with very wide sulci, filled with bloody serum. The neuroglia of these convolutions was much increased, and "appeared to be more molecular than normal; the cells were degenerated and in many places had disappeared, their places being only occupied by some granules." These changes were most marked in the frontal convolutions.

H. Schüle reports ("Allgem. Zeitschrift f. Psychiatrie," xxviii, 1871-'72) a very carefully and meritoriously studied case. The symptoms during life exactly simulated those of dementia paralytica. The affection commenced with an entire change in the disposition of the patient; from being taciturn, quiet, and very parsimonious, he became very excited, restless, and desiring continuously to buy in the shops. Then failure of memory, marked sense of well-being, carelessness, and indifference for the future developed consentaneously with failure of the power of walking, trembling of the hands, inequality of the pupils, and hesitating speech. There was next a period of melancholy, which was in time followed by continuous failure of mental and motor powers, and very pronounced delirium of grandeur, ending in complete dementia. Death finally occurred from universal palsy, with progressive increase of the motor symptoms. At the autopsy, characteristic syphilitic lesions were found in the skull, dura mater, larynx, liver, intestines, and testicles. The brain presented the macroscopic and microscopic characters of sclerosis and atrophy; the neuroglia was much increased, full of numerous nuclei, the ganglion cells destroyed. The vessels were very much diseased, some reduced to cords; their walls were greatly thickened, and full of long, spindle-shaped cells, sometimes also containing fatty granules.

Dr. C. E. Stedman and Dr. Robert T. Edes report ("Am. Jour. of the Med. Sci.," lxi, 433) a case in which the symptoms were failure of health, ptosis, trigeminal palsy with pain (anæsthesia dolorosa), finally mental failure with gradual loss of power of motion and sensation. At the autopsy the following conditions were noted: apex of the temporal lobe adherent to dura mater and softened; exuded lymph in neighborhood of optic chiasm; sclerosis of right Gasserian ganglion, as shown in a marked increase of the neuroglia; degeneration of the basal arteries of the brain.

These cases are sufficient to demonstrate that sclerosis of the brain substance not only may coexist with a brain lesion, which is certainly specific in its character, but may also present the

appearance of having developed *pari passu* with that lesion, and from the same cause.

It has already been stated in this memoir that cerebral meningal syphilis may coexist with various forms of insanity, and cases have been cited in proof thereof. It is, of course, very probable that in some of such cases there has been that double lesion of membrane and gray brain matter which has just been demonstrated by report of autopsies; further, if we find that there is a syphilitic insanity, which exists without evidences of meningal syphilis, and is capable of being cured by anti-specific treatment, such insanity must be considered as representing the disease of the gray matter of the brain. Medical literature is so gigantic that it is impossible to exhaust it, but the following list of cases is amply sufficient to prove the point at issue—namely, that there is a syphilitic insanity which exists without obvious meningal disease and is capable of being cured by anti-syphilitic treatment.

No.	Reporter and Journal.	Symptoms.	Results. Remarks.
1	Louis Streisand . . . "Die Lues als Ursache der Dementia," Inaug. Diss., Berlin, 1878.	Epilepsy, delirium of exaltation, alteration of speech, headache, failure of memory.	Rapid cure with mercury.
2	<i>Ibid.</i>	Delusions, delirium, general mania, great muscular weakness.	Cure with mercurial cury.
3	Dr. Müller, of Leutkirch. "Journ. of Mental Dis.," 1873-'4, 561.	Symptoms resembling general paralysis, and diagnosis of such made until a sternal node was discovered.	Cure by iodide of potassium.
4	Fr. Esmarch and W. Jersen. "Allgem. Zeitschrift f. Psychiatrie."	Sleeplessness, great excitement, restlessness, great activity, incoherence, and violence.	Cure by mercury.
5	M. Leidesdorf . . . "Medizin. Jahrbücher," xx, 1864, 1.	Complete mania, played with his excrement, and entirely irrational.	Complete cure by iodide of potassium.
6	Dr. Beauregard . . . "Gaz. hebdom. de sci. méd. de Bordeaux," 1880, p. 64.	Symptoms resembling those of general paralysis.	Cure by iodide of potassium.
7	M. Rendu <i>Ibid.</i>	Loss of memory, headache, irregularity of pupils, ambitious delirium, periods of excitement, others of depression, embarrassment of speech, access of furious delirium, ending in stupor.	Mercurial treatment, cure.
8	<i>Ibid.</i>	Hypochondria, irregularity of pupils, headache, failure of memory, melancholia, stupor.	Mercurial treatment, cure.
9	Dr. Albrecht Erlenneyer. "Die luetischen Psychosen," Neuwied, 1877.	Melancholia with hypochondria, sleeplessness, fear of men, and belief that they were all leagued against him.	Iodide of potassium, cure.
10	<i>Ibid.</i>	Religious melancholia, with two attempts at suicide, ending in mania.	Iodide of potassium, cure.
11	<i>Ibid.</i>	At times very violent, yelling, shrieking, destroying everything she could get hands on, at times erotomania; no distinct history of infection, but her habits known to be bad, and had bone oozena and other physical syphilitic signs.	Iodide of potassium, cure.
12	<i>Ibid.</i>	Epileptic attack followed by a long soporose condition, ending in mental confusion, he not knowing his nearest friends, etc.; almost dementia.	Cured by mercurial inunction.

No.	Reporter and Journal.	Symptoms.	Results. Remarks.
13	<i>Ibid.</i>	Great fear of <i>gens d'armes</i> , etc., mania, with hallucinations, loud crying, yelling, etc., then convulsion, followed by great difficulty of speech.	Cured by mercurial inunctions with iodide internally; subsequently return of convulsions, followed by hemiplegia and death.
14	<i>Ibid.</i>	Great unnatural vivacity and loquacity, wanted to buy everything, bragged of enormous gains at play, etc.; some trouble of speech.	Iodide of potassium, cure. Attended to business and seems as well as before. Relapsed. (See Symptoms.)
	<i>Ibid.</i> Relapse of case 14.	Fifteen months after discharge from asylum, relapse; symptoms developing very rapidly, delirium of grandeur of the most aggravated type with marked progressive dementia, failure of power of speech, and finally of locomotion.	Failure of various antisyphilitic treatment.
15	Dr. A. Erlenneyer. "Die luetischen," etc.	Failure of mental powers, inequality of pupils, trembling of lip when speaking, uncertainty of gait, almost entire loss of memory, once temporary ptosis and strabismus.	Iodide of potassium in ascending doses failed. Recovery under mercurial inunctions.
16	<i>Ibid.</i>	Failure of mental powers, pronounced delirium of grandeur, hallucinations of hearing, failure of memory, strabismus and ptosis coming on late.	Iodide of potassium, corrosive sublimate injections. Cure.
17	<i>Ibid.</i>	Failure of memory and mental powers, slight ideas of grandeur, disturbance of sensibility and motility, aphasia coming on late.	Cure with use of iodide and mercurial inunctions.
18	<i>Ibid.</i>	Melancholia, great excitability, ideas of grandeur, after a long time sudden ptosis and strabismus.	Iodide of potassium failed; mercurial course improved; their joint use cured.
19	<i>Ibid.</i>	Various cerebral nerve palsies, great relief by use of mercurial inunctions, then development of great excitement, delirium of grandeur, failure of memory and mental powers, and finally death from apoplexy; no autopsy.	
20	Dr. J. B. Chapin . . . "Am. Journ. of Insanity," vol. xv, p. 249.	Melancholia with attempted suicide, epilepsy, headache, somnolent spells.	Iodide of potassium, cure.
21	<i>Ibid.</i>	Acute mania, noisy, very destructive; syphilitic disease of tibia.	Iodide of potassium, cure.
22	Dr. Snell	Maniacal excitement.	Cured by specific treatment.
23	Wm. Smith. "Brit. Med. Journ.," July, 1868, p. 30.	Apathetic melancholy, indelicate, speaking only in monosyllables, and much of the time not at all, sullen and menacing.	Rapidly cured by conjoint use of iodide and mercurial. The symptoms first developed three months after chance.

A study of the brief analyses of symptoms just given shows that syphilitic disease of the brain may cause any form of mania, but that the symptoms, however various they may be at first, end almost always in dementia, unless relieved.

Of all the forms of insanity, general paralysis is most closely

and frequently simulated by specific brain disease. The exact relation of the diathesis to true, incurable, general paralysis it is very difficult to determine. It seems well established that among persons suffering from this disorder the proportion of syphilitics is not only much larger than normal, but also much larger than in other forms of insanity. Thus, Dr. E. Mendel ("Progres. Paral. der Irren," Berlin, 1880) found that, in one hundred and forty-six cases of general paralysis, one hundred and nine, or seventy-five per cent., had a distinct history of syphilis, while in one hundred and one cases of various other forms of primary insanity only eighteen per cent. had specific antecedents.

Various opinions might be cited as to the nature of this relation between the two disorders, but for want of space the curious reader is referred to the work just quoted and to the thesis of C. Chauvet ("Influence de la syph. sur les malad. du syst. nerveux," Paris, 1880) for an epitome of the most important recorded opinions.

Those who suffer from syphilis are exposed in much greater proportion than are other persons to the ill effects of intemperance, sexual excesses, poverty, mental agony, and other well-established causes of general paralysis. It may be that in this is sufficient explanation of the frequency of general paralysis in syphilitics, but I incline to the belief that syphilis has some direct effect in producing the disease. However this may be, I think we must recognize as established the opinion of Voisin ("Paralyse générale des aliénés," 1879), that there is a syphilitic peri-encephalitis which presents symptoms closely resembling those of general paralysis. Such cases are examples of the pseudo-paralyse générale of Fournier ("La syphilis du cerveau," Paris, 1879).

The question as to the diagnosis of these cases from the true incurable paresis is, of course, very important, and has been considered at great length by Voisin (*loc. cit.*), Fournier (*loc. cit.*), and Mickle ("Brit. and For. Medico-Chirurg. Review," 1877).

The points which have been relied upon as diagnostic of syphilitic pseudo-general paralysis are:

The occurrence of headache, worse at night and present among the prodromes.

An early persistent insomnia, or somnolence; early epileptiform attacks.

The exaltation being less marked, less persistent, and perhaps less associated with general maniacal restlessness and excitement.

The articulation being paralytic rather than paretic.

The absence of tremulousness, especially of the upper lip (Fournier).

The failure of antispecific remedies.

When the conditions in any case correspond with the characters just paraphrased, or when any of the distinguishing characteristics of brain syphilis, as previously given in this memoir, are present, the probability is that the disorder is specific and remediable. But the absence of these marks of specific disease is not proof that the patient is not suffering from syphilis. Headache may be absent in cerebral syphilis, as also may insomnia and somnolence. Epileptiform attacks are not always present in the pseudo-paralysis, and may be present in the genuine affection; a review of the cases previously tabulated shows that in several of them the megalomania was most pronounced; and a case with very pronounced delirium of grandeur, in which the autopsy revealed unquestionably specific brain lesions, may be found in Chauvet's thesis, p. 31.

I have myself seen symptoms of general paralysis occurring in persons with a specific history, in which, of these so-called diagnostic differences, the therapeutic test was the only one that

revealed the true nature of the disorder. In these persons a primary, immediate diagnosis was simply impossible.

Case fourteen of our table is exceedingly interesting, because it seems to represent as successively occurring in one individual both pseudo and true general paralysis. The symptoms of general paralysis in a syphilitic subject disappeared under the use of mercury, to return some months afterward with increased violence, and with a new obstinacy that resisted with complete success antisypilitic treatment. Such a case is some evidence that syphilis has the power to produce true general paralysis.

In conclusion, I may state that it must be considered as at present proved that syphilis may produce a disorder whose symptoms and lesions do not differ from those of general paralysis; that true general paralysis is very frequent in the syphilitic; that the only perceptible difference is one of curability; that the curable sclerosis may change into or be followed by the incurable form of the disease. Whether under these circumstances it is philosophic to consider the so-called pseudo-general paralysis and general paralysis as essentially distinct affections, each physician can well judge for himself.

OPHTHALMOLOGY.

By CHARLES STEEDMAN BULL, M.D.,

LECTURER ON OPHTHALMOLOGY AND OTOLGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY; OPHTHALMIC SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN AND TO THE NURSERY AND CHILD'S HOSPITAL.

(Concluded from page 230.)

EXTENSIVE APOPLEXY OF THE CORNEA.—Mayerhausen ("Centralblatt für praktische Augenheilkunde," September, 1883) reports a very interesting case of this nature, occurring in a man who was burned in both eyes by a lime explosion on July 10, 1880. He saw the patient about two hours after the accident, after most of the particles of lime had been removed. The patient was unable to open either eye, and, when Mayerhausen separated the lids, the palpebral conjunctiva was found greatly reddened and swollen, and the ocular conjunctiva very chemotic. In the left eye the cornea was intact, but in the right eye the entire cornea was milky white and the vision reduced to quantitative perception of light. The necrotic corneal epithelium was removed in fragments, and by July 17th the cornea began to clear up, and the patient went home with directions to continue the iced applications. Twelve days later the patient came again, with marked increase of the ocular injection, the corneal parenchyma again very cloudy and the pupil very narrow. In a few days the injection began to disappear, and on August 7th the poultices were discontinued and a simple lotion of lead-water was employed. On the following day the injection had again returned, the eye was painful, and the cornea showed a peculiar change. The upper half was deeply clouded as before, but the lower half was blood-red, simulating an extensive hyphema. Oblique illumination, however, showed that the blood was in the cornea. When the patient sat up, the level of the blood sank somewhat, and it was seen that the lower third of the cornea was filled with blood which lay beneath the epithelium. Pressure with the probe upon the wall of this blood-cyst showed that there was a detachment of Bowman's membrane from the underlying corneal parenchyma. By means of a pressure bandage and keeping the patient quiet in bed the blood was absorbed quite rapidly, and in two days not a trace of it was to be seen. The case subsequently did well.

THE FILING-OUT OF STRICTURES OF THE NASAL DUCT FOR THE CURE OF CHRONIC DACRYOCYSTITIS.—Tartuferi (*Ibid.*) recommends, as a more rational procedure, the filing or scraping away of the hypertrophic neoplastic tissue which causes stricture of the nasal duct. He makes use of an instrument which consists of a cylindrical steel rod or staff, about one millimetre thick, which ends in a small olive-shaped protuberance about three quarters of a millimetre in diameter and $1\frac{1}{4}$ mm. long. Immediately following this olive-shaped protuberance comes a second, about 1 cm. long and 2 to 3 mm. in diameter. The surface of this second olive is provided with spiral furrows, the divisions between which are sharp cutting edges. When this instrument is passed into the duct with a rotary motion, these cutting edges file or scrape off the tissue which narrows or obliterates the canal. The handle of the instrument has a diameter of 4 mm., and is rough, so that it can be readily revolved between the thumb, index, and middle fingers. Tartuferi first opens into the upper portion of the canal, and divides subcutaneously the internal palpebral ligament. He then introduces a Bowman probe No. 1 into the canal through the stricture, so as to open the way for the file. The latter is then introduced into the lachrymal sac in the direction of the duct, so that the olive-shaped end enters the stricture. As soon as the point is engaged the instrument is pushed slowly downward, and is at the same time rotated on its axis. After it has passed the stricture it should be withdrawn and then passed through again and again in the same manner. The operation may be begun with files of a diameter of 2 mm., and continued with those of $2\frac{1}{2}$ and 3 mm. in diameter. The after-treatment consists in the introduction of cylindrical fish-bone probes, of the same diameter as the file employed, and in injections of astringent or alterative fluids to act upon the mucous membrane of the lachrymal sac.

THE ESTIMATION OF REFRACTION BY RETINOSCOPY BEFORE AND AFTER ATROPINIZATION.—Story ("Ophthalmic Review," October, 1883) has been making some investigations into the value of retinoscopy as a means of estimating refraction, and here gives the results of his observations, before putting the patient under the influence of atropia. There were in all nineteen eyes examined, belonging to ten individuals. Of these eyes, eleven were non-astigmatic, and all these were myopic; four showed compound hypermetropic astigmatism; two simple hypermetropic astigmatism; and two mixed astigmatism. In the eleven myopic eyes, atropia left the refraction in four of them unaltered, in four it reduced the myopia by 0.5 D, and in three it produced an apparent increase of myopia, varying from D 1 to D 1.75. Two of these last three cases are accounted for by imperfect atropinization. In the six eyes examined with hypermetropic astigmatism, the refraction in a meridian remained only twice unaltered; it diminished twice by D 0.5, three times by D 1, four times by D 1.50, and once by D 2. In the two eyes with mixed astigmatism the refraction in the principal meridians diminished three times, and apparently increased once, the hypermetropia in one meridian being found lessened by D 0.25. This increase in the refraction is so small that it must be attributed to an error of observation. In the fifteen cases left, suitable for the purposes of the present inquiry, it is found that: The refraction of a meridian remained unaltered ten times; it diminished by D 0.50 eleven times, by D 1 three times, by D 1.50 five times, and by D 2 once. The average change was D 0.6, and in more than two thirds of the instances, or twenty-one out of thirty, the refraction either remained unaltered or did not diminish by more than D 0.50.

THE MECHANICAL TREATMENT OF DETACHED RETINA.—Grossmann (*Ibid.*) reports three cases of detachment of the retina treated by aspiration of the subretinal fluid and injection of a few drops of a neutral fluid into the vitreous. He used a very

fine hypodermic syringe to aspirate the effused subretinal fluid, and he raised the intra-ocular pressure by injecting a 0.75-per-cent. solution of common salt, followed by a tight compressive bandage. The results were satisfactory enough to lead to further trials. The first case was in a lad of eighteen years, who had a moderately large detachment below and to the inner side of the optic disc, resulting from a blow six months before. The refraction was emmetropic. The second case was in a young man of twenty-five years of age, who had received a severe blow on the head by falling down stairs three months before, and had a shallow but extensive detachment of the retina in the lower part of the right eye, the other eye being normal. The third case was in a woman, aged thirty, who had a large, not very deep detachment, extending over the greater part of the lower half of the right eye, which had lasted as long as she could remember. The refraction was myopic D 3, and there was a small posterior staphyloma in each eye, with central vision that with sph.-D 3 was nearly normal. In all three cases the results obtained were, as far as the replacement of the retina went, highly satisfactory. Functional improvement was small in two cases and absent in the third. This was due only to the changes which had already taken place in the structure of the detached retina.

THE ACTION OF CONTINUOUS ELECTRIC CURRENTS APPLIED IN THE VICINITY OF THE BRAIN, AND ESPECIALLY ON THE EYE.—Gillet de Grandmont ("Recueil d'ophtalmologie," July, 1883) has an interesting article upon this subject. His manner of applying the current is as follows: The rheophores are formed of carbon discs from gas-retorts, covered by chamois-skin. The negative pole is placed below the orbit in the course of the infra-orbital nerve, or in the vicinity of this nerve. The positive pole is placed on the neck behind the angle of the lower jaw, about in the region of the superior cervical ganglion. He avoids producing phosphenes by keeping the rheophores immovable; and the current is never allowed to pass more than four or five minutes, owing to the great difficulty hitherto experienced in affirming any notable increase in caliber of the choroidal and retinal vessels, either in rabbits or man, after the passage of a current from twenty-four cells for half an hour through the eyes, as well as in demonstrating any contraction of the pupil. Gillet de Grandmont was forced to invent the instrument which he describes under the name of the ocular thermometer. It consists of a flat basin or cistern, so curved as to lie conveniently in the inferior conjunctival cul-de-sac without causing any pain to the patient. The stem is divided into tenths of a degree. This instrument is of very great sensitiveness, and admits of proving the depression of the ocular temperature in man after the application of the continuous current. This lowering of the temperature has always been from two to six tenths of a degree. The subjective sensations or phosphenes are the more luminous the less alteration the retina has undergone. In cases of long-continued amaurosis, it is with difficulty that a sensation of pale light is obtained. Another phenomenon to be noted is the metallic taste in the mouth. Occasionally a sense of giddiness is observed.

CATARHIAL CONJUNCTIVITIS WITH CONJECTIVE ARTHRITIS.—Robert (*Ibid.*) reports a series of observations on cases of catarrhal conjunctivitis occurring with or followed by arthritic inflammation. The conjunctival inflammation was characterized by oedematous swelling and a purplish discoloration of the eyelids; a muco-purulent discharge from between their edges; intense congestion of the entire conjunctiva; chemosis; continual lachrymation; lancinating pain, and photophobia. The cornea remained intact throughout. After some days of treatment this conjunctivitis seems to terminate favorably, but in a day or two inflammatory symptoms appear in one or more joints,

eventually become localized in some one joint, and resemble very much blephorrhagic arthritis. He has noticed the combination of diseases very often in young soldiers. He thinks the disease a complex catarrhal affection, which is developed under special atmospheric conditions.

THE PURSE-OR POUCH-SUTURE OF VON WECKER, APPLIED TO THE ABLATION OF STAPHYLOMATA AND TO ENUCLEATION.—Masseton ("Klin. Monatsbl. f. Augenheilk.," September, 1883; "Annales d'oculistique," July-August, 1883) recommends the employment of the pouch-suture invented by Wecker in cases where a corneal staphyloma requires removal, or where enucleation is necessary. It consists essentially in forming with the neighboring conjunctiva detached from the corneal margin, and with the sub-conjunctival tissue, a sort of cap or hood which is attached by sutures in front of the scleral opening. The flexibility of the mucous membrane and its readiness to fall into folds admit of a perfect union, although the wound is a circular one. The first step in this operation is to pass through or across the detached conjunctiva four sutures of different colors, turning or reversing the loops, two by two, over the bridge of the nose and the temple; then the staphyloma is to be removed. The technique of the operation is as follows: After the conjunctiva has been dissected up all around the cornea for the distance of a centimetre, so as to obtain a uniform and resisting hood or cap, the conjunctiva is seized beyond and above the horizontal diameter of the eyeball, at a point two or three millimetres from its detached border, and a needle armed with a disinfected silk suture is passed through it. Then, at a distance of four or five millimetres from each other, successive folds of the conjunctiva are transfixed. Thus, in following around the detached border of the conjunctiva, a point is reached just below the horizontal diameter of the eyeball; here the needle is withdrawn. This for the left eye. If it is the right eye, the border of the detached conjunctiva is followed in the reverse direction. Then remove the staphyloma, guarding carefully the circular suture. Next draw the suture tight and tie it; this produces a sort of knot or excrescence at the center formed by the folds of the conjunctiva. The latter, together with the sub-conjunctival tissue, gives a very resisting covering which will cover over solidly large losses of substance, and prevents all loss of vitreous humor. As soon as the wound is sufficiently consolidated the suture is withdrawn. This operation has, in Wecker's hands, succeeded admirably after enucleation also.

A REFRACTION OPHTHALMOSCOPE.—Guérin ("Annales d'oculistique," July-August, 1883), manager of the optical establishment of Roulot, in Paris, has recently constructed a refraction ophthalmoscope, in which the wheels or discs are moved by a system of escapement and detent or expansion, which is an entirely new method for these instruments. The instrument is composed of two wheels or discs superimposed the one upon the other, one carrying concave glasses, the other carrying convex glasses. They are entirely covered by screw-plates, not even their edges showing beyond the edges of the plates. In the lower part of the instrument are two buttons, one on each face or surface; pressure upon these from above downward causes a progressive series of glasses to pass before the eye; pressure from below upward gives the same series in an opposite direction. This ophthalmoscope, provided with mirrors and a magnifying glass, gives a series of sixteen convex glasses and twenty-seven concave glasses.

THE RELATIONS BETWEEN A VARIETY OF GRAVE KERATITIS AND ASTIGMATISM OF THE CORNEA.—Martin (*Ibid.*) presents a paper upon this subject which has some points of interest. In all the cases examined, the anomaly existed in both eyes and to about the same degree. If there was a difference, the most astigmatic eye was always and sometimes the sole seat of kera-

titis. In the genesis of this variety of keratitis astigmatism plays a dominant part, while the serofulous constitution only acts secondarily. Asymmetrical contractions of the ciliary muscle, in persons whose eyes are occupied with objects of small dimensions, especially in students whose accommodative power in proportion to their age is enormous, will eventually always give rise to disorders of circulation and nutrition of the eyeball, and especially in a membrane deprived of blood-vessels. This influence of accommodation is confirmed clinically, first, by the fact that local atropinization of both eyes with a strong solution is the most efficacious means of bringing about a cure in these cases; and, secondly, by the fact that the wearing of cylindrical glasses is almost certain to prevent a relapse of the disease whenever the accommodation continues to act in a way compensatory of the inequality in the refraction of the meridians. Martin proposes to call this disease "astigmatic keratitis." He formulates his conclusions as follows: 1. The cure of these cases of keratitis demands the paralysis of accommodation in both eyes. 2. Relapses will be avoided by the use of glasses which correct the error of refraction. 3. A first attack will be prevented, in cases of a certain grade of astigmatism, by the use of correcting glasses, which enable the patient to work with the least amount of accommodative fatigue. 4. Patients whose corneæ show lesions due to astigmatic keratitis will often find relief and an improvement of vision by wearing cylindrical glasses.

There are no characteristic lesions in this form of keratitis. Astigmatic keratitis is but a kind of pannus. Corneal pannus, which is the grave type of serofulous keratitis, very often at first presents no difference from pteryctenular keratitis, and both these forms of inflammation may give rise to the same complications.

HEMORRHAGE FOLLOWING THE EXTRACTION OF CATARACT.—Warlomont (*Ibid.*) reports a disastrous occurrence of this kind occurring in both eyes of the same patient, a woman aged sixty-three, and apparently in perfect health. The first operation was done on the left eye on April 9th, by a small lower flap with iridectomy. As soon as the capsule was incised the lens came forward into the wound and almost outside the eye. There was no loss of vitreous, and the lips of the corneal wound were in perfect coaptation. No anæsthetic had been used. Half an hour later nausea and vomiting came on, the bandages became soaked with blood, but the patient complained of nothing but a feeling of discomfort in the eye. On examination, the wound was found filled by a clot of blood which pressed the lips of the wound wide open. As the patient had descended a flight of stairs after the operation, it was thought that the disaster was probably due to this act of imprudence. The eye was entirely lost, and it was deemed advisable to enucleate at once. To this the patient consented, and it was done. The eye was hardened and examined microscopically by Dr. Van Duyse, who found that the hæmorrhage had come from the choroid. At first it was interstitial, but had soon become retro-choroidal, especially in the supero-anterior part of the eye. The intra-ocular membranes were dissected up and rolled down toward the bottom of the eye, and also forward toward the wound. To this was due the prolapse of the entire vitreous and detachment of the retina; to this, detachment of the choroid. The ciliary body was detached from above downward. There was total prolapse of the iris with the anterior capsule of the lens and remains of the lenticular cortex. The retina was normal. The vessels of the anterior part of the uveal tract were engorged with blood. The polygonal retino-choroidal epithelium was normal, and there was nothing found in the choroid to explain the hæmorrhage. The walls of the vessels were normal, there being neither hyaline, fatty, nor atheromatous degeneration. There were no degenerative changes of the choroidal elements so fre-

quently found in elderly persons. There was no histological change in the chorio-capillaris. Nothing was found to account for such a disastrous result of a cataract extraction. The operation upon the second eye was performed on July 16th by Lebrun, by a small median flap, and without an iridectomy. The operation was admirably done, but scarcely had the capsule been incised when the lens presented. The speculum was at once removed, and, as the lens passed out, the eyelids were at once closed by a compress held in the hand. After a few minutes the lids were opened, and the corneal wound was seen to be gaping widely from the intra-ocular pressure of the vitreous which had come forward but had not yet prolapsed. A pressure bandage was at once applied, iced compresses of cracked ice were ordered, and the patient was not allowed to be moved from the bed. Before Lebrun had left the building the bandage became stained with blood and the second eye was found to be lost in the same manner as the first. No explanation is offered of the result in this case.

LATERAL DISLOCATION OF THE LENS WITH SECONDARY GLAUCOMA; PATHOLOGY.—Priestley Smith ("Ophthalmic Review," September, 1883) reports a case of this kind occurring in a man, aged fifty, the results of a kick in the face. After describing the condition of the case, its treatment, and course, he takes up the pathology of the eye as found on examination after enucleation. The views of Hermann Schmidt and Becker proved in this particular case to be at fault. The lens was to all appearances firmly fixed in its new position and made no oscillations whatever, and the high tension which came on within a day or two of the accident, if not earlier, was entirely removed for the time being by a single application of eserine. The author's own opinion that partial dislocations of the lens induce glaucomatous complications by reason of the direct pressure of the periphery of the lens against the periphery of the iris throughout that portion of the circle toward which the lens is displaced, and consequent closure of the angle of the anterior chamber in this situation, was shown to be right in principle by the dissection in this case. But the idea of a direct pressure of the lens-margin upon the iris was wrong; the ciliary processes necessarily intervene. There are three points in the case which, taken in conjunction, clearly prove that the immediate and essential cause of the glaucoma was a mechanical obstruction: 1. The visible pushing forward of the iris at the side toward which the lens was displaced. 2. The complete reduction of the tension which ensued within an hour of the application of eserine to the eye. The only feasible explanation of this effect is a reopening of a closed outlet for the pent-up fluid; and the only conditions in which eserine has such a power are just those in which the outlet is closed by a displacement of the iris, reducible by contraction of the pupil. 3. The position of the lens, ciliary processes, and iris, revealed by dissection. If the lens were suspended in fluid merely, it could drive the ciliary processes forward or compress them only by reason of a momentum imparted to it by movements of the eye or head; if, however, it rested posteriorly against a consistent cushion, its pressure on the processes is readily explained. A vitreous body of normal consistence, or even a fluid vitreous, provided it be retained within its limiting membrane, affords such a cushion. From the fact that in the present instance the iris was not noticeably tremulous, that the lens did not alter its position during several months, and that no vitreous fluid escaped until after the iridectomy was safely completed and the eyelids closed, it is probable that the hyaloid membrane was actually unruptured until the moment when a profuse hemorrhage from the choroid forced the vitreous through it. While asserting the obstructive origin of the high tension in the present case, the author does not deny that inflammation and perverted secretion

may also play a part in such glaucomatous conditions. There were, doubtless, some inflammatory conditions in this eye, and these, in process of time, would very probably have sealed up the outlet of the anterior chamber by solid adhesions, and there were traces of an albuminous secretion from the ciliary processes. It was, perhaps, owing to such changes that eserine soon lost its power of contracting the pupil and reducing the tension.

THE PATHOLOGICAL ANATOMY OF FOLLICULAR INFLAMMATION OF THE CONJUNCTIVA, OR TRACHOMA.—Raehlmann ("Arch. f. Ophthalmologie," xxix, 2) has a very voluminous paper upon this subject considered under numerous heads. In the first stage of their existence, Raehlmann finds that the follicles possess an envelope, formed by the peculiar shape of the cells which form the periphery of the follicle. While in many cases the limiting fiber-layer, in consequence of further growth, is developed anteriorly and the fibrous ring is closed, in other cases there is no such formation, since the follicle either perforates outward, or, in consequence of secondary metamorphoses, loses its peculiar shape and significance. The contents of the follicle may undergo softening, or become sterile in consequence of a process of induration. The older follicles, the contents of which have become partially or wholly softened, may easily be emptied by pressure into the conjunctival sac. In considering the tissue changes in the conjunctiva, in the immediate vicinity of the trachoma-follicle, Raehlmann mentions single or numerous follicular ulcers on the surface of the conjunctiva, and in this way the mucous membrane may be destroyed over a large surface and changed into fibrous connective tissue. In a fresh case of trachoma the follicles are sometimes so densely crowded together that their configuration is altered and they are laterally flattened and apparently run together, empty themselves, and their walls collapse. Eventually the conjunctiva loses entirely its quality of secreting membrane. Hence trachoma may be defined as a follicular, ulcerative inflammation, which ultimately destroys the adenoid tissue of the conjunctiva. In new-born children there are neither gutters nor furrows nor adenoid tissue present, and the conjunctival surface is smooth. With the appearance of the adenoid layer, which grows in some places faster, in others slower, appear also the pseudo-papillæ of the conjunctiva as well as the ridges or crests, between which lie the furrows and gutters. Communicating laterally with the systems of grooves and furrows are fissures in the epithelial layer. As a consequence of an increase in volume of the membrane, deep folds appear, which bring into view the before-mentioned fissures, which may extend through the entire thickness of the conjunctiva. By means of the ulceration the walls of these fissures may grow together partially or entirely, and thus peculiar glandular divisions arise in them. The solid epithelial depressions, deep in the membrane in pure trachoma, only signify regenerative proliferation of the epithelium for the purpose of covering up losses of substance from ulceration and excoriation. Follicular formation in the conjunctiva is not only not without analogy, but, from reasons of analogy, it is made in the highest degree probable, by perfectly similar new formations observed and demonstrated time and again in other mucous membranes. In regard to certain anatomical formations in chronic blepharitis, the newly formed fibrillæ are usually fine, delicate, and without sclerosis. Raehlmann has never seen the conjunctiva much thickened even after the most intense blepharitis, and even in cases where the entire conjunctival sac consisted of connective tissue the cicatricial layer was relatively thin. Although the cicatricial conjunctiva, after blepharitis, may be shrunken and thinned throughout, it still may be made to glide to a moderate degree over the tarsus and very easily in the retro-tarsal fold, which can never be done with the trachoma-

tous conjunctiva. The cicatrix remaining after blennorrhœa is more a superficial cicatrix, more spread out, while the trachomatous cicatrix is more like a typical layer, generally a radiating shape with the greatest extent or diameter along the edge of the lid, with a tendency to retract toward the tarsus. The little vesicular formations on the surface of the conjunctiva found in follicular catarrh are also met with very often in almost healthy mucous membranes, and may exist for years unchanged and without giving rise to any peculiar symptoms. At the beginning of the cicatricial stage there lies upon the inner surface of the tarsus a thick layer of young connective tissue, which may be four or five times as thick as the normal conjunctiva. This young connective tissue becomes the seat of sclerosis and cicatricial retraction. As this lies directly upon the tarsus, without being separated from it by a loose, ductile layer, and is as it were adherent to it, whenever cicatricial retraction occurs it must lead to curvature of the tarsus.

THE COMPARATIVE ANATOMY OF THE LAMINA CRIBROSA OF THE OPTIC NERVE AND ITS IMMEDIATE VICINITY.—Hoffmann (*Ibid.*) sums up his investigations into the comparative anatomy of the lamina cribrosa as follows: 1. The basis of the lamina cribrosa is a vascular network, which is present in all vertebrates. 2. This is everywhere formed of a vascular circle, which arises either in the sclera or choroid, or in the pia, and is analogous to the vascular circle of Zinn, from which it is seen that the lamina seems to be at times a scleral formation, and at times a choroidal or pio-choroidal formation. 3. A connective-tissue network, formed like the vascular network, always accompanies the latter, in the most varied degrees of development, from the marked development met with in the horse down to the merest trace, as found in the hare, elephant, and lower animals. 4. Regular peripheral vessels of large size, branches of the posterior short ciliary arteries, contribute to the nutrition of the optic nerve and retina, which admit of the recognition of the anatomical substratum of the cilio-retinal vessels and anastomose with the central vessels. 5. The vessels above mentioned increase considerably in number when the central vessels are but slightly developed.

THE RATIO OF MAGNITUDE OF AFTER-IMAGES WITH CLOSED EYELIDS.—Mayerhausen (*Ibid.*) gives the following results of his investigations into this subject: 1. With closed lids, the diameter of the after-image appears the greater the less the distance of the observed object is. 2. The entoptic after-images of objects of different size bear the same proportion to each other for all distances of the object of fixation as the sizes of the objects to each other. 3. When the object of fixation is at a distance of two metres, the entoptic after-image equals the size of the object. 4. With the object of fixation at thirty centimetres, the entoptic after-image has about double the diameter of the object. 5. The increase in size of the entoptic after-images is not the same for all distances of the object of fixation; it is, the smallest between the objects of fixation at two and three metres; from here increases progressively in both directions, and increases very rapidly with slight changes in the distance of fixation. 6. The apparent distance of the entoptic after-image for fixation at one and two metres is about equal to the distance of the object, but for all other distances of fixation it is greater than the latter. 7. The size of the object of fixation in itself exerts no influence upon the apparent distance of the entoptic after-image. 8. The apparent distance is the smaller the greater the entoptic after-image appears, and *vice versa*; the former depends upon a secondary decision or opinion. 9. These apparent distances hence by no means correspond to the distances which may be reckoned from the occasional measurements or diameters of after-images for ectopic observation. 10. It may be discerned that, in the waking condition

and with closed lids, when, for a certain time, all voluntary movements are excluded, the ocular axes are directed toward a point which in different individuals is probably not situated at exactly the same distance of about two metres; this condition or state must be regarded as a sort of position of equilibrium. 11. After fixation for any or all other distances, when the lids are closed and voluntary movements are not carried out, the visual axes do not immediately fall back into the above-mentioned position of equilibrium, but remain fixed at or directed toward a point situated on one side or the other of the distance of position of equilibrium, by reason of a still existing state of contraction of the muscles in question. This point lies removed in both directions so much the farther from a point about two metres the greater the convergence or relative divergence was which immediately preceded it. 12. The entoptic after-image most probably always lies in the point of decussation or convergence of the visual axes; its linear magnitude is equal to the distance assumed by the visual axes after cessation of the voluntary object-fixation, divided by the actual distance of fixation of the object, the diameter of the latter being made equal to 1.

INTRA-OCULAR TENSION.—Holtzke's (*Ibid.*) manometrical experiments have yielded him the following results: 1. With the dilatation of the pupil caused by atropia there is intimately connected an increase of the tension in the anterior chamber; and with the contraction of the pupil induced by eserine there goes hand-in-hand a diminution of this tension. 2. Eserine possesses the power of increasing the intra-ocular tension to a considerable degree; but the myosis caused by eserine not only counteracts this power of increasing the tension, but also lowers this tension below the physiological average. 3. Atropine certainly does not possess the power of directly increasing the tension, but it increases the tension in the anterior chamber considerably by its power of dilating the pupil. 4. Under physiological conditions, without the employment of atropine or eserine, the tension in the chamber rises with dilatation of the pupil, and sinks with contraction of the pupil.

MALAXATION (MASSAGE) OF THE EYE AFTER SCLEROTOMY.—Dianoux ("Archives d'ophtalmologie," Sept.-Oct., 1883) has a short paper upon this subject which is of some interest. The isolated cicatrization and definite independence of the lips of the wound are due to the excess of pressure upon them; and it is to the excess of pressure artificially produced that we should appeal to realize similar sanitary conditions in cases of sclerotomy. He advises, on the evening following the operation, that the surgeon should make a series of pressure movements on the eyeball with the ends of the index-fingers, in order to separate the lips of the wound, and thus evacuate a portion of the aqueous humor. If this manœuvre is repeated morning and evening for five or six days, but slight pressure is needed to cause an exudation of the aqueous humor at the angles of the scleral wound, which lifts up the conjunctiva, and thus the tension of the eyeball is diminished. This manœuvre is very well borne by the patients, who soon learn to do it themselves. The massage, as executed by Pagenstecher, does not suffice to cause a gaping of the lips of the wound, and hence he recommends this method of malaxation of the eyeball as more efficacious.

Miscellany.

THERAPEUTICAL NOTES.—*Stigmata Maidis* in the Treatment of Diseases of the Heart.—Dr. Henri Dupont has made use of this drug in cardiac affections, and has recorded his impressions of its action as compared with that of digitalis and convallaria ("Union médicale,"

February 21, 1884). In the trials he has made of it during a period of three years he has been struck with three facts: diuresis, slowing of the heart's action, with improved rhythm, and the tolerance of the drug shown by the system. The diuretic action is almost always manifested at the very first, and goes on increasing up to the thirteenth or fourteenth day; and it is in cardiac affections, with edema of the lower limbs or general dropsy, that the beneficial action of the agent is the most prompt and the most evident. While the dropsy diminishes and often disappears, the arterial tension increases and the venous tension is reduced concurrently, the general condition becomes decidedly improved, and, in particular, the author mentions a subjective feeling of calmness and *bien-être*, except where there is pronounced dyspnea. The latter symptom he has never known to be relieved. In hypertrophy, however, and stenoses, the result has almost invariably been excellent. On the whole, the author thinks the stigmata act more powerfully than digitalis, and with about the same energy as convallaria, but that they are to be preferred on account of their not producing the unpleasant effects that sometimes follow the use of either of the latter drugs. The extract is the preparation always employed by Dr. Dupont; never more than three grammes a day. The strength of the extract is not stated. He is guided as to the dose by the amount of diuresis—only enough need be given to produce free action of the kidneys.

The Heucheloup Mineral Waters.—In a recent number of the "Union médicale," Dr. Paul Labarthe gives the following analysis of these waters:

One litre contains :	Grammes.
Free carbonic acid	0.0413
Sulphate of calcium	1.3887
Sulphate of magnesium	0.1640
Sulphate of sodium	0.5356
Sulphate of potassium	0.0267
Sulphate of strontium	0.0044
Sulphate of lithium	} Traces.
Sulphate of ammonium	
Bicarbonate of calcium	0.3030
Bicarbonate of protoxide of iron	0.0020
Chloride of sodium	0.0068
Phosphate of calcium	Traces.
Silicate of aluminium	0.0220
Total	2.4345

The waters are highly recommended for calculous affections, particularly of the phosphatic variety.

Devotion of Lemon in the Treatment of Miasmatic Fevers.—Dr. Magleiri ("Siglo Médico," November 11, 1883; "Bull. gén. de thérap.," February 15, 1884) gives a very encouraging account of his success in substituting this cheap remedy for quinine in the treatment of the fevers endemic in a highly malarious region. It acted satisfactorily in seventy-two per cent. of the cases. Its action, he remarks, is somewhat slower than that of quinine, and it should not be depended upon in severe cases.

Chlorate of Potassium in Acute Cystitis.—Dr. E. Boegehold ("Deutsche med. Wochenschr.," 35, 1883; "Centralbl. f. d. ges. Therapie," October, 1883) recommends the use of a ten-per-cent. solution of chlorate of potassium internally, in doses of a tablespoonful every two hours. Injections of a three-per-cent. solution into the bladder are said to give very good results in severe cases, but the pain occasioned by the introduction of the nozzle is so great that patients will seldom consent to undergo the treatment.

Veratrine in the Pruritus of the Menopause.—Dr. J. Cheron ("Revue méd.-chir. des mal. des femmes"; "Progrès méd.," February 23, 1884), after remarking upon the obstinacy of pruritic affections at the time of the menopause, no matter what their cause may be, states that veratrine is peculiarly useful, in the form of an ointment:

Veratrine	0.15;
Lard	30.00.

A piece as big as a pea is to be applied to the itching part. When the pruritus is general, the remedy should be given internally. Two centi-

grammes may be made into forty pills with powdered licorice, and from two to six of these pills may be given daily. Not more than one should ever be taken at one time, however, and the increase of dose should be gradual.

PHENIC ACID.—A correspondent writes that, in his opinion, the trials that have been made with chemically pure phenic acid and its preparations by prominent physicians in New York, Chicago, St. Louis, and other large cities, in hospital and private practice, deserve more attention than they have received, for in many cases where an internal antiseptic seemed to be indicated, to destroy disease germs by direct attack, the use of these preparations has met with brilliant success. The best carbolic acid of our chemists being pronounced not to be chemically pure, he thinks it is unsafe, and therefore that only those preparations that have for their basis the pure phenic acid obtained by the process of Dr. Déclat, as set forth in his "Traité de l'acide phénique," should be used, which was the case in the experimental trials to which he alludes.

The pure acid always crystallizes in long, needle-shaped crystals; never in masses. It has no action on litmus paper, and it is soluble in distilled water in the proportion of six per cent. A specimen which does not stand these tests is not chemically pure. In its pure state it changes readily on exposure to moisture, air, and light. This change can be prevented by combining it, atom for atom, with syrup or glycerin. When taken internally in either of these combinations, it resumes its nascent condition so soon as the processes of digestion and absorption free it from its combination. Being then readily diffusible, it permeates the system, performing its germicide work on the way, and passes off principally by the lungs and the skin, but a slight amount being eliminated by the kidneys.

In addition to its principal action as a germicide, there are two minor effects that claim attention. One is that it has a tendency to cause constipation, which can easily be obviated by a light laxative, if necessary. The other is that, to a very slight degree, it diminishes the fluidity of the blood. In many cases, especially those of chronic disease, these effects may not be objectionable; however, the tendency of phenic acid to diminish the fluidity of the blood can be counteracted by the use of an ammonium-phenate combination, which facilitates the circulation by keeping the blood fluid, at the same time stimulating the nervous system and acting as an excellent antipyretic.

The writer considers that phenic acid is indicated in a number of slight ailments, in malarial affections, in scarlatina, and in many chronic diseases. Whenever fever is present, as in the zymotic diseases, the combination with ammonium should be used, alone or alternately, with the simple acid. The compound with sulphur is indicated for chronic diseases, such as bronchitis, catarrh, skin diseases, etc.; that with elementary iodine and that with iodide of potassium for glandular enlargements, scrofula, syphilitic cephalalgia, ostealgia, etc. Hypodermic injections of the various preparations should be resorted to where a more rapid and profound effect is needed, whether in adults or in children. In many cases both methods should be used. The details should all be managed according to the features of the individual case.

TRANSFUSION AS A HEMOSTATIC.—The Paris correspondent of the "British Medical Journal" (February 23, 1884) says: M. Hayem, at the meeting of the Société Médicale des Hôpitaux, on January 26th, made a communication concerning transfusion as a hemostatic. He considers transfusion a valuable hemostatic agent, but does not recommend it in advanced cachectic conditions. Transfusion was practiced in his wards on a patient suffering from pernicious anemia; plegmasia alba dolens immediately appeared; first one limb was affected, afterward the other. The transfusion might have been the cause.

THE VIRUS OF HYDROPHOBIA.—M. Pasteur made an interesting communication to the Paris Academy of Sciences, on February 26th, in relation to canine madness. He stated that the disease could be communicated to a dog by inoculation with fragments of marrow or of nerve taken from a mad dog. He also stated that he had rendered twenty dogs proof against the disease by inoculating them with a modified virus.—*British Medical Journal*.

Original Communications.

THE TREATMENT OF FRACTURES OF THE PATELLA BY THE PLASTER-OF-PARIS SPLINT.*

By JAMES L. LITTLE, M. D.,

PROFESSOR OF CLINICAL AND OPERATIVE SURGERY IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; PROFESSOR OF SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF VERMONT.

IN presenting this subject to the society this evening, I wish to describe the method of treating simple transverse fractures of the patella with plaster of Paris, which I have used since 1863, and which has never before been described. I am also anxious that it shall serve to draw out a full discussion upon the treatment of this important injury.

The plaster-of-Paris *bandage* has been more frequently used, and the results have not been sufficiently satisfactory to prevent Hamilton from condemning it in these words: "Plaster of Paris is, of all the forms of immovable dressings, the worst, because it is the heaviest; but of them all it must be said that they are necessarily cumbersome as a form of portable apparatus; they are to some extent dangerous, especially in the hands of inexperienced surgeons; they are inefficient as a means of approximating the fragments; they actually serve but one single purpose, namely, to keep the limb straight; and this they do too effectually in many cases, causing an unnecessary degree of passive ankylosis. The limb can be maintained in a straight position by a much simpler and lighter dressing than a plaster-of-Paris splint, and by means which permit it to be daily examined and the condition of the fragments noted and corrected, and which will allow slight passive motion occasionally to the knee joint, a practice which has been found in my experience perfectly safe, and useful in some measure, as far as the ankylosis is concerned. In short, to apply the plaster of Paris, and permit the patient to go about on crutches, as is generally acknowledged by its advocates, is to abandon, practically, every acknowledged indication of treatment except straightening the limb and securing immobility at the knee joint."†

This criticism from so high an authority has evidently been drawn out by his observation on the treatment of the fracture in question by the plaster-of-Paris *bandage*. It will perhaps be best for me to state at the outset, in order to avoid a misunderstanding, that I always make a distinction between the plaster-of-Paris *bandage* and the plaster-of-Paris *splint*—two entirely different methods of using this material. The method which I propose to describe is by the use of the plaster-of-Paris splint, which was first introduced by me in 1861, and was first applied to a fracture of the patella in 1863 in a patient of the late Dr. Tucker, of this city, and which I have used in all the cases that have come under my

care in St. Luke's and St. Vincent's Hospitals, as well as in my private practice.

Immediately after the receipt of the injury I elevate the limb slightly and place it on a pillow or a single-inclined plane, and wait until the swelling and inflammatory action which follow have subsided. The limb is placed in this position simply for the comfort of the patient, and not for the purpose of relaxing the quadriceps extensor muscle, and thus preventing the separation of the fragments, which was formerly considered necessary. Although I have often attempted, I have never been able to demonstrate that it made any appreciable difference in regard to the separation of the fragments whether the limb was in a straight position or with the thigh flexed on the pelvis.

Sometimes, when the effusion into the synovial cavity is great, I apply pressure, as soon as the patient is able to bear it, by means of a bandage. When the swelling has subsided, which takes from five days to a week, the following dressing is applied: A posterior splint is made of two thicknesses of bleached Canton flannel, strengthened in the middle, under the knee, by two extra layers; this is made long enough to reach from a little above the ankle to above the middle of the thigh, and wide enough to cover two thirds of the circumference of the limb above and below the joint, but at the joint it should only just cover the condyles of the femur. Two pieces of Canton flannel, from two and a half to three inches in width, double thickness, one long enough to nearly encircle the limb at the ankle, the other to encircle it at the upper third of the thigh, are prepared at the same time. The pieces designed for the posterior splint are then thoroughly saturated in a mixture of plaster of Paris and water, taking care that the mixture is not too thick,* and then smoothed out upon a board with the hand and applied smoothly to the limb. Then the two bands are prepared in the same way and applied around the upper and lower extremities to hold it in position. A dry roller bandage is then firmly applied over all, and the plaster allowed to set.

As soon as this is accomplished the bandage is removed and we have a firm posterior splint, secured above and below by transverse bands.† Two other strips of a double thickness of Canton flannel, an inch wide, and long enough to overlap on the posterior surface of the splint, are saturated in a fresh mixture of plaster of Paris and then tightly applied above and below the patella, while the fragments are held in position by an assistant, in the same manner as adhesive straps are used for coaptation in this fracture. A dry roller bandage is then rapidly applied with the figure-of-eight turns over the strips. The surgeon then, with thumb and finger of each hand over these coaptation bands, forces the fragments into close approximation,‡ and holds them

* Superfine or dental plaster should be obtained. The mixture should be of about the consistence of cream.

† Sometimes I apply a third band between the knee and the lower one.

‡ The lower coaptation band holds the lower fragment fixed, and at the same time enables the surgeon to make counter-pressure while he forces the upper fragment into position.

* Read before the New York Surgical Society, March 11, 1884.

† "A Practical Treatise on Fractures and Dislocations," by Frank H. Hamilton, M. D., 1880, p. 522.

there until the plaster has set. The bandage is then removed and a fresh one applied over the whole length of the

FIG. 1.

limb.* The dressing is then complete. Fig. 2 shows the splint with the bandage removed.

FIG. 2.

It is a good plan for the surgeon, before applying the coaptation bands, to see that the fragments can be easily approximated. In a number of cases I have found some difficulty in keeping the fragments in the same plane, or in preventing them from tilting, there being a tendency for one to rise above the other. This can be overcome by making pressure with the fingers over the line of fracture while waiting for the bands to harden.

This dressing differs essentially from all others, in that the fragments are adjusted by the hands of the surgeon, and the "setting" of the plaster keeps them in the exact position in which they were held.

With this dressing the patient is not compelled to keep his bed, but may sit up or go about on crutches with but little inconvenience.

This apparatus, like all plaster-of-Paris splints, should be applied directly against the skin, care being taken, however, to remove the hair, or else smear the limb with vaseline or oil.

The condition of the fragments can now be examined at any time by simply removing the bandage, and, in case any separation has taken place in consequence of the shrinkage of the limb, it can be corrected by removing the coaptation bands and applying new ones; care should be taken, if this becomes necessary, which is seldom the case, to moisten the posterior splint in order to insure the adherence of the new pieces.

This overcomes one of the objections urged by Dr. Hamilton, the inefficiency of this dressing as a means of approximating the fragments. Another objection which he makes, in regard to the weight of the splint, is not at all applicable, as patients have never complained of this, and I doubt

very much if it weighs any more than the apparatus he recommends.

Pressure sores have never been produced in my experience, nor have the patients ever complained of any pain caused by undue tightness of the dressing. In fact, constriction of the limb by the splint, bands, or bandages, so as to interfere with the circulation, can not occur, even in inexperienced hands. In this respect it is safer than the plaster-of-Paris bandage which Hamilton so justly condemns.

In order to prevent a rough edge at the upper and lower extremities of the splint, it is advisable to fold them over about half an inch, thus bringing a perfectly smooth edge in contact with the soft parts.

This dressing should be left on for from six to eight weeks. The majority of patients rarely have any appreciable separation of the fragments at the end of the treatment, but, as the union is generally ligamentous, a certain amount of separation will take place in time, as in all cases where there is not bony union.

A case that I treated ten years ago by this method came under my notice again a few weeks ago; the fragments, which after the treatment were almost in direct contact, I found had only separated a little more than half an inch.

Two cases treated by this apparatus at St. Vincent's Hospital resulted in bony union. The first case, that of a man about forty years of age, was treated for a transverse fracture of the right patella. After the apparatus was removed, no separation or motion of the fragments could be detected. He remained in the hospital about three months. Six weeks after he left he was brought back with a severe injury of the head, from which he died. The patella was removed, and was found to have

FIG. 3.

FIG. 4.

united by bone. The specimen, which I show the society, has been carefully examined, by section, by Professor W. H. Welch, of the Bellevue Hospital Medical College, and he states that it shows true bony union. The line of fracture is slightly oblique from above downward and outward. The lower fragment is somewhat tilted, and overlaps the upper a little; it is also displaced outward one quarter of an inch. This interesting specimen belongs to the late Professor James R. Wood's collection in the Bellevue Hospital Museum.

In the second case, treated by Professor F. S. Dennis, although the patient was eighty-six years of age, no sepa-

* I have sometimes applied a plaster-of-Paris bandage over the splint. This makes a very strong dressing, but it prevents the inspection of the fragments during the course of the treatment. For this reason I prefer the dry muslin bandage.

ration or movement of the fragments could be detected when he left the hospital.

In comparing this method with the one of wiring the patella in simple fractures, under antiseptic precautions, which has lately come into vogue, I am inclined to give the preference to the one just described, or to any other form of dressing which results in close ligamentous union. The patient is not submitted to a surgical operation, which may endanger his life or the usefulness of his knee joint; for, with the utmost care in antiseptic measures, there is still the possibility of serious complications.

I think all surgeons will agree that a moderate amount of separation of the fragments by a ligamentous band does not in any way interfere with the usefulness of the limb. Hamilton says that, "if the ligamentous band is not more than an inch in length, the use of the limb is not impaired." In a case which I presented at one of the meetings of the society about two years ago, a patient, aged twenty-two, broke his patella transversely below its middle. He was treated by me in St. Luke's Hospital, and was discharged with a ligamentous union of less than half an inch. Six months after, he slipped in walking, and fractured the same patella about half an inch above the first fracture; this also united by ligament. In this case the ligament proved itself stronger than the original bone.

If, then, ligamentous union of a moderate length does not impair the usefulness of the limb, and is as strong as, if not stronger than, the original bone, why should we submit the patient to any serious danger in order to obtain bony union, which at the best is of questionable utility?

While bony union, obtained by wiring, may be the goal for which the idealist strives, I question whether it can ever be conscientiously adopted by conservative surgeons.

MILK DIET IN CHILDHOOD.

By D. M. CAMMANN, M. D.,

VISITING PHYSICIAN TO THE ORPHANS' HOME AND ASYLUM.

THAT milk is the only proper food for infants is universally acknowledged. It is my purpose to consider in the following paper whether the exclusion of meat from the dietary of children under seven or eight years of age and the use of milk as the chief article of food are beneficial. The importance of the subject can scarcely be overestimated. Upon the proper nourishment of the child's body and the careful training of his digestive apparatus depend the good or ill health of the future man and, to a great extent, his ability to succeed in life's struggle.

Milk is now used in much larger quantities than formerly, not only by children, but also by adults. But a pretty general underestimation of its dietetic value still prevails even among those who use it abundantly. Milk contains all the elements necessary to the growth of the body, and is the natural food of the young of all the higher forms of animal life. "A distinguished chemist once remarked to me," says Sir William Jenner,* "Do not forget that a pint of milk contains as much solid animal matter as a full-sized mutton-chop."

It is unnecessary to give an analysis of the composition of milk. Such may be found in any work on dietetics. "Milk," says Pavy,* "is complete in itself. In it exists, besides the organic principles, all the inorganic matter, including both salines and water, that is needed."

"The action of milk," says another writer,† "is exceedingly analogous to that of the cereals, and the combination of the two appears to be the most perfect kind of food."

We might very naturally infer that such a diet would be the best for children. It is with an appreciation of this that the temporary teeth, which begin to loosen and fall out at about the sixth year, are called milk teeth. At this age, too, the delicate mucous membrane of the stomach is not adapted for the meat diet of adult life. Who has not noticed that feverishness and fretfulness, and stomach and intestinal disorders, are common among children who eat largely of meat? In France it is not uncommon to give meat to very young children.

"In France," says an English writer,‡ "children are often fed upon flesh meats when very young, but they are not so healthy as English, and mortality is greater." "My experience is," writes Dr. Clouston,* "that children who have the most neurotic temperaments and diatheses, and who show the greatest tendencies to instabilities of brain, are, as a rule, flesh-eaters, having a craving for animal food too often and in too great quantities. . . . And in such children I most thoroughly agree with Dr. Keith, who, in Edinburgh, for many years, has preached an anti-flesh crusade in the bringing up of all children up to eight or ten years of age. I believe that, by a proper diet and regimen more than in any other way, we can fight against and counteract inherited neurotic tendencies in children, and tide them safely over the periods of puberty and adolescence."

Another writer, after urging the necessity of giving children an abundance of milk, continues enthusiastically: "If this, or anything approaching this, were the rule instead of the exception, rickets in its manifold phases would be completely banished from this country, and a much higher standard of health and robustness would unquestionably prevail."|| The strapping gillie of the Scotch Highlands is brought up on oatmeal and milk, and he is "certainly not wanting in strength and muscular endurance. On the contrary, as every one will admit who has had to keep up with him in a hard day's deer-stalking, he is all wind and limb."^

During the past twenty-five years, in a large institution in this city, meat has been omitted from the dietary of children under eight years of age,† and it must be admitted that this has been long enough to test fully the value of the

diet adopted. It will be appropriate in this place to consider the dietary somewhat in detail. It will be given in full as adopted about a year ago by the Board of Managers. It is essentially the same as that adhered to for the past twenty-five years. The reason for formulating a new dietary was that some changes were about to be made in the management of the institution, and the Medical Board was therefore asked to state its views upon the subject. The report of the board contains the following: "The past records of the institution furnish such ample proof of the value of milk and vegetable food, and the exclusion of meat from the dietary of children under eight years of age, that the Medical Board sees every reason to adhere for the future, to the diet from which such good results have been reaped in the past."

DIETARY FOR CHILDREN UNDER EIGHT YEARS OF AGE,

From November 1st to May 1st.

Sunday, Tuesday, and Friday.—*Breakfast*.—Bread and milk.
Monday.—Oatmeal, steamed, and served hot with molasses.
Wednesday.—Hominy, steamed, and served hot with molasses.

Thursday.—Mush, hot, with milk and sugar.

Saturday.—Wheaten grits, hot, with milk and sugar.

Sunday.—*Dinner*.—Bread, milk, potatoes, cal bage, or pumpkin; sago or rice pudding. *Supper*.—Bread and milk.

Monday.—*Dinner*.—Bread, milk, eggs, potatoes, parsnips, or spinach. *Supper*.—Bread and milk, stewed prunes.

Tuesday.—*Dinner*.—Bread, chowder of salt codfish, potatoes, crackers and milk, cabbage sprouts, or tomatoes. *Supper*.—Corn-starch, with milk and sugar.

Wednesday.—*Dinner*.—Bread, milk, potatoes, onions, rice or bread pudding. *Supper*.—Bread and milk, stewed apples.

Thursday.—*Dinner*.—Bread, milk, eggs, potatoes, spinach. *Supper*.—Mush and molasses.

Friday.—*Dinner*.—Bean porridge, potatoes, parsnips, carrots, or turnips. *Supper*.—Bread and milk, stewed peaches.

Saturday.—*Dinner*.—Bread, milk, potatoes, cabbage, or onions; apple sauce. *Supper*.—Hominy, with milk and sugar.

From May 1st to November 1st.

Breakfast.—Bread and milk.

Sunday.—*Dinner*.—Bread, milk, potatoes, asparagus, or other fresh vegetables, salt bacon broiled, rice or sago pudding. *Supper*.—Bread and milk.

Monday.—*Dinner*.—Bread, milk, eggs, string-beans. *Supper*.—Bread and milk, dried apples stewed.

Tuesday.—*Dinner*.—Bread, chowder of salt codfish, potatoes, crackers and milk, tomatoes, fresh fruit. *Supper*.—Corn-starch, with milk and sugar.

Wednesday.—*Dinner*.—Bread, milk, salt bacon broiled, onions, rice or bread pudding. *Supper*.—Bread and milk, stewed peaches.

Thursday.—*Dinner*.—Bread, milk, eggs, potatoes, string-beans, fresh fruit. *Supper*.—Mush and molasses.

Friday.—*Dinner*.—Bean porridge or salt codfish, potatoes, tomatoes. *Supper*.—Bread and milk, stewed apples.

Saturday.—*Dinner*.—Bread, milk, potatoes, asparagus or other fresh vegetables, fruit. *Supper*.—Hominy, with milk and sugar.

The following fruits may be given: Strawberries, raspberries, peaches, pears, currants, blackberries, blueberries. No changes to be made in the dietary without the approval of the attending

physicians. The report is signed by the Medical Board, Dr. J. R. Leaming, consulting physician, and Dr. Janvrin, Dr. McQuesten, and Dr. Cammann, attending physicians.

I will now give in tabulated form the number of children in the institution, and the number of deaths occurring for the past twenty-five years: *

YEAR.	No. of inmates.	No. of deaths.	Cause of death.
1859.....	78	..	
1860.....	78	..	
1861.....	74	1	Membranous croup.
1862.....	88	..	
1863.....	
1864.....	124	4	1 Pneumonia. 1 Diphtheria. 2 Scarlet fever.
1865.....	139	5	1 Diphtheria. 1 Cholera infantum. 1 Diphtheritic croup. 1 Dysentery. 1 Consumption. The medical report says that the last was " unquestionably caused by hereditary predisposition, both parents having died of that disease."
1866.....	153	3	2 Sequelæ of measles. 1 Inflammation of the brain. Tabes mesenterica.
1867.....	158	1	
1868.....	145	..	
1869.....	
1870.....	153	..	
1871.....	147	..	
1872.....	137	..	
1873.....	
1874.....	147	..	
1875.....	150	..	
1876.....	149	3	1 Small-pox. 1 Typhoid fever, supervening upon remittent fever. 1 from sudden strangulation by gottre.
1877.....	165	..	
1878.....	
1879.....	138	1	Cardiac disease. He had disease of the heart when admitted.
1880.....	141	1	Pneumonia.
1881.....	136	1	Scarlet fever.
1882.....	149	..	

The medical reports have been usually short, and have not entered very fully into details. A few extracts, however, bearing upon the subject under consideration may be given. The report of 1862 says: "From the antecedents of these children, being orphans, we might expect more or less constitutional tendency to disease—and such indeed is the fact; yet their general health will compare favorably with those enjoying the luxuries of their own happy homes. We owe much to the superior sanitary regulations adopted here, the facilities for bathing, the pure air, and, more than all the rest, to the admirable bill of fare—plain, nutritious, bountiful, and yet unstimulating—well adapted to their age and wants."

It will be seen, by referring to the previous table, that five deaths occurred in 1865. During this year meat was added to the dietary of the children, but the old dietary was resumed at the end of the year.

During the year a great deal of sickness prevailed, mostly cases of diseases of the digestive organs. This may have been to some extent due to the sudden and marked

* Children are admitted from three to eight years of age, and are kept in the institution until twelve years old. The table includes all the children. Children over eight years old have meat three or four times a week with their dinner, and at those meals milk is omitted. Otherwise, the dietary is the same as for the younger children.

changes of weather experienced during the early months of that year, and the persistent high temperature prevailing through the summer months. Under the head of gastric derangements ninety-eight cases are reported, and only twenty-five cases under the same heading in the previous year. It is somewhat significant that this was the only year during which the children under eight years of age had a meat diet. The report for 1866 says: "The dietary, being founded upon principles having reference to the wants of the system at the tender age of most of the inmates, is, from that fact, of such a nature as to preclude most of the digestive derangements which are the fruitful sources of most of the more serious maladies."

The report of 1868 contains the following, which is only an echo of many similar reports in other years. It says that during the year there was "a very moderate share of the ordinary diseases usually prevalent in like institutions." The report of 1870 says: "This is not the place to enter into a disquisition upon the causes of sickness among children, but it will be observed that, although we have many very young children, no cases of convulsions, gastric fever, and intestino-spinal paralysis have occurred, for the reason that the chief cause has been avoided, viz.: the ingestion of unwholesome and (for their age) indigestible food, the diet of such consisting entirely of bread, milk, farinaceous food, and vegetables, no 'indulgent parent' being at hand to permit the bolting of meat and other substances unfitted for these stages of physiological development of their digestive organs." The report of 1873, after congratulating the Board of Managers on the few cases of sickness during the previous year, and the length of time that has elapsed since the last death, says: "Truly this is something unusual when we think of the number of children in the institution, and of their tender years. Too much credit, however, can not be given to the physician first connected with the Home, Dr. J. R. Leaming, and for the admirable rules which he established as to the diet of the children. To this one point we attribute in a great measure our exemption from serious sickness." The report of 1875 says: "When we consider that the inmates are the children of parents who themselves lived in crowded and ill-ventilated houses, whose subsistence was unwholesome and still more poorly prepared, we can only see and wonder at the remarkable health in which proper sanitary, hygienic, and dietary measures may result." The report of the Medical Board for 1876 says: "It is with feelings of great satisfaction that it now announces to you the continued good condition of all the inmates of the Home; this is especially satisfactory when we consider the debilitated condition of most of the children on their entrance into the institution. The majority are the descendants of those whose condition in life was so unfavorable to health that they are placed under our care already impregnated with the seeds of disease sown by vice and violation of all sanitary laws. . . . We should fail to do justice to the labors of our predecessors did we omit to acknowledge our indebtedness to them for their very perfect dietetic and hygienic system heretofore established, and still continued with such favorable results."

The rarity of disturbances of the digestive organs has

been especially worthy of remark. Diarrhœa and dysentery in the summer months are rare. For twenty-five years only one death has occurred from dysentery and one from cholera infantum, and these were in 1865, when meat was for a short time added to the dietary. During this year the cases of derangement of the digestive organs were increased nearly three hundred per cent. over the previous year. Another matter worthy of note is the large percentage of recoveries from diseases which from time to time have invaded the Home. More than once has scarlet fever attacked a considerable number of the inmates, yet only two deaths have occurred from this cause in a quarter of a century. The general health and appearance of the children are exceptionally good. They are freer than is usual from colds and other slight ailments so common in the winter.

It has been my endeavor in this paper to avoid theorizing and to give a plain statement of facts, backed by twenty-five years of proof. I think that the experience gained during these years has shown not only that young children can do without meat, but that they become stronger and develop best without it; that they may thus escape many of the disturbances of the digestive organs and other troubles springing therefrom which are so common in childhood. Especially is the diet suitable in our country, where disturbances of the nervous system, both inherited and acquired, are so common. Many men and women doubtless owe to-day good health and success, and even life itself, to its happy influence in early years.

THE ARCHITECTURE OF THE SPINAL CORD,

AND ITS RELATIONS TO MEDICINE.*

By AMBROSE L. RANNEY, M. D.,

PROFESSOR OF APPLIED ANATOMY IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

THE spinal cord comprises that part of our central nervous system which is contained within the canal of the vertebral column. It is continuous with the medulla oblongata. It may be said to commence at the point where the fibers of the anterior pyramids of the medulla oblongata begin to decussate (which point corresponds to the upper border of the atlas), and to terminate at the lower border of the first lumbar vertebra.†

In the fœtus, during its development, and in the new-born child, the spinal cord extends throughout nearly the entire length of the vertebral canal. As the vertebral column increases in length with age, the cord does not grow proportionately; hence, in the adult, the lower end of the cord reaches the body of the first or second lumbar vertebra, and the cauda equina fills the remaining part of the spinal canal.

The circumferential measurement of the spinal cord is about one inch. At its largest part this measurement is exceeded by about two lines (one sixth of an inch).

* This article covers a series of lectures delivered by the author before a class of post-graduate students in medicine.

† Fehst ("Cent. für d. med. Wiss.," 1874) asserts that the spinal cord in women reaches to the lower level of the second lumbar vertebra.

tends from the lower part of the eleventh dorsal to the lower border of the twelfth dorsal vertebra, and is widest from before backward.* The shape of a transverse section of the cord varies with the level at which the section is made. In the dorsal region it is nearly circular; in the cervical and lumbar enlargements the transverse diameter of the section is broadened and the whole section assumes an approach to the triangular form, the base of which is directed forward; finally, the cord assumes the form of a half-moon on section, in the lowest segments, with its convexity directed backward.

When viewed exteriorly, the cord presents *five fissures* and *four columns*, which are less distinct than the convolutions of the cerebrum. On a section being made transversely across its substance, two general subdivisions can be discerned by the naked eye, the *white* and the *gray portions*.

The general exterior of the spinal cord is incompletely divided into two *symmetrical lateral halves*, by the so-called "antero-median fissure" and the "postero-median fissure," which do not cut the cord entirely in two, since a transverse commissure exists, called the "*commissure of the spinal cord*." Now, this point is worthy of your careful attention, since it indicates a clinical fact, viz., that lesions of one lateral half of the cord produce symptoms in a lateral half of the body.

Each lateral half of the cord has *three fissures of its own*: the "antero-lateral fissure," which corresponds to the points of escape of the anterior roots of the spinal nerves; the "postero-lateral fissure," which corresponds to the points of attachment of the posterior roots of the spinal nerves; and the "postero-intermediary fissure,"† which is situated between the postero-median fissure, that helps to divide the cord into its two lateral halves, and the postero-lateral fissure. The first two of these are mere traces upon the surface of the cord, while the last is most apparent in the cervical region.

As demarcated by the fissures named above, the spinal cord presents four subdivisions of its exterior surface, called, respectively, the "anterior," "lateral," "postero-external,"

* These enlargements correspond to the points of origin of the main nerves of the upper and lower extremities. They indicate, therefore, an excess of the ganglionic elements over those found in the dorsal region.

† The postero-intermediary fissure extends from the lower border of the medulla to the lower end of the cervical enlargement of the spinal cord. It is not associated with the transit of nerve roots, in which respect it differs from the antero-lateral and postero-lateral fissures.

and "postero-median" columns.* These are, however, of less importance, from a clinical standpoint, than the columns of fibers named, either after certain special investigators in this

FIG. 5. TRANSVERSE SECTION OF THE SPINAL CORD OF A CHILD, SIX MONTHS OLD, AT THE MIDDLE OF THE LUMBAR ENLARGEMENT, TREATED WITH POTASSIUM CHROMATE OF COBALT AND NITRATE OF UREA. (ENLARGED 20-DIAMETERS.) By means of these reagents, the direction of the fibers in the gray substance is rendered unusually distinct. (Griesch.)

a, anterior columns; b, posterior columns; c, lateral columns; d, anterior roots; e, posterior roots; f, anterior white commissure, in communication with the base of the anterior cornua and the anterior columns; g, central canal with its epithelium; h, surrounding connective substance of the central canal; i, transverse fasciculi of the gray commissure in front of the central canal; k, transverse fasciculi of the gray commissure behind the central canal; l, transverse section of the two central veins; m, anterior cornua; n, great lateral cellular layer of the anterior cornua; o, lower anterior cellular layer; p, subeolateral cellular layer; q, posterior cornua; r, ascending fasciculi in the posterior cornua; s, substantia gelatinosa.

line of science, or from their physiological functions. Subsequent cuts showing the transverse section of the spinal cord illustrate them.

When we come to discuss the clinical points pertaining to spinal localization, in case of disease, you will realize that the further subdivisions of the spinal cord, which I shall impress upon your memories, are not based alone upon the results of enthusiastic microscopy, but are the grand evidences of progress in this direction which the earlier anatomists had not dreamed of, and the foundation of all accurate and positive diagnosis of certain varieties of spinal lesions.

The spinal cord gives off *thirty-one pairs of nerves*, called "spinal nerves," in contradistinction to those of cranial origin. Each spinal nerve arises by two roots, which spring, respectively, from two of the fissures of the lateral halves of the cord, as has been mentioned. These two roots join each other to form the nerve before it escapes from the spinal canal to be distributed to the regions which it is destined to supply. Each pair of nerves and the disc of the cord to which they are attached constitute what is known as a "*spinal segment*."

* Some anatomists include the lateral with the anterior column, under the name of the "antero-lateral column," thus taking in about two thirds of the entire lateral half of the cord.

THE MEMBRANES OF THE SPINAL CORD.

As was the case with the encephalon, the spinal cord is invested from within outward by a *membrane of nutrition*, the pia mater; a *membrane of lubrication*, the arachnoid; and, finally, a *membrane of protection*, the dura mater. These three coverings differ slightly in some respects from those covering the brain, but the differences have little if anything to do with the clinical aspects of the spinal cord.

The DURA MATER of the cord is a cylindrical sac of fibrous tissue of larger dimensions than the cord. It is attached above closely to the foramen magnum of the occipital bone, and ends below by becoming blended with the periosteum of the coccyx. Its outer surface is invested by a layer of fat which separates it from the bones. As the spinal nerves perforate it, the dura and neurilemma become blended. The vertebral, intercostal, and lumbar arteries furnish it with blood. Large plexuses of veins are found on the anterior and posterior portions of the dura. These connect with the external vertebral plexuses.

The PIA MATER envelops the cord, like a tight-fitting glove, from top to bottom. It sends processes into the substance of the cord, which subdivide and form a framework for the nervous elements that compose it. It is also joined to the dura by from twenty to twenty-three processes upon each side, called the "*ligamenta denticulata*." These serve to retain the cord in its proper relations to the vertebral canal. The pia mater is rich in blood-vessels and nerves, and owes its toughness to a net-work of wavy connective-tissue fibers. Its nerves come from the posterior roots of the spinal nerves. In old subjects, the pia is often markedly pigmented in the cervical region.

The ARACHNOID, like all serous membranes, consists of a closed sac with a cavity between its two layers. The inner

FIG. 6.—This diagram has been introduced to show the arrangement of the different membranes and spaces as they are believed to exist in the spinal column. (After Hilton.)

1, 1, dura mater passing down to end on the sheath of the nerves; 2, 2, layers of arachnoid forming, 3, cavity of arachnoid; 4, 4, pia mater ending on nerve-sheath; 5, 5, ligamentum denticulatum; 6, gray matter of spinal cord; 7, delicate areolar tissue found in the sub-arachnoid space between the arachnoid and pia mater; 8, anterior and smaller, 9, posterior and larger, roots of spinal nerve; 10, 10, similar tissue to 7.

tissue, known as the "*sub-arachnoid tissue*," which contains a fluid called the cerebro-spinal fluid.

THE CEREBRO-SPINAL FLUID.

As mentioned in connection with the ventricular cavities of the brain, the spinal cord is immersed, as it were, in a fluid, the "*cerebro-spinal fluid*," which has free entrance to and egress from the ventricles of the encephalon, since its chief function is to regulate and equalize the pressure* upon the nerve centers, when the blood supply suffers variations, as it does during respiration, in sleep, and in certain diseased conditions. This accounts for the fact that pressure made upon a "*spina bifida*"—a tumor containing this fluid protruding through an opening due to a congenital absence of the spinous processes of the vertebrae—often creates brain symptoms, if sufficient to create excessive intra-ventricular pressure.

The greater part of this fluid is contained in what is known as the *sub-arachnoid space*, which is situated outside of the cavity of the arachnoid, between its inner layer and the pia mater of the cord. Its quantity was estimated by Magendie as about two fluidounces in the human subject; but a somewhat larger amount can be obtained by making an opening in the lumbar region and a counter-opening in the region of the head, so as to allow of the influence of atmospheric pressure in forcing its escape outward.

This fluid may be drawn out of the spinal canal of a living animal, either by means of a simple trocar or a trocar attached to a suction-tube. In the former method no apparent influence of a detrimental character seems to follow a moderate escape; but, when a suction force is used to still further draw off the fluid, the animal becomes enfeebled and subsequently affected with symptoms of motor paralysis. The cerebro-spinal fluid is rapidly reproduced after its withdrawal, and is probably secreted by the pia mater. The fact that an increase of the intra-cerebral pressure will result in coma, if sufficiently intensified, is shown, in a clinical way, upon the human subject, by compression of a spina bifida; and the same result was proved by Magendie, who injected water into the sub-arachnoid space of animals, and thus artificially induced a state of profound coma. The point of communication between the sub-arachnoid space of the spinal canal and the ventricular cavities of the brain is situated in the *fourth ventricle*; † hence, the fluid has to pass upward, through the aqueduct of Sylvius, to reach the third ventricle, and through the foramina of Monro, to enter the two lateral ventricles of the cerebrum. Hilton ‡ maintains that the basilar process of the occipital bone, which is in close relation to that part of the encephalon which is most essential to life, is not in actual contact with the adjacent brain, but has a layer of the cerebro-spinal fluid interposed as a water-bed to protect the parts from injury from any form of concussion, and a similar condition probably exists in other parts. The cerebro-spinal fluid is never in a

* Hilton considers this fluid as analogous, in respect to its function, to the elastic capsule of the various solid viscera. "*Rest and Pain*," London, 1876.

† The foramen of Magendie.

‡ *Op. cit.*

layer becomes blended with the pia mater as that membrane is prolonged upon the spinal nerve-roots (Fig. 6). Between the pia mater and the arachnoid there exists a loose areolar

state of repose. The influence of respiration affects it, by causing a decrease in the arterial pressure in the brain during inspiration and an increase during expiration. As a result of the variations in the volume of blood within the cavity of the skull, the cerebro-spinal fluid rises and falls in quantities sufficient to maintain an equal pressure upon the brain substance. It seems to be proved that the cerebro-spinal fluid is constantly secreted by the pia mater, and as constantly carried off by the lymphatic channels.

Hyrtl has suggested that the displacement of the cerebro-spinal fluid is facilitated to a marked degree by the emptying and filling of the veins of the spinal canal. He believes that the spinal veins are over-filled and distended during inspiration by the descent of the diaphragm, because pressure is then exerted upon the abdominal viscera by that muscle, and it tends to impede the flow of blood into the lumbar veins. The opposite effect, however, is produced at this time upon the cerebral sinuses, as they are emptied by the tendency to a vacuum created within the chest when the diaphragm becomes lowered. The return of the abdominal viscera, which follow the diaphragm when it relaxes (e. g., during expiration), assists in emptying the spinal veins; but at the same time it creates engorgement of the veins of the head and neck by interfering with the entrance of blood into the thorax. Thus it appears that the cerebro-spinal fluid is forced out of the ventricles of the brain during expiration by the excess of blood in the veins of that organ, and that the spinal veins are then empty, in order, as it were, to make room for the excess of the spinal fluid which is displaced by the cerebral engorgement. During inspiration, the direction of the displacement is reversed.

(To be continued.)

A PAROVARIAN CYST AND A FIBRO-CYST OF THE UTERUS IN THE SAME PATIENT.*

By WILLIAM M. POLK, M.D.,

PROFESSOR OF OBSTETRICS AND THE DISEASES OF WOMEN AND CHILDREN IN
THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW
YORK; GYNÆCOLOGIST TO BELLEVUE HOSPITAL.

THE patient whose case is here reported, a woman thirty-three years old, was admitted to ward 23, Bellevue Hospital, August 14, 1882. She had been married at the age of twenty-three. Her menstruation prior to that event had been regular; afterward it was irregular for the most part, and of late the flow had been accompanied by clots.

She became pregnant one year after her marriage, but miscarried when four months along. Several years passed without another pregnancy, and then she had two in rapid succession, each ending like the first. After the first, eight years ago, she had a severe illness, and this she thought was pelvic inflammation. It was at the time of this miscarriage that she was told by her physician that she had a tumor in the pelvis, and he expressed the opinion that it would prevent her carrying a child to term so long as it remained.

* Being remarks, with additions, made before the New York Obstetrical Society, June 5, 1883.

Seven years ago she first noticed an abdominal swelling, which has been present ever since. At first it was trivial, the enlargement seeming to be central; subsequently it became more prominent, occupying then not only the hypogastric, but the left iliac region as well. During the second and third pregnancies there was, of course, decided but temporary increase of the abdominal enlargement already existing, but, besides this natural variation, others were noticed. On three different occasions, while unimpregnated, there was a sudden diminution in the size of the tumor, and accompanying such diminutions there was a series of fluid discharges from the rectum, lasting usually a day or two. She always noticed that a large portion of the fluid discharged was not unlike white of egg in appearance and consistence.

For eight years there has been a slowly increasing impairment of her general health. When admitted to the ward, her appearance was that of a woman of forty-five. In feeble health, anemic, and poorly nourished, she was too weak to sit up. A slight cough, together with an afternoon rise of temperature, suggested phthisis, but a physical examination of the lungs failed to disclose any confirmation of our suspicions. Repeated examinations of the urine showed a constant trace of albumin, but at no time were there other evidences of renal disease found. A careful inquiry into her early history failed to reveal any trace of syphilis, but evidences of hereditary predisposition to phthisis were abundant.

Physical examination showed the abdomen about as large as at the seventh month of pregnancy. The uterus was of normal size, but displaced to the right. The vagina was small, and pushed well to the right by a fluctuating tumor that seemed to fill the entire upper half of the pelvic cavity and to extend into the abdominal cavity as far as the umbilicus. The rectum also was pushed to the right, the lower portion of the tumor resting between it and the upper third of the vagina.

A week after her admission five ounces of fluid were taken from the tumor. It was serous fluid, slightly cloudy, and presenting under the microscope the elements belonging to a simple ovarian cyst. No untoward result followed the tapping. The patient's condition was so unpromising that it was determined to postpone an operation, in order that her general health might be improved. Through the painstaking attentions, first of Dr. Pryor and then of Dr. Fruitnight, the house physicians, her health was so far improved by January, 1883, that she was deemed fit for operation. This was performed January 4th.

After the usual incision, a tumor, as large as a uterus five months pregnant, was found connected with the left broad ligament. It contained bloody serum. It was attached along most of the superior border of the broad ligament, so that its removal was difficult; finally it was accomplished by enucleation, a number of small ligatures being needed to control the bleeding from the stump. A second tumor was then found. This filled the pelvis entirely, pushing the uterus well up toward the outlet, and it seemed to involve the uterus in the neighborhood of the Fallopian tube. Fortunately, it had formed no attachments to its surroundings,

except the rectum. To the anterior wall of this organ it was closely adherent. Having been lifted from the pelvis, it was emptied and cut away close to its uterine and rectal attachments, these being very near each other. This remnant was then removed by enucleation, as had been done with the first tumor. The attachment to the uterus was so intimate that the manœuvre was accomplished with some difficulty; a portion of the uterus was included in the ligature. The attachment to the rectum was easily severed, the apposed peritoneal surfaces readily coming apart, leaving a round hole with cicatricial edges, a quarter of an inch in diameter, in the sac. Where this lay upon the rectum there was a circular depressed cicatrix of the same extent in the wall of the intestine. This was evidently the site of an opening from the sac into the gut, and it served to explain the several discharges from the rectum, and the accompanying diminutions in the size of the tumor, as noted in the history of the case.

After the pelvic peritonæum had been carefully cleansed, the abdominal wall was closed. The operation had consumed two hours, but the condition of the patient was excellent. She made a good recovery, and left the hospital at the end of three months.

The following is Dr. W. H. Welch's report on the nature of the tumor:

The specimen consists of one complete cyst and two portions of a second cyst.

Cyst First Removed.—The cyst is unilocular, and measures 18 cm. in diameter. Its outer surface is smooth and glistening. Its walls are thin and divisible into three layers: 1. An outer layer, serous. 2. A middle, fibrous. 3. An inner, mucous. The inner surface of the cyst is for the most part smooth. At one place, however, there are a number of small papillomatous growths. Adherent to the outer wall of the cyst is a small part of the Fallopian tube. The interior of the cyst is lined by cylindrical, ciliated epithelium. The wall of the cyst is composed mostly of fibrillated connective tissue. The characters of this cyst are those of a cyst of the broad ligament.

Cyst Last Removed.—Of the two pieces of the second cyst, one has a smooth external surface, like serous membrane; the other has a rough exterior, and is evidently devoid of peritoneal covering. The walls of this second cyst are much thicker than those of the first, measuring in places 2 cm. in thickness; in other places the wall is thin. This wall is not distinctly divisible into layers, but looks like dense, smooth muscular tissue. The inner surface of this cyst is partly smooth, partly irregular and rough; in a few places are papillomatous outgrowths. The microscopic examination of the wall of this cyst shows fibrous tissue, mixed with some smooth muscular fibers, and containing many blood-vessels. There are, especially near the inner surface, a number of soft, reddish nodules, some as large as a walnut. In these places are clumps of epithelial-like cells arranged in spaces. These places appear to be cancerous in their nature. No epithelium can be demonstrated on the inner surface of the cyst. This second cyst appears to be fibro-cystic, and to contain a few cancerous nodules.

"ROCK AND RYE" CANDY.—It is reported that an effort will be made to prohibit the manufacture and sale of "rock and rye" candy in Brooklyn. The superintendent of the Society for the Prevention of Cruelty to Children has represented to the Health Commissioner that its effects on children who use large quantities of the candy are pernicious.

A REMARKABLE CASE OF THE EXCESSIVE USE OF MORPHINE.

By LIVINGSTON S. HINKLEY, M.D.,

AVON SPRINGS, N. Y.

Mrs. P., a stranger, called at my office one day and, after a few preliminary remarks, announced that she was a consumer of morphine. As her own syringe had been sent away for repairs, she desired the loan of mine to take her daily dose, to which, after much persuasion, I consented, and was somewhat astonished when she produced a package containing twenty-five grains of the sulphate, and asked me to dissolve it in as little water as possible.

I hesitated, and inquired carefully into her history, which, after an hour's questioning, appeared so plausible that I dissolved the morphine, by the aid of heat, in about thirteen drachms of water, which she proceeded to use while warm, plunging the needle deep into her thigh and complacently filling the syringe and screwing it to the fixed needle for each successive syringeful. While this was going on I watched results. The patient was of good physique, twenty-six years old, weighed 145 pounds, and was a well-educated and intelligent woman. Her eyes were a little dull, and her complexion wore a pallor like the waxy hue of a patient with Bright's disease. After eight or ten syringefuls had been introduced, her cheeks became rosy, her eyes brilliant, her voice softened, and her speech more voluble, and she proceeded to give me the following interesting history:

Three years ago she was attended by her physician in her native city for a threatened abortion, during which time he began the use of morphine hypodermically, and from time to time increased the dose. This continued from the third to the eighth month, when premature labor took place, resulting in the birth of a dead fœtus. After this, finding that she could not resist the desire for morphine, her physician gave her a syringe and instructed her in the use of it. She at first feared to use it, and bought $\frac{1}{4}$ -grain pills, of which she took at first six per diem. After a few days this did not satisfy her, and she resorted to the use of the syringe—buying Magendie's solution by the ounce and gradually increasing her daily allowance.

During her second pregnancy the aforesaid medical adviser endeavored to reduce the dose, and succeeded in bringing it down to a ration of $\frac{1}{4}$ grain per diem. She lived upon this up to five months after her confinement. Then she used tincture of *Avena sativa*, in twenty-drop doses, as a partial substitute, for a whole week, without, strange to say, any beneficial effect. After her physician had finished with her case she again administered morphine to herself, and she remarked: "I do not know how I returned to large doses so quickly." She used, however, a drachm of the crystals each week for three months. At this period her husband, died, and grief caused her to become reckless. She declares that she took a drachm at night and twenty-five grains in the morning, and continued this quantity daily for nine days. Then, becoming fearful of the results, she reduced it to twenty-five grains in one dose once in twenty-four hours, and says she has continued to use it in

this amount up to the present time, but adds that sometimes, when she feels particularly "blue," she takes an additional twenty-five grains during the twenty-four hours.

Thus she lives from day to day, and carries on her occupation, that of a book agent, traveling from town to town, buying morphine in bulk, as she requires it, without the aid of a prescription.

She states that her hair is falling out rapidly, that she suffers severely from constipation, that her appetite is consequently much impaired, that she notices an increased excretion of urine, that her sleep is fitful, that sudden muscular spasms in some portion of her body occur frequently during the day, that her nerves are "unstrung," that she is easily frightened, easily irritated, and finds that she can not control her emotions as formerly. She says she has no uterine trouble, but that menstruation has not occurred in twelve months.

This patient came to my office on three successive evenings, and took twenty-five grains of morphine, as above stated, at each sitting. I have every reason to believe that the history she gives is truthful, and I believe that this records the largest quantity of morphine—viz., eighty-five grains—taken by any living being within twenty-four hours.

She manifested a strong desire to be relieved from this terrible servitude, but has no means to accomplish it. She remarked that she was willing to be incarcerated and take the chances of death or cure. I have her address, should an opportunity for her relief arise.

AVON SPRINGS SANITARIUM.

Clinical Reports.

ROOSEVELT HOSPITAL.

CLINICAL REMARKS BY HENRY B. SANDS, M.D.

Tuesday, February 19, 1884.

Two Cases of Varicocele.—Operation for Necrosis of the Testis.

CASE I.—This man, gentlemen, has a varicocele of moderate size on the left side, and comes here to be treated by operation. He is a robust Swede, twenty-two years old, who, with the exception of this infirmity, enjoys excellent health. Three years ago he noticed that the left side of the scrotum was larger than the right; he noticed also that the size of the swelling diminished when he assumed the recumbent posture, and became larger during hot weather. He has had uneasy sensations in the scrotum and thigh, and also pain in the back. He has worn a suspensory bandage without much benefit.

Here, then, is a case of varicocele in which the discomfort is out of proportion to the lesion. Many persons who have a varicocele of this size experience either no inconvenience, or so little that they are quite contented with the relief afforded by wearing a suspensory bandage. But this man seems to be greatly annoyed by his infirmity, and desires to be radically cured, if possible. I should not comply with his request to perform an operation if I was not satisfied that the one I am about to undertake was free from any risk. Or perhaps I ought to say that the risk is so trifling that it hardly needs to be considered. The severer forms of operation for the cure of varico-

cele—such as are intended to destroy the veins by caustic potash or by the actual cautery, or such as consist in the excision of the veins, or their ligation, in an open wound—I have never been tempted to perform. The operation which I prefer aims to obstruct the distended veins by a ligature of catgut applied subcutaneously. It is made to surround the veins by first transfixing the scrotum with a needle and carrying the thread between the vas deferens and the veins; the needle, having been passed through the scrotum, carrying the thread with it, is then passed in the opposite direction, from behind forward, entering and emerging through the same cutaneous punctures, but, instead of passing between the vas deferens and the veins in returning from behind forward, it is made to pass on the opposite side of the veins, so that when the ligature is tightened the veins are firmly constricted. The ligature and the dressing being antiseptic, no suppuration follows. This operation I believe to be the safest which can be performed for varicocele. In my own practice, only one fatal accident has followed the application of the ligature, which, however, was not antiseptic. In that case I performed Wood's operation, which had before, in my hands, yielded many excellent results. In doing it, a wire is made to surround the veins subcutaneously, and gradually, through the action of a spring, to cut through them or to set up a sufficient amount of inflammation to cause their obliteration. After this operation a certain amount of suppuration occurred invariably, and in the case to which I referred it was attended with septicaemia, of which the patient died. The wire broke a few hours after the operation, and had to be reapplied. Perhaps the interference with the wound which was thus rendered necessary may have given rise to the trouble that ensued. At all events, this accident is the only serious one which in my experience has followed the operation. As you are aware, operations on veins are not now dreaded as they used to be before the advent of antiseptic surgery, because the danger that results from infection of the thrombi can be obviated. With proper antiseptic precautions we do not hesitate to tie arteries and veins alike.

Now, it is necessary, in doing this operation, to be sure not to include the vas deferens in the ligature, as otherwise its function may be destroyed. The operation itself is not very painful, but severe pain, which must be allayed by opium, usually follows it. I am not accustomed to administer ether before the operation, but this patient insists upon taking it. With some difficulty I have been able to separate the vas deferens from the veins in this case, and I am obliged to vary from the usual rule and to ligate the veins to the inner side of the duct. Having constricted the veins with the ligature in the manner described, an antiseptic dressing is applied consisting of iodoform gauze. The patient will have to remain in bed for a week, and morphine will be given hypodermically, to quiet pain.

I have followed up the cases of some patients upon whom I have done this operation, and have found that in some instances the cure has been permanent. Two physicians upon whom the operation was performed about ten years ago have expressed to me the greatest satisfaction with the result.

CASE II.—The second patient is a young man who for more than two years has been troubled with a varicocele on the left side, of larger size than the one in the other patient, but, as he lies down, the difference in size is not so apparent. He has worn a suspensory bandage without relief. The enlargement of the veins is specially marked in the neighborhood of the testicle. In performing the operation upon this man I find no difficulty in separating the vas deferens from the veins, such as I experienced in the case of the first patient.

No special after-treatment is necessary, and suppuration is not likely to occur, as a very moderate amount of inflammation

is set up. There is no reason to believe that blood ever passes through the tied veins again. Still, it is well known that in this operation, however carefully it may be performed, all the veins of the cord are not included, and these may become so enlarged as to reproduce the disease. The operation, therefore, although called radical, does not always effect a radical cure, but enough good is accomplished in the majority of cases to repay the patient for the slight risk which is incurred.

CASE III.—This man is twenty-two years of age, a German, a barber, who came into the hospital on the 15th instant. His hereditary history is good. Four years ago his left foot near the ankle became hot, painful, and swollen, and subsequently an opening took place and discharged copiously. The opening never closed, but two others formed in the neighborhood. He knows of no cause for his disease.

Evidently this man has disease of the tarsus, not, I think, of the ankle joint, because the movements of the joint seem to be unimpaired, and there is no swelling around the joint. I am unable to say positively what bones are diseased, but the openings are on the outer aspect of the foot, and the probe passed into one of them detects carious bone. In my experience the large majority of cases of carious disease of the tarsus occurring in adults require amputation. In children, however, a large amount of bone can be removed, leaving the foot useful as a means of support. In the adult I think the prognosis after operations of gouging in cases of caries is dubious, and I do not undertake the operation with a very sanguine expectation of success. But, as it seems probable that the ankle joint is healthy and the disease of the tarsus limited, and as the man is unwilling to submit to amputation, I shall endeavor to remove the carious bone with a gouge, hoping that thereby his condition may be improved. Whether the operation does good or not depends partly upon the result of it as regards removal of the carious bone, and partly upon the severity of the operative procedure. If you succeed in taking out all the carious bone, the parts will frequently heal, and a cure will be accomplished. But if the carious process goes on, or recurs, you may finally be compelled to resort to amputation, which, if events could have been foreseen, had better have been done at the beginning. Also, if the disease is very extensive, requiring the removal of a large amount of osseous tissue, and especially if two or three of the metatarsal bones have to be removed, it is a question whether amputation is not the better procedure. In this case I hope the disease will not prove to be very extensive.

I have now gouged out a considerable portion of bone, apparently from the os calcis, the astragalus, and the external malleolus. The disease does not seem to have extended forward to the cuboid nor upward to the ankle joint. I am under the impression that I have removed all the diseased structure, and, if I have, I shall be hopeful of a good result. The wound will be packed with iodoform gauze, a peat-bag will be strapped on rather tightly with a bandage, and the foot elevated for a while after removal of the tourniquet, to prevent troublesome hæmorrhage. Before applying the dressings, however, I shall touch the surface of the wound with a solution of chloride of zinc, forty grains to the ounce, which is a superior disinfectant to all others when applied to suppurating surfaces.

FASCINATION.—M. Brémont has made, on sailors, soldiers, and officers, from fourteen to twenty-six years of age, a large number of experiments showing that lethargy, catalepsy, and somnambulism can be produced in healthy non-hysterical people, and that these phenomena are preceded by a peculiar state of fascination. The period of fascination is characterized by a sudden increase in the frequency of the pulse. One third of the young men experimented upon manifested one or more of the above-mentioned symptoms.—*British Medical Journal*.

Book Notices.

The Pathology and Treatment of Venereal Diseases. By FREEMAN J. BUMSTEAD, M. D., LL. D., late Professor of Venereal Diseases at the College of Physicians and Surgeons, New York, etc., and ROBERT W. TAYLOR, A. M., M. D., Professor of Venereal and Skin Diseases in the University of Vermont, etc. Fifth edition, revised and rewritten, with many additions by Dr. Taylor. With one hundred and thirty-nine woodcuts and thirteen chromo-lithographic figures. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. 906.

FOR more than a score of years this work has been accepted as a standard by the profession, and pride has been felt in it as reflecting the utmost credit on American medicine. It was in keeping with the late Dr. Bumstead's sagacity to determine upon a division of the labor of revising the fourth edition, when he found himself failing in health, and in keeping with his acumen to select so able and painstaking an associate as Dr. Taylor. The result is that, although the senior author has passed from among us, the work is kept quite up to the standard it originally assumed. As our knowledge grows, successive editions still, which can not fail to be called for, will necessarily come more and more to be the work of Dr. Taylor. Indeed, there is no lack of evidence in the volume now before us that the book is fast becoming an exponent of syphilography as it appears to a man yet busily engaged in its study and contributing to its progress.

When we noticed the fourth edition of the book we spoke of Dr. Taylor's rare power of clinical observation, his talent for terse and graphic description, and the internal evidence in every paragraph of his writing that he wrote whereof he knew. We may say, in general terms, that these qualities stand out with undiminished prominence in his work upon this edition, so that it is scarcely necessary to allude to particular portions. We may add, however, since the author calls attention to it in the preface, that he devotes a generous amount of space to an expression of the high esteem in which he has been led to regard coca as an adjuvant in the treatment of syphilis. The colored illustrations, thirteen figures on two plates, have been added by Dr. Taylor, and it must be said of them that they are admirable in execution and well calculated to aid in the elucidation of the text.

The work as it now stands is beyond peradventure destined to maintain for many years to come its position as one of the foremost medical books in the English language, or, for that matter, in any language.

BOOKS AND PAMPHLETS RECEIVED.

A Text-Book of the Principles of Physics. By Alfred Daniell, M. A., Lecturer on Physics in the School of Medicine, Edinburgh. London: Macmillan & Co., 1884. Pp. xx-653. [Price, \$5.]

Illustrations of the Influence of the Mind upon the Body in Health and Disease, designed to elucidate the Action of the Imagination. By Daniel Hack Tuke, M. D., F. R. C. P., LL. D., etc. Second American from the second English edition. Philadelphia: Henry C. Lea's Son & Co., 1884. Pp. xviii-33 to 492, inclusive.

The Home Physician: a Summary of Practical Medicine and Surgery for the Use of Travelers and of Families at a Distance from Physicians. By Luther M. Gilbert, M. D., Physician to the Connecticut General Hospital at New Haven, etc. New York: G. P. Putnam's Sons, 1883. Pp. vii-131. [Price, \$1.]

THE

NEW YORK MEDICAL JOURNAL,

*A Weekly Review of Medicine.*Published by
D. APPLETON & Co.Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MARCH 29, 1884.

ITALIAN MEDICINE.

We lately had occasion to speak of a new Italian journal of orthopædics. Now two other new and important serial medical publications have reached us from Italy. One of them is a year-book of medical literature, the "*Rivista Annuale delle Scienze Mediche*," edited by Dr. Enrico Martinez, under the direction of Professor Arnaldo Cantani, and published in Milan, Bologna, Naples, and Turin. Two large annual volumes, of about eight hundred pages each, seem to be contemplated, the first including anatomy and physiology, general pathology and therapeutics, special therapeutics, military and legal medicine, and general medicine, and the second covering internal and external medicine. These volumes are called part i and part ii, and we have received the first fasciculus of each. The plan seems to be very much the same as that of the French "*Revue des sciences médicales*," but with an amplification of the usual bibliographical lists somewhat suggestive of our own "*Index Medicus*." So far as the work has been carried in the fasciculi before us, it gives abundant evidence of great care having been taken to make it comprehensive and accurate.

The other publication to which we allude is a monthly journal of general medicine, the "*Rivista Internazionale di Medicina e Chirurgia*," edited by Professor Antonio Raffaele, Dr. Vincenzo Napolitani, and Dr. Domenico Morisani, and published in Naples. We have received the first two numbers, dated January and February of the current year. These early numbers are largely analectic, but they contain several important original contributions, including a Summary of the Present Status of the Question of the Contagiousness of Tuberculosis, by Dr. Napolitani, a Case of Aneurysm of the Ascending Aorta Cured by Galvano-Puncture, by Dr. Francesco Brancaccio, and a Case of Enucleation of the Corpora Cavernosa and Removal of both Testicles for Cancer of the Penis, by Dr. Morisani. Dr. Napolitani's article is of the character of a *revista sintetica*, a style of writing in which the Italians show great power. We scarcely need add that such an article, corresponding to the *revue critique* of the French, is of the utmost value to the reader, or that it demands a high order of ability on the part of the writer.

The Italians might well be proud of their achievements in medicine, if only by way of retrospect, for the old Italian anatomists and surgeons may fairly be said to have laid the corner-stone of modern medicine. But the present activity of the Italian profession, conspicuously illustrated as it has been in very recent years by such occurrences as the establishment of Porro's operation, the revision of our ideas of the constitution of the blood occasioned by Bizzozzero's investigations of the

third corpuscle, and the researches into the physiology of the uterine mucous membrane that have been largely stimulated by the profound studies of the late Professor Ercolani, needs only to be mentioned to be recognized by all who can make the slightest pretension to having kept themselves informed as to the progress of medicine.

But it is not alone in matters of investigation and practical advances that the Italians show to advantage; their literature is equally progressive. Scarcely has an important book in either the English, French, or German language passed through the hands of a few reviewers before an Italian translation appears, and in their periodicals, as will have been gathered from our remarks on the two new publications we began by alluding to, there is to be found a thorough picture of what is going on in the world at large. In view of all these facts, it seems to us that it would be well for the profession in this country to pay more attention to Italian medical literature than has been done hitherto.

PROPOSED LEGISLATION AS TO MIDWIVES.

THE action taken at the meeting of the Medical Society of the County of New York last Monday evening relative to the request that the society should lend its support to certain proposed legislation for the incorporation of the New York College of Midwifery, and for the licensing of midwives, seems to have been the most judicious that could have been taken under the circumstances. Of the two reports made by the committee appointed to consider the subject—the majority report and the minority report—it mattered little which was adopted, for they seem to have differed only in the intensity of their wording. Either of them was decided enough in its denial of the society's authorization of the scheme. The vote, however, was not so decided; the meeting seems to have been almost evenly divided. It is chiefly on this account that we think it well that the approval of the society was not given to the bills, for it would have been a questionable step for such a radical measure to have been sent forth with the formal approbation of the society to back it, when nearly half the members present at the meeting (supposing the vote to have been reversed) were opposed to the action.

It may be questioned whether the measures proposed would not, under ordinary circumstances, have secured more favor at the hands of the society; whether the talk that has lately been created by the way in which the school of midwifery already in existence has been managed has not had the effect of making opponents of many who would otherwise have voted in favor of lending the countenance of the society to the bills in question. The institution was already laboring under the stigma of having, as was publicly alleged, resorted to improper methods of advertising itself, when, on Monday, the day of the meeting, many of the members of the society received a circular, signed by a medical officer of the school, charging a gentleman who had resigned from its staff with having failed to make a proper accounting for the funds that had come into his possession. That the undertaking should have led to such a scandal thu

early, and that the startling charge alluded to was made public just at this time, undoubtedly had its effect.

Still, even if we allow that the considerations in question had no effect in shaping the action of the meeting, the vote was so close that, as one of the speakers prophesies, it seems not at all unlikely that the society will look at the matter of licensing midwives differently before many years have gone by.

THE COLLEGES AND THE PROPOSED STATE BOARD.

WHEN the two bills aiming at the establishment of State supervision in the matter of admitting graduates to the privilege of practicing medicine in this State were under consideration at the recent meeting of the Medical Society of the State of New York, it seemed to be generally felt that careful consideration was necessary before any measure could be devised that would work to the advantage of the profession and without injustice to vested interests. Manifest as that feeling was, so far as could be judged by what was said on the occasion, there has thus far been little disposition shown to discuss the matter in a broad way. Enough has been published, however, to indicate that, as is only too common, side issues are likely to distract the attention that should be concentrated upon the main question, and that an animus of one sort or another is to show its ugly head in place of that unalloyed striving after the good of the profession and the people that alone ought to actuate us in so grave a business.

In particular, there seems to be an insurmountable propensity in some quarters to view the college faculties and the bulk of the profession as arrayed against each other in a quasi-hostile attitude. We do not understand that there is any justification for such a view. The colleges have everything to gain, and nothing to lose, by maintaining an *entente cordiale* with the profession in general; on the other hand, the latter can have no real interest in degrading or humiliating the institutions for which, with scarcely an exception, they feel a regard almost filial. Hot words may come forth in the excitement of debate, and be caught up by mischief-makers, but it is generally understood how little weight should be attached to them. We do not believe that the physicians of the State of New York will allow designing men to draw them from their simple attempt to throw off the yoke imposed upon them by the delegation of legislative powers to inferior and utterly unworthy colleges into a crusade against the colleges in general. Nor can we conceive that most of the medical colleges in the State are of the better class—should construe the movement for the establishment of a State examining board as in any way tending to hamper their usefulness or to detract from the honorable place they hold in the esteem of the profession.

PORRO'S OPERATION.

It seems to us that Dr. Clement Godson, of London, did an inestimable service to obstetrics when he presented the subject of Porro's operation before the obstetrical section of the British Medical Association at its recent meeting, not only because

he was at great pains to give the most ample data bearing upon the present status of the operation from a statistical point of view, but because his appreciation of the value of the measure was eminently fair and discriminative. Dr. Godson gives an elaborate table of the main facts in one hundred and thirty-seven cases of the true Porro operation, and adds a postscript containing a short account of a very recent additional case.

Although the total mortality amounted to a fraction over fifty-five per cent., Dr. Godson is abundantly justified, we think, in maintaining that the operation is one from which gratifying results may legitimately be looked for in properly managed cases, meaning thereby cases in which it is not weakly put off as a *dernier ressort*, but done while yet the patient's general condition is such as to warrant the hope of a successful issue from any severe operative measure. It seems that in a large proportion of the cases the operation has been allowed scarcely a better opportunity than used to be accorded the Cæsarean section. Joined to the vigorous protest which on more than one occasion our countryman, Dr. Robert P. Harris, has raised against the policy of deferring laparotomy until the powers of life have been so wasted as to do away with almost the last chance of success, Dr. Godson's effective article will, it is to be hoped, tend decidedly to lead to a better course of practice.

MINOR PARAGRAPHS.

THE MEDICAL SOCIETY OF THE COUNTY OF KINGS.

SEVERAL weeks ago we announced the suspension of the monthly journal known as the "Proceedings of the Medical Society of the County of Kings," and we then expressed our regret that the journal in question was to be discontinued, together with our hope that, in some form, the proceedings of the society would still be published regularly. We are glad to be able to announce now that the proceedings will be published in this journal, and in this issue we print the first instalment. The society has done a good deal of excellent work in the past, and we believe that our readers will hereafter find the reports of its proceedings of interest.

THE "ARCHIVES DE TOCOLOGIE."

THIS monthly journal of obstetrics and diseases of women and children, founded more than ten years ago by the late Professor Depaul, may certainly now be said to have become firmly established in the favor of the profession. It has lately come under the more immediate editorial care of Professor Charpentier, and we discern a substantial improvement in its contents and in its general make-up. This improvement consists more especially in the addition of abstracts of current literature, largely in place of the diffuse clinical reports that formerly took up a great share of its space. When two such good journals as this one and the "Annales de gynécologie" are sustained by our brethren in France, it must be acknowledged that the field they cover is by no means neglected.

NEWS ITEMS, ETC.

POISONOUS HONEY.—The "Gazzetta degli Ospitali" quotes a correspondent of the "Gardner's Chronicle" to the effect that the honey produced by bees kept where aconite grows in abundance is poisonous.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending March 25, 1884:

DISEASES.	Week ending Mar. 18.		Week ending Mar. 25.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	9	2	3	2
Typhoid Fever.....	10	4	6	0
Scarlet Fever.....	112	19	83	15
Cerebro-spinal meningitis.....	4	4	9	8
Measles.....	62	9	72	9
Diphtheria.....	52	15	21	15

YELLOW FEVER.—Information is said to have reached San Francisco that yellow fever had broken out on board the United States steamer Iroquois, on the way to Alaska.

THE HEALTH OFFICER OF THE PORT OF NEW YORK.—The State Assembly has passed a resolution requesting Congress to enact a law depriving the Health Officer of his fees, with a view to establishing a salary for that officer instead. A bill now in the hands of the Judiciary Committee of the Assembly fixes the annual salary at \$10,000. It was under the impression that such a bill was unconstitutional that the resolution referred to was passed.

THE CATTLE DISEASE IN KANSAS, which at the time of our last issue was supposed to be the foot-and-mouth disease, seems now to be a gangrenous affection of the feet, due to admixture of spurred rye with the feed. The State Assembly has passed a bill establishing the office of State Veterinary Surgeon.

THE SANITARY CONVENTION AT MEMPHIS, held on Friday of last week, was attended by delegates from Illinois, Minnesota, Michigan, Missouri, Tennessee, Arkansas, Louisiana, and Mississippi.

A NEW ENGLAND SOCIETY OF MILK-PRODUCERS has voted that the State Board of Health, Lunacy, and Charity ought to regulate the sale of milk in a way calculated to insure its purity.

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.—On Friday evening of last week the faculty of the school gave a reception at the new building, in East Twentieth Street. The impression was general among those who were in attendance that the building was admirably suited to the purposes of the institution.

A CHARGE OF PRACTICING MEDICINE ILLEGALLY has been brought against the reputed proprietor of a Broadway "museum of anatomy" by the Medical Society of the County of New York, and the accused individual has been paroled pending an examination.

"SLUDGE ACID."—The New Jersey Senate has passed a bill prohibiting the pollution of rivers with this product, heavy penalties being attached to the violation of the prohibition.

"ROUGH ON RATS" is reported to have been the cause of an infant's death in North Carolina last week, having been administered with criminal intent by the child's nurse. It will be remembered that in our last issue we chronicled the poisoning of a New Jersey family with this preparation.

THE MEDICAL SERVICE ON PASSENGER SHIPS.—A bill has been introduced into the Lower House of Congress providing that any vessel bringing passengers to the United States shall be furnished with two hospital apartments on board, one for men and the other for women, each of an area of eighteen square feet for every fifty persons on board. The bill provides also that vessels carrying other than cabin passengers shall carry a licensed surgeon, if the ship's company exceeds fifty persons,

and an additional medical officer in case the number is more than six hundred, together with the necessary medical and surgical supplies. In view of the distinct statements lately made by Dr. Irwin, it is to be hoped that some such action will speedily be taken.

THE STATE MEDICAL SOCIETY OF ARKANSAS will hold its ninth annual session at Little Rock, on Wednesday, April 30, Thursday, May 1, and Friday, May 2, 1884, commencing at 10 a. m. on Wednesday.

DRUGGISTS AND THE NOSTRUM TRADE.—It is reported that the recent action of Brooklyn druggists who agreed upon a specified price for patent medicines has been rescinded, on the ground that the battle ought to be fought by the manufacturers. As the matter now stands, the prices of these necessary (?) evils are at the option of the seller.

THE NEW YORK ACADEMY OF MEDICINE.—At the next regular meeting, to be held Thursday evening of next week, Dr. Henry J. Garrigues will read a paper on the Removal of the Placenta.

THE STATE BOARD OF HEALTH, it is reported, has chosen Dr. Alfred L. Carroll, of Staten Island, its secretary, in place of the late Dr. Elisha Harris. The board has been fortunate in securing the services of so capable a sanitarian as Dr. Carroll.

IMPURE ICE.—The Legislature of Connecticut has passed a bill making the sale of ice taken from polluted waters punishable by a fine of fifty dollars.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 16, 1883, to March 22, 1884:*

BACHE, DALLAS, Major and Surgeon. Leave of absence still further extended seven days. Par. 1, S. O. 50, Headquarters Department of the East, March 14, 1884.

MATTHEWS, WASHINGTON, Captain and Assistant Surgeon. To be relieved from duty in the Department of Missouri, and to report in person to the Surgeon-General of the Army for duty in his office. Par. 12, S. O. 62, A. G. O., March 15, 1884.

BLACK, CHARLES S., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Concho, Texas. Par. 6, S. O. 30, Headquarters Department of Texas, March 10, 1884.

GIBSON, R. J., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Hays, Kansas, and ordered to Fort Wingate, N. M., for duty. Par. 3, S. O. 58, Headquarters Department of Missouri, March 18, 1884.

CROSBY, WILLIAM D., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Huachuca, A. T., and ordered to Fort McDowell, A. T., for duty. Par. 1, S. O. 20, Headquarters Department of Arizona, March 15, 1884.

EDIE, GUY L., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort McIntosh, Texas.

ROBERTSON, REUBEN L., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Ringgold, Texas. Par. 3 and 4, S. O. 33, Headquarters Department of Texas, March 17, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending March 22, 1884:*

STREETS, T. H., Passed Assistant Surgeon. Relieved from Museum of Hygiene, Washington, for duty in the Coast Survey Service.

HALL, C. H. H., Passed Assistant Surgeon. Ordered from the Naval Academy to the Museum of Hygiene.

STEWART, HENRY, Surgeon. Ordered before the Retiring Board.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Tuesday, April 1st:* New York Obstetrical Society (private); New York Neu-

rological Society; Buffalo Medical Association (annual); Elmira, N. Y., Academy of Medicine; Croton Medical and Surgical Union (Katonah, N. Y.); Ogdensburg, N. Y., Medical Association; Medical Societies of the Counties of Broome and Niagara, N. Y., and Essex (annual), Hudson, and Union, N. J. (annual).

Wednesday, April 2d: New York Medico-Legal Society; Medical Society of the County of Richmond.

Thursday, April 3d: New York Academy of Medicine; Society of Physicians of the Village of Canandaigua, N. Y.

Friday, April 4th: Practitioners' Society (private).

OBITUARY NOTES.

DR. CHADBOURNE W. WHITMORE, OF GARDINER, ME., died recently in Washington, where he had gone on account of failing health. He was sixty-three years of age and a physician of considerable prominence. He was a member of the Maine Medical Association. His death is supposed to have been due to heart disease.

DR. WELCOME W. SPEAGUE died on Wednesday last at his residence, No. 149 East Nineteenth Street. He was a member of the Medical Society of the County of New York, and a graduate from Bellevue Hospital Medical College in 1875.

Letters to the Editor.

THE USE OF CELLOIDIN AS AN IMBEDDING MASS.

18 EAST FORTY-FIRST STREET, March 19, 1884.

To the Editor of the *New York Medical Journal*:

SIR: In your journal of the 15th inst. there appeared a query in regard to the use of *celluloid* as an imbedding mass. The probabilities are that your inquirer had reference to *celloidin*, which has been quite extensively used for that purpose.

Celloidin was first introduced into histological technique by Schiefferdecker ("Ueber die Verwendung des Celloidins in der anatomischen Technik," *Arch. f. Anat. u. Phys.*, anat. Abth., 1882, pp. 199-203), and has met with general favor. It is a pure pyroxylin, free from all foreign organic constituents, and makes a clear solution free from sediment. It is soluble in equal volumes of alcohol and ether, and the degree of concentration may be varied to suit any particular case.

The following is the manner of preparing and using the material, as practiced in the laboratory of the Alumni Association of the College of Physicians and Surgeons: A saturated solution of celloidin is made in a mixture of equal parts of ether and alcohol (97 per cent.); this requires about twenty-four hours, with occasional agitation. The specimen to be imbedded is soaked in a mixture of ether and alcohol for some time, then transferred to the imbedding fluid and allowed to remain overnight.

One of two ways of imbedding may be adopted:

1. Cover the smooth surface of a cork with a thick layer of celloidin solution and allow it to dry; place the specimen, which has previously been soaked in the imbedding fluid, on this, and cover it, layer by layer, with a solution of celloidin, allowing each layer to partially dry before applying another. When the specimen is completely covered, immerse in alcohol of 80 per cent. for twenty-four hours, when it will be ready to cut.

2. The specimens are imbedded in paper boxes in the usual way, or a cork is wrapped with one or two layers of thick writing paper, allowing it to project an inch or an inch and a half

above the surface of the cork. By this procedure a round box, with the cork for a bottom, is obtained. Into this box pour a small quantity of the imbedding fluid, and allow it to dry. The specimen, having been previously soaked in the celloidin solution, is now placed in the box, adjusted as to position, and allowed to dry for five or ten minutes, so as to fix it; the box is now filled with the imbedding fluid. The boxes are exposed to the air until the imbedding mass has become semi-solid, and are then immersed in weak alcohol (alcohol 95 per cent., two parts, water one part) for twenty-four hours, when the specimen will be ready for cutting. If the specimen has been imbedded in a paper box and sections are to be cut with a sliding microtome, it is necessary to mount it on a cork. This is accomplished in the following manner: Cover the surface of a smooth cork with a thick layer of celloidin solution, allow it to dry, and again cover with the same. Trim off the superfluous imbedding mass from around the specimen, cut the lower surface even, wet it with a drop or two of ether, and adapt it to the layer of celloidin on the cork. Dry for a few moments and place in dilute alcohol for a few hours, when the specimen will be ready for cutting. If the plan of imbedding in the boxes with a cork for a bottom is adopted, the specimen is imbedded and mounted on the cork at the same time.

Sections may be stained with the different staining fluids and mounted in glycerin or other media. If mounted in Canada balsam, and the specimen is to be retained in the imbedding mass, absolute alcohol for dehydrating and oil of cloves for clearing are to be discarded, for they both dissolve the celloidin, and alcohol of 96 per cent. and oil of bergamot, oil of sanders, or oil of origanum, used.

Celloidin is manufactured by E. Schering, of Berlin, and may be obtained of Bachrach & Brother, Baltimore, Md. It comes in the form of gelatin plates and shreds, put up in ounce packages. The shreds are to be preferred on account of being more easily dissolved.

Very truly yours,

G. C. FREEBORN, M. D.

NEW YORK HOSPITAL, PATHOLOGICAL DEPARTMENT.

NEW YORK, March 19, 1884.

To the Editor of the *New York Medical Journal*:

SIR: At the laboratory of the New York Hospital the following method is employed in imbedding objects in celloidin: The celloidin, which is a hard, semi-transparent, colorless material, is cut into small pieces and dissolved in a mixture of equal parts of absolute alcohol and ether until the solution is of a thick, creamy consistence. The solution should be kept in a wide-mouthed bottle, closed by a tight-fitting ground-glass stopper. The object to be imbedded is placed in absolute alcohol for two days to remove all the water, then for a day or two in ether, and is then ready for imbedding. The object is then placed in the celloidin, and left there until it is thoroughly soaked through by it. This lasts about four days. When fine sections of delicate tissues—as the lung, spleen, retina, or testicle—are desired, it is better to leave the object in for a week. After removing the object from the celloidin, place it in ordinary alcohol for a short time. The alcohol coagulates the celloidin, and gives the mass the consistence proper for cutting. Absolute alcohol must be avoided, as it dissolves out the celloidin. The object can now be placed on a suitable-sized cork, the surface of which is covered with a few drops of the celloidin solution or an ordinary (thick) solution of gum arabic, and the cork, with object attached, is placed in ordinary alcohol to harden. After hardening, the cork can be fastened in the clamps of a microtome or held in the hand, and the sections cut. The sections can be stained, and mounted in glycerin or in balsam. When mounted

in balsam, the sections must be cleared in oil of thyme or bergamot, but not in oil of cloves, as the latter dissolves the collodion, and renders the mounting of delicate sections almost impossible. I would add that the collodion may be obtained of George Inness, 45 University Place.

Very truly,

F. W. MURRAY.

PHYSICIANS' AID TO THE INDIGENT.

CHARITY ORGANIZATION SOCIETY OF THE CITY OF NEW YORK. }
CENTRAL OFFICE, 79 FOURTH AVENUE, March 25, 1884. }

To the Editor of the *New York Medical Journal*:

SIR: Will you please advise the medical profession, through your valuable journal, that we find many cases where notes of recommendation given to their free patients for specific objects or for a temporary emergency are used for general and indefinite begging purposes, and minister to vice and idleness and debauched lives? It is rare that such open indorsements are used as the writers intended, and at any rate the temptation to misuse them is very great. At the best, the relief procured through such letters is very uncertain, while there is hardly any condition more cruel to the self-respecting and worthy sufferer than to compel him or her to beg hap-hazard alms from strangers, by the aid of such a letter, which those not familiar with the handwriting will generally distrust. Physicians may refer to us such cases as they are interested in and can not help adequately themselves, and we will do our best to bring to bear upon them all charitable resources of the city.

Yours very truly,

CHARLES D. KELLOGG,
Organizing Secretary.

Proceedings of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Meeting of March 24, 1884.

ANDREW H. SMITH, M. D., Vice-President, in the chair.

BLINDNESS FROM THROMBOSIS OF THE RETINAL BLOOD-VESSELS IN FACIAL ERYSIPELAS.—Dr. H. KNAPP read a paper on this subject, in which he first reviewed the histories of a number of cases which had been reported, and then stated that he had had a rare opportunity of observing with the microscope a very marked case from the onset to the end—one which exhibited changes not yet described, so far as he knew. The patient was a man forty-one years of age, a merchant, who had lived in the tropics, but from time to time had been in New York. When the weather became inclement he suffered from erysipelas. Last March he suffered from an attack which began in the nasopharynx, and the swelling very soon extended irregularly to the face, involving the eyes and spreading over the scalp. On the sixth day an alarming symptom set in; the patient, who was able to open his swollen eyelids, said he was blind in the right eye. The next day Dr. Knapp was called in consultation, at which time the sight of the other eye had also been lost. Both eyes were intensely swollen and hard, the balls were immovable, and the conjunctivæ were chemotic. Incisions had been made almost two inches in depth, but without liberating pus. Dr. Knapp found a rigid right cornea, somewhat hazy from exposure, but sufficiently clear to allow of examination of the fundus. The left cornea was perfectly clear, and the lids could be sufficiently parted to admit of a good ophthalmoscopic examination. The media were perfectly clear. The appearances

he found in this eye were peculiar, but not altogether new to him, as he had now and then seen them after extirpation of a tumor from the optic nerve, and after some other operations. They consisted mostly of a deficiency or absence of the arteries, the condition which was to be found in such cases on the first or second days—the blood-vessels uniform in character, and unlike anything we were accustomed to see with the ophthalmoscope. Looking over the optic disc, we saw it indicated only by a convergence of the vessels, none of the details of the disc being visible. The blood-vessels were distinguished by their tortuosity and dilatation, and almost black color. The fundus was of a milky opacity. At the periphery the color was normal. Besides, there were numerous dark hæmorrhages. Pressure upon the eyeball produced no change in the picture. It was attributed to an interruption of the blood supply of the retina, compression of the artery and also of the retina; probably the vein was compressed first and then the artery, while the artery with its thicker and more resistant walls still led the blood into the eye, filled the veins, and produced hæmorrhages either in the way of rupture of the small vessels or by diapedesis. The prognosis was considered unfavorable so far as restoration of sight was concerned. The patient never had marked cerebral symptoms. Two days later the swelling of the orbit was diminished, the lids opened better, and the patient felt much better. There was a little ulcer of the right cornea which cleared up, and a view was had of both retinæ. Ophthalmoscopically, the veins had not changed their character, but the arteries were very thin, bright-red lines radiating in the ordinary way, and there was not the slightest doubt but that blood had been carried into the interior of the eye. There were quite a number of recent hæmorrhages. In neither eye was there perception of light, nor had there been since. Gradually the patient recovered his general health, the swelling of the orbits disappeared completely about the fifth week, the balls retreated into their sockets and moved again naturally, there was no increase of tension, the cornea regained its luster, the pupil became moderately dilated, and changes gradually took place within the eyes which interested Dr. Knapp exceedingly. The veins presented the appearance of a rosary, and gradually some of the blood-vessels became interrupted by completely white portions as thick as the vessels. In the course of weeks these white portions, having extended, coalesced, and finally, after about three months, all the blood-vessels except a very few were converted into shining white lines. Only a few contained blood. The patient had been seen several times since, and there was no marked change. He was totally blind. When sight was once lost in these cases it commonly remained lost.

Dr. Knapp briefly referred to the pathology of erysipelas, and stated that the arterial blood-vessels within the eye had transparent walls, and, when the blood supply was cut off, they could not be traced. By pressure during the course of the disease the blood might be cut off and all trace of the arteries disappear, and again reappear when the pressure was removed and the blood allowed to circulate; then there might be a new occurrence of hæmorrhage or of diapedesis. It was known that blood might stand in a vessel and not coagulate, provided the walls of the vessel were normal. In the cases in question the blood in the retinal vessels after a time became organized after the manner in which connective tissue would be thrown out into the meshes of a sponge when left in contact with the broken tissues. Afterward there would be cicatricial contraction. With regard to treatment, we should have to depend largely upon prophylactic measures against erysipelas. In orbital cellulitis of any form the indications were to do away with pressure as early as possible by incision, even if there were no pus. Such a course at least was perfectly rational, but experi-

ence had not yet fully determined its practical value in these cases.

Dr. E. G. LORING said the opportunity to observe these cases occurred very rarely. He had not seen one in the beginning, but had observed the condition in a more advanced stage. He alluded to a case reported at the American Ophthalmological Society in 1879, which had not been mentioned by Dr. Knapp. Dr. Loring was inclined to think that the condition described was due to a phlebitis propagated directly to the walls of the retinal vessels. So far as pressure was concerned, he had seen cases of orbital inflammation from other causes than erysipelas in which there was the greatest degree of pressure, and yet sight and the retinal circulation seemed not in the least impaired.

Dr. T. R. POOLEY thought the explanation of the ophthalmoscopic appearances given by Dr. Knapp quite ingenious and rational as applied to certain cases, but there were some instances in which there was blindness with atrophy of the optic nerve, while there was but slight diminution of the retinal artery, in which it would hardly hold. With regard to transudation from the retinal blood-vessels, or diapedesis, he thought it would not explain the hæmorrhage; he would rather suppose there was actual rupture of the vessels.

The subject was further discussed by Dr. WEBSTER, Dr. HOBROOK, Dr. SMITH, and the author, who said, with regard to the presence of phlebitis, that there was no indication of the same in the walls and around the veins. As to diapedesis, he had also thought there could be no hæmorrhage without rupture of the vessels, until the contrary had been proved recently.

THE COLLECTIVE INVESTIGATION OF INTESTINAL OBSTRUCTION.—Dr. DAVID WEBSTER, chairman of the committee, said that about fifty cases had been reported in response to the circulars sent out, all of which were very interesting, and would be worth listening to; the hour was advanced, however, and, as there was still other important business to bring before the society, he moved that when the society adjourn it adjourn to meet on the 7th of April, for the purpose of taking up this subject. Carried.

THE COLLEGE OF MIDWIFERY AND THE LICENSING OF MIDWIVES.—Dr. W. M. CHAMBERLAIN, as chairman of the committee appointed to consider this matter, handed in a majority report, stating that in the opinion of the committee it was not expedient that the society indorse or support the bills. The question of the conditions under which others than registered physicians should practice midwifery seemed to be an important and a difficult one, and, in the opinion of the committee, might properly be referred to a special committee, or to the comitia minima, for examination and report.

Dr. RALPH WALDO read a minority report, signed by himself, to the effect, first, with regard to the proposed New York Maternity and School of Midwifery, the committee did not recommend the society to indorse or commend the incorporation of such an institution, because it would not be conducive to the reputation of the medical profession and the good of the community. Second, in regard to the proposed act licensing midwives, the committee could not recommend that the society approve of any State legislation giving licenses to practice midwifery or any branch of medicine to persons who were not duly licensed physicians.

Both reports were accepted, and it was moved that the minority report be adopted. Some discussion followed, in which Dr. POLK, Dr. JACOBI, Dr. ALSDORF, Dr. WALDO, Dr. MUNDE, Dr. JOHNSON, Dr. BRILL, and others participated. This motion was withdrawn in favor of one offered by Dr. JACOBI, a member of the committee, that the consideration of both reports be indefinitely postponed. A rising vote was called for, and the motion was lost by one vote. It was then moved that the ma-

jority report be adopted. Lost. It was then moved that the minority report be adopted. Carried.

Dr. JACOBI said he thought that the society should not declare itself against the future consideration of so important a question as the training and licensing of midwives. He perhaps could not fully indorse the form of the bill as it had been drawn, proposing the establishment of the New York School of Midwifery, but that there should be some training school and legislation regulating the practice of midwifery he firmly believed, and it was his opinion that the society would view the matter in a different light within a year or two. He therefore moved a reconsideration of the vote just cast.

Dr. POLK thought it questionable whether the society ought to lend its influence in favor of special legislation in this matter. It was desired that an institution should be incorporated which should receive twenty-five dollars for every confinement case within its wards. This was a demand which every maternity institution in the city had an equal right to make, and the institutions now in existence were probably better suited to carry out the purposes in view than the one proposed was. It was putting midwifery on rather a low plane to trust it to midwives with six months' education in that direction. There was no department of medicine which required more careful education on the part of the practitioner than that of midwifery. The great advances which had been made in midwifery all over the world had been made since it had been taken out of the hands of ignorant women. He said *ignorant* women, and did not refer to those who were graduates of a regular medical college. It was argued on the other side that poor people, who were able to pay but a small sum, had a right to be attended by competent midwives. In reply, it could be said that there were plenty of competent physicians, men and women, in this city, who were willing and would be glad to attend all such cases, and, if necessary, for absolutely no pecuniary remuneration. There were at least fifty educated young men connected with any one of the three principal medical colleges who would freely attend such cases. If there were women or nurses who desired specially to attend women in confinement, they could obtain any amount of experience by making their request known and entering the maternity hospitals already in existence as nurses; there they could stay, not only six months, but sixteen months if they desired.

The motion to reconsider the vote was then put, and declared lost.

MEDICAL SOCIETY OF THE COUNTY OF KINGS.

Meeting of February 18, 1884.

GEORGE G. HOPKINS, M. D., President, in the chair.

A MEMORIAL OF THE LATE Dr. J. MARION SIMS.—The special committee appointed to prepare a memorial of the late Dr. Sims presented the following:

J. Marion Sims, A. B., M. D., LL.D., in many respects the greatest gynecologist of the century—an honorary member of this society—died very suddenly and unexpectedly at 3.15 A. M., Tuesday, November 13, 1883, at his residence, 267 Madison Avenue, New York city. He was born in Lancaster District, S. C., January 25, 1813, and received his earlier education in the common school, completing it by receiving the degree of A. B. from the College of South Carolina, at Columbia, in 1832. He then began the study of medicine in Charleston, but graduated from the Jefferson Medical College, Philadelphia, in 1835.

The next year he commenced general practice in Montgomery, Ala., but soon became interested more particularly in surgery.

On the plantations in the neighborhood many negro women

suffered from vesico-vaginal fistula, and, after a time, the greater part of these were sent to Dr. Sims, who established a small private hospital with sixteen beds.

It was while practicing with this class of patients that he conceived the idea of radically curing this affection. He met with very discouraging results for four years, which he attributed largely, if not principally, to the use of silk sutures, until he began, in 1849, to make use of silver wire. This proved, by his speedy successes, to be a marked step forward in the treatment. In fact, he strongly urged the silver suture in all the departments of surgery. Early in his practice with this class of cases he recognized the need of some means by which retraction of the perineum might be obtained, and he devised, in 1845, his world-renowned speculum.

His health broke down in 1850, and he was confined to his bed for a considerable part of his time. It was while thus confined that he prepared the first account of his operation for vesico-vaginal fistula, which he published in the January number of the "American Journal of the Medical Sciences" for 1852.

Seeking, then, for better health in the North, and a wider field of usefulness, he removed to New York city in 1853. Here the same spirit moved him as in Alabama, to alleviate the suffering of women. It was only a year after his arrival that he got up a public meeting and interested a few influential men in instituting a hospital for the treatment of diseases of women. The result, then, was the opening of such a temporary hospital at once. In 1857 a charter was obtained and an appropriation made for a permanent hospital.

As the selection of a plan for the building was largely left to him, he traveled through Europe in 1861 to study the construction and management of such institutions there. Soon after his return to this country our civil war broke out. This, of course, put a stop temporarily to building operations on the hospital. In 1862 Dr. Sims took his family to England, settling in the west-end of London. He remained abroad for the greater part of the following six years. During this prolonged stay he was not only made a member of most of the prominent medical societies of Europe, but he was decorated with honors by France, Belgium, Italy, Spain, and Portugal—Napoleon III making him a Knight of the Legion of Honor, and Belgium bestowing upon him the order of Leopold I. He practiced extensively abroad, especially in London, and in the beginning of 1866 his work on "Clinical Notes on Uterine Surgery, with Special Reference to the Sterile Condition," was published in that city, which contained such new and startling views that it created a considerable sensation.

In 1866 the first new pavilion of his hospital in New York city was ready to receive patients, and in 1868, when he returned from Europe, he took full charge of the hospital, then running on a more substantial basis. He was during this year elected an honorary member of this society.

He again visited Europe in 1870, and when in Paris, at the outbreak of the Franco-Prussian war, he was selected to accompany and direct the Anglo-American Ambulance Corps. This was the pioneer corps in the service, and gained considerable fame and rendered incalculable service under his directorship.

After returning to America he resumed his services in the Woman's Hospital, but in 1874 he resigned from the Board of Surgeons on account of some unwarrantable rules inflicted on the surgeons by the governing board. Since that time he had not taken any active part in the institution.

From this date on he moved about considerably between Paris, London, Rome, and New York.

At the Louisville meeting of the American Medical Association in 1875 he was elected its president, and on June 6, 1876,

he delivered his inaugural and centennial address at the meeting in Philadelphia.

On April 18, 1873, when in Paris, he performed for the first time the operation of cholecystotomy—a hitherto unknown name and method—for dropsy of the gall-bladder.

During the winter of 1880-'81 he was attacked by pneumonia, which nearly proved fatal. While in London, Dr. Ord, of St. Thomas's Hospital, treated him with great kindness and skill, and gradually he recovered. On October 6, 1881, he read his paper on "The Treatment of Gunshot Wounds of the Abdomen in Relation to Modern Peritoneal Surgery" before the New York Academy of Medicine. This paper he afterward published in the "British Medical Journal." Conspicuous among his other notable articles are those on "Ovariectomy," "Intra-uterine Fibroid Tumors," and "A History of the Discovery of Anesthesia."

Since his last return from England his health had been very fair, and hopes were entertained of his complete recovery. Even up to his last day no outward signs whatever were evident of the impending dissolution. He was preparing to leave for Europe on Saturday, November 17th. His death was due immediately to atheroma of the coronary arteries, with sudden obstruction of the circulation.

As a surgeon, Dr. Sims was skillful, brilliant, and original. Fertile in expedients, he was never thrown off his guard, was ready for every emergency, and never shrank from performing the most hazardous operation when the welfare of his patient demanded it. His perseverance in difficult cases when others would have been discouraged, and his fertility in applying remedies, sometimes bold and often novel and striking, were conspicuously shown.

As a man, he was affable and accessible to all, and the native simplicity of his manners and his gentle feelings excited profound respect and conciliated universal esteem. In the heat of debate his soft and gentle nature was sometimes provoked, under trying circumstances, to use harsh expressions, but he was always magnanimous. His bitterest sarcasm was followed by an ample apology when justice required it. He exhibited a generous sympathy for the afflicted and suffering which at once engaged their affections and confidence. His patients loved him as a personal friend. His death is deplored by the world, and his name will live in the remotest times.

[Signed]

JO. C. HUTCHISON,
J. N. FREEMAN,
PAUL H. KRETZSCHMAR,
E. H. SQUIBB,

Committee.

Dr. A. J. C. SKENE made the following remarks:

In this age men have attained a higher general intelligence and are more nearly equal than at any time in the history of the world.

This elevation of the masses tends to overshadow those who by their superior gifts do noble deeds and become truly great. Justice to the many often modifies the homage given to the few. Still there are men who advance beyond the front ranks and command special attention and higher honor. Such a man was J. Marion Sims.

He left the crowd of gentlemen who contentedly practiced the known and accepted in medicine, to seek new and better means to meet the requirements of suffering women, and he succeeded to the gratification of his own kind heart, the glory of his profession, and the honor of America.

He did original work, and he did it so well that others were able to follow him. When he entered the profession he observed the need of a new department in surgery, and he created it. He gave the key to the art of gynecology, and nearly all

that has been added to it since has been discovered through the means of observation which emanated from his brain.

Nature liberally endowed him for his life-work—the gift of appreciating the wants of the human race, the ingenuity to find means for their relief, the enthusiasm and courage to act upon his convictions, and the personal fascination which enabled him to control others and bring them to see and believe as he did. All this enabled him to do good deeds, and secure the appreciation of his fellow-men; hence to-day he is known and admired in all civilized nations, and his name is found on almost every page of modern medical literature pertaining to woman.

As a great man vanishes from our sight his merits are often magnified when viewed through our tears, and he appears greater and better than when viewed through our smiles of approbation or scowls of envy while he was yet near us. But Dr. Sims will surely remain in memory as he really was while he lived, a master workman who rendered valuable and rare services to his fellow-creatures.

He was not inclined to search for the obscure and profound in science, but he was able and energetic in his efforts to improve the healing art. His watchword must have been, What can I do to save and restore? He aimed to be useful in all he did. In this he was a representative American surgeon. The circumstances of his life and the intensity of his disposition frequently interrupted him in his work, so that while he accomplished much he was capable of far more. If he had remained continuously in practice here, his record, while it might not have been higher, would have been fuller and more complete. Had some admiring friend played the part for him that Boswell did for Johnson, and preserved the hints and suggestions which came thick and fast from his ever-active mind, another volume would have been added to our literature and another monument to his honor.

Along with his talents for which he was admired, he had many humane qualities which gained the love of men. Prominent among these was his keen appreciation of the merits of others. He was ever the first to sincerely compliment and encourage the deserving among his professional brethren, and was ever ready to sympathize with, pity, and forgive the weak and erring; so always he found his way to men's hearts as well as their heads.

Any word that I may say will neither add to nor take from the estimation in which men hold J. Marion Sims; but it is a duty, which one eagerly seeks to perform, to add one leaf to the mass of flowers that have been laid upon the grave of this great man.

Dr. WALTER B. CHASE said:

MR. PRESIDENT: Not often in the history of this organization have we been called to mourn the loss of a brother—either from its active or its honorary membership—whose life and work filled so important a place in medical history and honorable renown! It is not my purpose to pronounce his eulogy, but simply to call to mind some of those noble characteristics which made him what he was. Personally, my acquaintance with him was limited. I knew him as most of you knew him, and as he was known to the medical profession, a man we all delighted to honor, a brilliant surgeon, and an earnest searcher after truth; and yet I shall never forget the time I first met him. It was in the operating-room of the New York State Woman's Hospital—a noble monument to his untiring zeal and energy. There were a cordiality in his greeting and a sincerity in his words and manner which left an abiding impression upon me.

From a recent memorial it appears there was nothing especially remarkable in his early life. None foresaw the brilliant future before him. He was possessed of superior endowments,

pronounced in his personality, self-reliant, and a man of genius. This, with his sympathetic nature, and desire to relieve human suffering, carried him to his pre-eminently high position. The Southern blood which flowed through his veins gave him an impetuous nature, but with it were the lofty aim and the noble purpose. There are ever and always around and above us the new and mysterious, both in nature and in art. It was his province to penetrate something of these mysteries in the domain of surgery. No one at this present time can estimate the far-reaching and beneficent results of his teachings. We know they mark a new era in the history of surgical gynecology, and demonstrate the fact that diseases heretofore considered incurable are subject to the skill of the healing art.

In the annals of American surgery the name of Sims will stand side by side with that of McDowell, and, wherever scientific medicine is known, there will his name be honored. His was a successful life; and, if we estimate it by the good he has done (and what worthier standard have we?), the measure of his success was very large.

But, Mr. President, the truest and best expression of honor to his skill and memory will not be spoken in our time, but will be heard from the lips of women yet unborn, when in the beautiful park of yonder city they point with pride to the monument a grateful profession have raised, and tell their suffering daughters and sisters, There stands the memorial to Marion Sims, the Woman's Friend.

Z. T. EMERY, M. D., *Secretary*.

NEW YORK ACADEMY OF MEDICINE.

Meeting of March 21, 1884.

FORDYCE BARKER, M. D., LL. D., President, in the chair.

Dr. HAMLIN, of Auburn, was invited to take a seat on the platform.

LOCOMOTOR ATAXIA AND SYPHILIS.—Dr. LEONARD WEBER read a paper on this subject, in which he first reviewed the general statistics and the opinions of authors concerning the possible connection between locomotor ataxia and syphilis. The percentage of cases of locomotor ataxia in which syphilis was present, according to different authors, varied greatly; commencing from below 18 per cent., we had 18, 20, 21, 70, 80, 88, and 91 per cent. The two latter numbers were those of Erb. Some degree of variation in statistical figures could easily be accounted for, but such as existed here threw doubt upon the value of this method in determining the etiological relation of syphilis to posterior spinal sclerosis. Pathological observations had not definitely proved this relationship. Dr. Weber thought it not improbable that in constitutional syphilis the irritation of the syphilitic poison might start such an inflammation as would lead to the lesions which had been found in posterior spinal sclerosis when other conditions were favorable for its development. He himself had found syphilis as an etiological factor less often than several other conditions. The most common was rheumatism. Masturbation in early youth, and continued for some time, exerted a very baneful influence upon the nervous system in both boys and girls, and laid the foundation not only for so-called nervous affections, but for organic disease. The author had had a few cases of locomotor ataxia in the history of which masturbation in early youth was found to have been a prominent feature. Spinal tabs, from a pathological and a clinical standpoint, was rather a protean disease. So far as his own observations went, in those cases in which there was also a history of syphilis benefit was derived from antisyphilitic treatment, and in some cases the benefit was quite marked, but there had not been a complete cure in any case. Authors, how-

ever, had reported a few cases in which the symptoms entirely disappeared under antisyphilitic treatment. In cases in which a syphilitic history was present, the prognosis, so far as some degree of improvement in the symptoms was concerned, was usually better than in other cases, but the therapeutic results even in such cases had fallen far short of the anticipations of the positivists.

Dr. Weber's experience, with syphilis had convinced him of the importance of taking the disease early in hand, and of following up the treatment persistently for years, if the individual wished to escape the tertiary effects of the disease, and among others the baneful influence which it often had upon the cerebro-spinal system. When a syphilitic history was present in a case of tabes, mercury should not be given by the mouth, but by inunction, the latter method being far more efficacious and speedy in its action. The following statistics were given, based upon his experience with syphilis: The whole number of cases treated was one hundred and thirty-four, of which number one hundred and fifteen were in men, and nineteen in women. None of them were under observation less than four years, and most of them eighteen to twenty years. The details of one case were given, the only case which he had ever seen in which there was a distinct history of syphilis occurring twice in the same individual. The last initial lesion appeared five years after the first. Of the one hundred and thirty-four patients, eighteen, or 13.5 per cent., had, up to the present time, presented symptoms of specific lesions of the cerebral nervous system; eight of the eighteen, of the brain alone. Six of the eight were men, two were women. Five cases were of the brain and spinal cord combined, all in men. Five of the cord only, four in men and one in a woman. Two of the eight patients who had syphilis of the brain alone died of cerebral symptoms. The other six were still alive, but not cured. Of the five with syphilitic affection of the cerebro-spinal axis, two succumbed to the disease; three were still alive. Of the five with spinal syphilis, one, a woman, died of syphilitic paraplegia; four were living, and had been relieved after treatment.

Of tabes he had records of seventeen cases. The first case was a typical one of locomotor ataxia. There was no syphilitic history. The second was a typical case of tabes involving the brain; there was a history of venereal excess, and syphilis was suspected. In the third case there were rheumatic influences, but absence of syphilis. In the fourth case there was typical tabes, but absence of syphilis. In the fifth case the patient contracted syphilis after having had tabetic symptoms many years. Rheumatic influences were the most important in the ætiology. In the sixth, a typical case of tabes, there had been venereal excess; syphilis suspected; there were rheumatic influences. The seventh was an atypical case, with a history of rheumatic influences, but not of syphilis. The eighth was an atypical case, early masturbation being a presumable cause; there was no syphilis. The ninth, a typical case, ended in death from cardiac disease. The cause was early and long-continued masturbation; there were rheumatic influences, but there was no syphilis. The tenth, of the spinal type, was caused by venereal excess. There was no syphilis. The eleventh, atypical in form, was of the spinal type. There were rheumatic influences, but there was no syphilis. In the twelfth, an atypical case, there was no syphilis, but probably venereal excess. The thirteenth was a typical case of the lumbar type; syphilis played the most important, perhaps the only part. The patient improved promptly under antisyphilitic treatment. In the fourteenth, an atypical case, there were none but rheumatic influences. In the fifteenth, a slowly progressive case of typical lumbar type, there had been syphilis twenty years before, and venereal excess for many years; improvement followed the use of galvanism and hydropathy. The

sixteenth was a typical case of tabes; there had been early masturbation, and afterward prolonged physical exertion, but no syphilis. Improvement resulted from galvanism and hydropathy. The seventeenth, a typical case of tabes involving the entire cerebro-spinal system, terminated in dementia paralytica, of which the patient died. There was an undoubted history of syphilis.

The author drew the following conclusions: *First.* There was not sufficient evidence to show that syphilis might be the direct cause of a typical form of locomotor ataxia, in other words, of posterior sclerosis of the cord.

Second. There was proof, and plenty of it, that syphilis produced certain lesions in the cord and its meninges as surely, if not as frequently, as in the brain, that these lesions might be, and often were, followed by symptoms of tabes, and that they were generally relieved by prompt and energetic specific treatment, but rarely cured.

Third. Experience had shown him that the tendency of the syphilitic virus to produce lesions in the nervous centers occurred the sooner the less its course was interfered with by judicious and long-continued antisyphilitic treatment. Older cases were more apt to develop neuroses than those of recent date.

Fourth. As shown by all observers, after syphilitic lesions of the cerebral nervous system were once established, they might often be relieved, but seldom if ever cured, by specific measures. Thus we had reasons in cases of syphilis for insisting upon long-continued and timely treatment, for keeping accurate and judicious watch over the patient, and for attending to specific symptoms as early as possible.

Fifth. The inunction treatment with mercury in fresh cases of syphilis was the best means of reducing the disease to an early and harmless latency.

The President said that, for the purpose of bringing out some remarks on certain points, he would venture to detain the audience a few minutes by referring to three cases which had come under his care, and which were very vividly brought before his mind by the paper of the evening. Although the author had inferentially shown the value of therapeutic results in throwing light on the pathology, he had not emphasized this point in such a way as, to the President's mind, it had been emphasized by personal observation, especially in another class of disease. In brief terms he would mention three cases in which the therapeutic results had led him to believe, and to feel a strong conviction, that the locomotor ataxia was the result primarily of syphilitic poison in the system.

The first case occurred in 1873, in the person of a young man, unmarried at that time, who sent for him on account of what he called rheumatism. He had been gradually finding that he could walk with difficulty, and he suffered from severe pains in the ankle joints—symptoms which gradually increased until he was unable to walk. At last there was complete paraplegia—entire loss of motion and sensation in the lower half of the body—and paralysis of the bladder and rectum. While he had been exposed to venereal trouble, there was no history of syphilis. Syphilis being suspected, however, fifteen-grain doses of iodide of potassium, with a sixteenth of a grain of corrosive sublimate, were given, the iodide being gradually increased until two drachms were taken daily. Within two months the patient began to regain control of the extremities and of the bladder and rectum; after two years he considered himself in excellent health and got married, and had remained healthy since until very recently, when he had bronchitis, and suffered, as was stated, a good deal from his old rheumatism.

The second case was that of a man of fifty-five years, who had bad syphilis in early life, but had remained in good health until the staxic symptoms began to develop. He was put upon

antisymphilitic treatment, and recovered from the ataxic symptoms.

The third case was that of a surgeon in the late civil war, who two years ago began to suffer from difficulty in locomotion, and finally from paralysis on the left side. He denied having had primary disease, but, being thoroughly convinced that his condition was due to syphilis, Dr. Barker gave iodide of potassium and corrosive sublimate, and, as in the other cases, the incidental treatment which symptoms might demand. At that time there was paralysis of one side, with inability to articulate and disturbance of the mind. The rapidity of recovery was marvelous; within one month he could walk, the appetite returned, he gained flesh, the mind cleared up, and he was now apparently perfectly well. It would be evident that the President referred to cases in which there were symptoms of locomotor ataxia, without his attempting to draw a distinction as to types of the disease.

Dr. R. W. AMIDON wished only to put himself on record as one of those who were opposed to calling typical locomotor ataxia a syphilitic disease. Those who held the view that locomotor ataxia was due to syphilis generally founded their opinion upon statistical data, and, as shown by Dr. Birdsall in a paper before the American Neurological Society last summer, and by others, this was a doubtful foundation. Only about nine and five tenths per cent. of the cases, according to Dr. Birdsall's statistics, showed a possible connection between tabes and syphilis. Dr. Amidon had never seen a case of locomotor ataxia, in which he felt satisfied there was sclerosis of the posterior columns of the cord, benefited by antisymphilitic treatment. He thought that, if we wished to acquire light on the subject, we should have to look to pathological anatomy. Syphilis was more apt to attack the membranes than the substance of the brain and cord, and most authors agreed that in posterior sclerosis the contents of the nerve tubules were first affected. The course of the disease was against its being syphilitic; it was slow and progressive, while the course of most tertiary lesions was rapid. What experience he had had, both in the way of treatment and the study of the literature and the pathology of the disease, all went in one direction, namely, against the theory that locomotor ataxia was a syphilitic lesion.

Dr. R. W. TAYLOR said he was already on record as an opponent of the theory, founded on statistics, of the causation of locomotor ataxia by syphilis, and he was very glad to hear the cautious manner in which Dr. Weber had handled the subject. He reviewed the statistical evidence offered by Fournier and others, and expressed his opinion that it was not well founded; Fournier, for instance, made a specialty of venereal disease, and, naturally, if a patient had syphilis and ataxic symptoms, he would go to Fournier. Again, those statistics were largely retrospective, and not founded upon a critical investigation into the patients' past histories. The lesions of syphilis, as Dr. Amidon had said, usually developed in the membranes of the brain and cord, and did not correspond with the pathology of typical tabes.

Dr. W. R. BIRDSALL had heard only the last part of the paper, but said, with regard to the statistics which had been quoted from his paper, that there were forty-two cases of locomotor ataxia in which particular inquiry was made with regard to the presence or absence of syphilis. The number in which there was a syphilitic history was only four, or about 9.5 per cent. The average deduced from the statistics of various authors was about 43 per cent. While we should not ignore these statistics, he thought that up to the present time they were not sufficiently large to be of very definite value. Another fact might be mentioned: that Erb did not recognize the duality of the venereal sore, and this would account in part for the large

number of cases in which he found a syphilitic history. Still, it was somewhat remarkable, after all allowance had been made, that there should have been evidence of syphilis in so many of the cases reported by Erb and others. He himself was disposed to think that syphilis might produce such an effect upon the nervous system as, like venereal excess, great fatigue, and other conditions, to predispose to spinal sclerosis. It also seemed to him that, where there was an incipient sclerosis of the posterior columns, syphilis coming on afterward might be made worse by it. An important point suggested by the President was with regard to what should be called locomotor ataxia. He believed that there were a great variety of affections of the cord in which there was locomotor ataxia, so far as the symptoms were concerned, but in which there were also other symptoms, and other portions of the cord were affected than the posterior columns alone—the lateral columns, for instance—in which there was a variety of other symptoms, which were often confounded with those of true sclerosis of the posterior columns. He believed that an anatomical division was an important one to make.

Dr. E. L. KEYS thought the statistical element could not be entirely ignored when so many men of intelligence and high position agreed to give it some weight. Although he did not believe that pure and simple sclerosis of the posterior columns, if there was a distinct pathological lesion of that kind which characterized pure locomotor ataxia, could or ought to be caused by syphilis, still he thought it perfectly possible that meningeal and progressive troubles in the lumbar columns, and disseminated throughout, might be caused by syphilis, and might be attended by signs of locomotor ataxia. He mentioned one case in which there were unmistakable evidences of syphilis, and at the same time the patient suffered from paraplegia, wasting of the muscles of both lower extremities, inability to walk, paralysis of the bladder, etc. Under antisymphilitic treatment the wasting of the limbs and other symptoms of syphilis disappeared, but the symptoms due to the ataxic lesions continued and he died. In another case also, treated for syphilis, the cerebral symptoms due to that disease had disappeared, and since then distinct ataxic symptoms had appeared. He proposed to put the patient upon active treatment. He was inclined to attach some weight to the idea that pre-existing syphilis might be an active factor in the production of ataxic symptoms. He had seen two or three cases greatly improve under the use of iodide of potassium and inunctions of mercurial ointment. One patient took the treatment with the iodide of potassium badly, and a change was made to mercurial inunctions, etc., and he then improved decidedly in the ataxic symptoms and in general health.

Dr. A. McLANE HAMILTON thought a distinction should be made between posterior spinal sclerosis and cerebro-spinal syphilis. In the cases in which there were the classical symptoms of true locomotor ataxia he had not found a history of syphilis in more than twelve per cent. In the irregular ataxic cases, however, in which there were head and speech symptoms, etc., syphilis played an important part, and these patients were greatly benefited by iodide of potassium—if necessary, given in very large doses, two or three hundred grains a day, in a mild alkaline water.

Dr. F. N. ORIS thought we should not ignore the comprehensive statistics, given by different authors, going to show the presence of syphilis in so many cases of locomotor ataxia. His own experience had been comparatively small, but it had led him to believe that locomotor ataxia could be more readily produced in the way in which some syphilitic troubles were produced than in any other way. Looking upon it as a disease of the connective tissue, a sclerosis from cicatrization of connective tissue accumulation, producing strangulation of the nerve-fibers, it would be found that the disease which produced locomotor

ataxia acted exactly as we knew syphilis to do, and in the same order of events. If it were said that antisyphilitic treatment often had no effect upon tabes, it might also be said that it did not greatly affect certain syphilitic lesions which had gone to an advanced stage. He related the case of a patient sent by him to an eminent specialist in diseases of the nervous system, who pronounced the condition undoubtedly one of locomotor ataxia, and advised ergot, and afterward galvanism. As the ergot deranged the digestion, Dr. Otis finally concluded to employ antisyphilitic treatment, and he also divided the constricted meatus. The patient was soon able to walk with scarcely any difficulty, and his bladder trouble almost entirely disappeared in a few weeks. He thought it safe always to try iodide of potassium and mercury, as it was perfectly safe to do so even for diagnostic purposes.

Dr. E. C. SPRITZKA said an important point had been overlooked to-night, namely, that syphilis undoubtedly affected the central nervous axis in its secondary period. He had known it in a few cases—and others had noted the same fact—to abolish the tendon reflex. If syphilis in the secondary stage was capable of producing this effect upon the nervous system, might it not produce the same effect in the tertiary period in the manner in which this symptom appeared in locomotor ataxia? It had been asserted that the lesions of syphilis were characteristic and distinct, and had not been found in locomotor ataxia. He would deny that *in toto*. He believed it to be perfectly well established that syphilitic meningitis differed in no respect from ordinary meningitis, and most recent investigators of the subject also denied that any marked line could be drawn in the lesions of locomotor ataxia. In his private practice, where he could rely upon the statements of his patients, he estimated that two thirds of the cases of locomotor ataxia had a syphilitic history. It had been shown in the discussion to-night that, where there was a history of syphilis, it nearly always occurred some years before the development of locomotor ataxia, and this we should expect, for, if specific disease could give rise to tabes, it would do so in its tertiary stage. Again, locomotor ataxia occurred more commonly in that class of persons in whom syphilis was most frequent, namely, the inhabitants of cities. He was of the opinion that syphilis was the ætiological factor in about one third of the cases of locomotor ataxia.

NEW YORK SURGICAL SOCIETY.

Meeting of March 11, 1884.

ROBERT F. WEIR, M. D., President, in the chair.

SPECIFIC MYOSITIS OF THE GASTROCNEMIUS.—Dr. F. LANGE presented a patient whom he first saw about three weeks ago. At that time there was a tumor in the calf of the left leg. The difference in the circumference between the two calves was at the lower part 12 cm., while at the tuberosity of the tibia it was about 5 cm. Some of the symptoms led Dr. Lange to assume that it might be of a specific nature. He treated the patient accordingly, and the tumor had diminished considerably in size. He intended to present the patient at a future time, in order to see whether the result of treatment would be such as he expected. He regarded it as specific myositis of the gastrocnemius, extending as high as the upper attachment of the internal belly of this muscle, so that it could be traced into the popliteal space behind the hamstring muscles. The initial lesion occurred fifteen years ago. No secondary symptoms followed, but the patient afterward suffered from a rheumatic affection, located particularly in the clavicles and sternum. These so-called rheumatic attacks were repeated often, but were always treated successfully by the internal administration of iodine. There had

never been any affection of the throat or mucous membranes. For a number of years a stricture had existed, which Dr. Lange had located in the prostatic urethra, and it was yielding to the use of bougies. There was also sclerotic thickening of the skin of the pubes, with central depression and peripheral infiltration. The inguinal and other glands, especially the cubital, were enlarged. There was also a deep depression of the skin of the affected calf, but there had not been any ulceration, as the patient stated. Dr. Lange thought probably there had been a subcutaneous gumma, which had undergone softening with subsequent subcutaneous cicatrization. The scar was pigmented, and presented the characteristic appearance of a specific scar. The patient himself traced the origin of the tumor to a small, round nodule, which could be felt beneath the skin five years ago in the neighborhood of the scar, and had gradually increased in size. The treatment had been energetic, consisting of daily inunctions of four grammes of mercurial ointment, and at the same time the patient had taken iodide of potassium and mercury internally, according to Ricord's formula. For about seventeen days the tumor had been diminishing in size, and was now considerably smaller than when the patient first came under observation. At that time the calf was monstrously enlarged and somewhat œdematous, and at its lower portion there was slight redness of the skin with elevation of temperature. While it could be made out clearly that the tumor belonged to the muscular substance of the gastrocnemius, especially in its inner portion, there was still present a slight diffuse thickening of the surrounding parts which made a thorough, distinct palpation of the boundaries of the tumor impossible. The circumference of the calf had already decreased by 5 cm. in the lower part and 2.5 cm. in the upper, corresponding to the tuberosity of the tibia. The tumor itself could be traced more distinctly as a lengthy, hard mass, which was divided into two portions by a slight depression. This relation could only be made out a number of days ago. At no time had there existed any considerable functional disturbance.

He had also seen a gummatous tumor as large as a goose's egg, which occupied the tendon of the biceps femoris, and, under specific treatment, disappeared entirely.

The PRESIDENT said he had seen a similar infiltration in the sterno-cleido-mastoid and also in the coraco-brachialis muscle, but not of equal size. He asked Dr. Lange if any of the methods by which he determined the location of the stricture in the prostatic portion of the urethra embraced the passage of a full-sized sound to the point of obstruction, with a coincident rectal examination, to determine whether the obstruction was in the prostatic urethra. It was the great rarity of the occurrence of stricture in this portion of the urethra that led him to ask these questions.

Dr. LANGE said he had not resorted to the method last mentioned by the President, but that he located the stricture by simply introducing a bougie, which passed in readily up to the point of obstruction, the latter being located so far behind that it must be in the immediate vicinity of the neck of the bladder. The patient for a number of years had noticed a diminution in the size of the stream of urine, which within the last few months had been reduced nearly to a dribble.

RUPTURE OF THE TENDON OF THE QUADRICEPS FEMORIS.—

Dr. W. T. BULL presented a case which had been treated by Dr. Charles A. Jersey. The man was injured on November '22, 1883, by having the leg forcibly flexed. He was seen within ten minutes after the injury, and a dressing of cotton with a posterior splint was applied to the leg. Twelve hours later this dressing was removed. There was slight swelling around the knee joint. The anterior surface of the thigh was ecchymotic almost to the groin, and there existed a well-

marked depression almost two inches above the knee, probably three inches in width. The power of extending the leg was lost. Three long strips of adhesive plaster were passed around the thigh at different points, in a figure-of-eight form, making traction in the direction of the knee, and approximating the two torn edges of tendon. A Canton-flannel roller was applied from the toes to the groin, and a plaster splint from the ankle over all. The thigh was held at almost a right angle to the body during the application of the entire dressing. The leg was left in this appliance for forty days. After the third week the patient was permitted to go about on crutches. At the end of forty days, the splint having become somewhat softened, a new one was applied, the adhesive plaster strips and the Canton-flannel roller not being disturbed. This second splint was left on for twenty-one days, the patient during the last week being permitted to walk about without crutches. At the expiration of this time the entire dressing was removed, a posterior felt splint with a bandage from the toes was worn for one week, and then a rubber bandage was applied, which the patient had worn up to the present time. He used a cane until about the 10th of February. Now, three months and a half from the receipt of the injury, the man had a very useful limb, flexion of the knee being possible to three quarters its normal extent, and extension perfect and strong. There was much thickening of tissue about the seat of injury, but no sign of the defect usually seen beneath the skin after rupture of the belly of a muscle.

He had seen several cases of this injury, and in but one was there finally any power of extension whatever; that was a case in which it existed six months after the injury, and only the fibers of the rectus were torn. As a rule, in an injury of this description, the patient lost the power of extension, and Dr. Bull had been led to regard it as a far worse injury, so far as the functions of the knee joint were concerned, than fracture of the patella. He knew of two persons in whom rupture occurred upon both sides, and both had since been obliged to wear artificial supports to enable them to walk.

Dr. C. T. POORE had had a case in which rupture occurred on the right side, and there was separation to the extent of about four inches. The patient recovered, and was now able to walk without artificial support, had no limp, and could bend his leg, the only apparent defect being that the extensor muscle was not quite so strong as the other. He treated it by the use of a plaster-of-Paris splint, with a strip of adhesive plaster over the course of the muscle to hold it down at the point of rupture. There was ultimately about three inches of new tendon formed.

The PRESIDENT had met with five cases of this injury within the past two years. In only one was the rupture complete, and he was inclined to believe that in the majority of cases the injury was confined to the central tendon, and that in such cases the prognosis was much better in the one torn completely across, which was only seen several years after the accident; there was little or no difficulty in the patient's walking, and no posterior splint was required. All the other cases were treated by the approximation of the divided ends of the muscle by means of strips of adhesive plaster over the thigh anteriorly and fastened below to the sides of the leg, and the use of plaster-of-Paris bandage. He had at present a patient, whom he hoped to show at the next meeting of the society, in whom both quadriceps tendons had been torn across at the same time, and in whom recovery was nearly complete. In all his cases the injury was the result of muscular action.

ON THE TREATMENT OF FRACTURES OF THE PATELLA BY THE PLASTER-OF-PARIS SPLINT.—Dr. JAMES L. LITTLE read a paper with this title. [See p. 345.]

The PRESIDENT asked, in presenting Dr. Little's paper for discussion, what experience, if any, had been obtained by the

members of the society in the treatment of recent fractures of the patella by aspirating the joint for blood effused within it, which had been said to be one of the causes of separation of the fragments. Mr. Heath, of London, and other surgeons, had spoken of this method as being serviceable. In the recent discussions which had taken place in Great Britain, arising from Sir Joseph Lister's notable paper on fracture of the patella, the point had been made that one of the reasons why bony union did not take place in fracture of the patella was that little fragments of fibrous tissue were caught between the ends of the broken bone. Macewen, of Glasgow, also alluded to this fact, having proved it in one or two dissections. If aspiration allowed the fragments to be apposed, it would seem to be sound surgical practice, in order to get rid of this small amount of interposed fibrous tissue, to rub the fractured surfaces briskly together for a few moments before applying a splint.

Dr. H. B. SANDS doubted whether, in average cases of fracture of the patella, marked superiority could be claimed for any single method of treatment, all methods being more or less imperfect. The treatment recommended by Dr. Little resembled very closely the common one, which consisted in placing the limb upon a straight posterior wooden splint and applying straps of adhesive plaster obliquely above and below the fragments. He had for many years believed that the extent of primary separation of the fragments depended mainly on two causes, namely: laceration of the fibrous tissues, and distension of the knee joint with blood or inflammatory effusions. He deprecated the premature and forcible attempts often made to approximate the fragments while the joint was distended, believing that such treatment was liable to increase their separation by causing further effusion. He quite agreed with Dr. Little in recommending that, until the subsidence of the swelling, treatment should be restricted to rest of the limb in an extended position, the use of some evaporating lotion, and, when necessary, moderate pressure by means of a flannel or elastic bandage. He remembered having read, many years ago, of cases treated in St. Bartholomew's Hospital by simply placing the limb at rest in a straight position upon a posterior splint. Approximation of the fragments occurred spontaneously when the swelling subsided, and very good results were obtained, the uniting medium, although ligamentous, being generally very short. It seemed to him that by the method recommended by Dr. Little, although good results would often be obtained, there might sometimes be found a liability to a tilting of the fragments. Dr. Sands had endeavored to obviate this difficulty by resorting to a method practiced by many surgeons, in which strips of moleskin adhesive plaster, attached to the limb above and below the seat of fracture, were brought together and fastened by a buckle directly over the broken bone. Of course, it was presumed that, when Dr. Little spoke of approximating the fragments, he meant an approximation of the upper to the lower fragment, as no amount of force was capable of stretching the ligamentum patellæ. Dr. Sands had also, in some cases, resorted with advantage to Malgaigne's hooks, the points of which were prevented from penetrating the skin by the interposition of several layers of thick adhesive plaster. This practice, he believed, originated with the late Mr. Spence. He was a little doubtful whether, in bad cases of fracture of the patella, attended with great separation of the fragments, any treatment would produce good results short of a surgical operation. He was convinced, however, that, in a majority of cases, many forms of apparatus could be used which would enable the patient to obtain a useful limb.

Dr. BRILL said, with regard to the plaster-of-Paris bandage as distinguished from the plaster-of-Paris splint in the treatment of this fracture, that he thought Dr. Little had expressed himself adversely to the plaster-of-Paris bandage a little too strong

ly. It had certainly been thoroughly tested in New York hospitals, and was now generally used in a number of institutions, and he thought the results obtained did not justify the expression that it might be justly condemned. With regard to this application in the treatment of fracture of the patella, it was the only apparatus which he had used. He had regarded it as the simplest form of apparatus that would keep the knee absolutely still, and one which was more easily applied than the apparatus described by Dr. Little. Before applying the plaster bandage he always drew the upper fragment down as far as possible with the hand, and held it there by means of a single strip of adhesive plaster, while a second strip served to steady the lower fragment. He had met with a good many cases of fracture of the patella during the last six or seven years, and he had yet to see one in which the upper fragment could not be approximated to within one fourth to one inch of the lower fragment within a certain time. He said a *certain time*, because this period varied a great deal according to the quantity of effusion into the joint. He had seen two cases in which the upper fragment could be drawn down directly, and there the plaster splint was applied within a few minutes and allowed to remain until the bone had united by ligament. He had not seen any cases in which the union was entitled to be considered as bony union.

It had been suggested some years ago that the disappearance of the effusion could be accelerated by aspiration, and Schede had proposed puncturing, washing the joint out, and then treating the puncture with antiseptic dressing. Dr. Bull had had no experience with the latter method, but he had tried aspiration in two cases. In both he aspirated the joint twice, because the first operation did not facilitate the approximation of the fragments, although a small quantity of bloody serum was withdrawn. The second aspiration was about as futile as the first. He had almost reached the conclusion that the best method was to allow the effusion to subside, aiding absorption only by firm compression, such as could be made by a firmly applied cotton dressing over the entire limb (laid on a Volkmann's splint). He had resorted to that measure where there was a good deal of effusion, and at the end of a period varying from five to ten days the upper fragment had been approximated within one quarter to one inch of the lower one with great facility. With such a ligament, if not stretched by flexing the joint too early, the joint functions would be satisfactory.

It seemed to him that no one who had had experience in the use of the apparatus recommended in Hamilton's "Surgery" would wish to use it a second time, because it required constant attention, and the bandages must be renewed every day, or at furthest every second or third day. While he believed the apparatus described by Dr. Little was certainly safer for surgeons not experienced in the use of plaster of Paris in the shape of a bandage, he thought the plaster bandage safe enough for any man who had had reasonable experience in the application of bandages in general to the extremities.

Dr. LANGE had observed a number of cases in which separation of the fragments existed years after the injury, varying from an inch and a half to two inches and a half, and in which the limbs were entirely useful, the power of extension was complete, and the patients were able to go up and down stairs without the slightest discomfort. He had treated a number of such cases, and among them were two in which fracture of the patella took place several times, besides one in which separation of the tendon of the quadriceps took place where a gap existed now sufficiently large to allow of the interposing of the hand, yet without functional disturbance of the leg. It seemed to him that after a time the lateral part of the capsular ligaments took up the function of the muscle to a certain extent.

Dr. GEORGE A. PETERS had seen one case of fracture of the

patella with separation of the fragments to the extent of two inches, and the patient had perfect use of the limb and was even able to skate.

Dr. BULL said Dr. Little had justly emphasized the fact that bony union was not necessary for a useful limb, a fact frequently overlooked by those who had advocated wiring of the patella. He knew of one policeman and one fireman, who at the present time were on active duty, who had ligamentous union of a fractured patella. In one case the ligament was about an eighth of an inch long at the first, but it gradually lengthened until the fragments were separated to the distance of one inch, and yet the man was not aware of the fact.

Dr. POORE asked if the question of ability to walk was not one of ability of the patient to use the muscle attached to the ruptured tendon. He thought the disability consisted not so much in the separation of the fragments as in the weakness of the muscle which was attached to the upper fragment, and that the difficulty in walking was due to the impossibility of the patient's getting accustomed to use the shortened muscle.

Dr. LITTLE said that the lower strip of plaster in his apparatus was simply to steady the lower fragment, while the upper fragment could be brought into the closest approximation. With regard to the difficulty in walking with a long ligamentous union, he thought a distinction should be made between the power of extending the leg and the ability to walk. Patients with a long ligament uniting the fragments were often unable to make complete extension of the limb, but they were able to walk without difficulty. In a recent case, where he applied his splint at the Post-Graduate School, Dr. Powell, who had the case in charge, assured him that he found the patient the day after the accident walking about her room with the aid of a cane.

About a year ago Dr. Stinson had presented a case before this society in which the patient had had each patella torn from its ligament, and no union had taken place. This man could not extend his legs, but was able to walk about with but little difficulty.

Another point of interest in connection with fractures of this bone was the liability of the opposite patella to suffer from a similar injury. He had seen a number of cases of this kind. In all these fractures were caused by muscular action. This was generally attributed to the greater strain upon the sound bone and the greater liability of the patient to fall. In two cases which had come under his notice the patients had told him that they had suffered a certain amount of pain in each patella before the fracture took place. He had never seen a patient in whom the fracture was caused by direct violence who afterward suffered from a fracture of the other patella. It was possible that the true explanation of these cases was that they were caused by an abnormal condition of the bone at the time of fracture. The slight amount of force which caused the fractures in both of these cases, and the pain in the bone felt before the occurrence of the injury, would seem to point in that direction.

Dr. BULL asked Dr. Little with regard to passive motion and the advisability of resorting to it, as mentioned in his paper.

Dr. LITTLE said he had simply quoted Dr. Hamilton.

Dr. BULL said he had always felt that it was not the right thing to resort to passive motion. One should always aim to obtain a short and very strong ligament, and he had always abstained from allowing the patient to move the knee joint for at least ten or twelve weeks; and by the end of the eighteenth or twentieth week the movements had been satisfactory, and the joint had been strong.

TRAUMATIC RUPTURE OF THE TRACHEA.—Dr. LITTLE presented a trachea removed from a man sixty years of age, who had died in St. Vincent's Hospital, having been struck in the neck

and upper part of the sternum, on Saturday last, by one of the shafts of a truck. When he first saw the case, five hours after the injury, he found the patient emphysematous from the head to the lower part of the abdomen. There was considerable ecchymosis over the sternum, but no difficulty in breathing, and no cough. There was pain on pressure over the upper part of the sternum and over the trachea. There had been slight expectoration of blood before the man entered the hospital. The emphysema was greater over the chest than elsewhere, and less about the neck. Injury of the trachea was suspected, and the patient was anesthetized and a careful examination was made over the trachea and larynx, but no injury of these parts could be detected. As there were no symptoms of suffocation, it was thought best not to perform tracheotomy. The patient gradually sank, however, and died this morning, sixty hours after the injury.

There had been considerable cyanosis during the last twelve hours, but no symptoms of suffocation. The autopsy showed a complete separation of the fourth and fifth rings of the trachea, with signs of recent inflammation and hemorrhage in the surrounding tissues. Double hypostatic pneumonia and pleuritis also existed.

FLOATING CARTILAGE IN THE KNEE JOINT; REMOVAL.—Dr. LITTLE also presented a specimen of floating cartilage which he had removed from the knee joint of a patient who had come under observation three weeks ago, having suffered from slight pain in the knee for ten years. About six weeks ago he noticed symptoms for the first time indicating the presence of a loose cartilage, and, on examination, a movable body was discovered, which was quite prominent. On the 28th of February last Dr. Little removed it under strict antiseptic precautions. The operation was performed as follows: A bandage was applied from the leg to a point just above the patella, so as to keep the loose cartilage in the upper part of the joint. It was then "fixed" at a point on the outer side of the joint by a strong acupressure needle passed through the tissues. An incision was made, and the cartilage was removed by a pair of bullet-forceps. The edges of the wound were brought together by two catgut sutures, the wound of the synovial membrane not being included in the sutures. A compress of iodoform gauze and a full Lister dressing were applied. The patient did well until the morning of the fourth day, when he had a chill and a sudden rise in temperature (to 102° F.). On removing the sutures, about half an ounce of pus escaped from the wound. The synovial cavity was found to be slightly distended, but no fluid could be pressed from the joint through the wound. Believing that the collection of pus was external to the joint, Dr. Little reapplied the dressing, in a few hours the temperature subsided, and in forty-eight hours the effusion disappeared from the joint and the patient made a rapid recovery.

Dr. BULL had removed three of these cartilages. In two cases he put in no sutures, and the result was satisfactory. In the third case he used sutures, and the man had a very troublesome effusion which lasted for six months, coming and going. He employed catgut sutures, and they were introduced through the capsule.

Dr. SANDS had performed within the last six months three operations upon the same patient, the right knee being operated upon twice and the left knee once. In each case the operation was performed in the same way, the joint being directly incised, and the edges of the cutaneous wound being united by a suture after the removal of the floating cartilage. Bichloride solution was the antiseptic employed, and peat was used as a dressing. In all the cases primary union took place without rise of temperature and without effusion into the joint.

Dr. A. G. GERSTER had also had occasion to operate upon

three patients, in two of whom there were three movable bodies, one of which could be proved to have been chipped off from the tibia; the second was a smooth, almond-shaped body, the origin of which could not be ascertained; and the third he was obliged to manipulate for considerably, and it was found that several small bodies were attached by pedicles to the ligamentum alare, near the inner margin of the patella. These growths had to be extirpated from their attachments, and it became necessary to tilt up the patella and expose its lower surface for this purpose. In all three cases the joint was washed with a five-per-cent. carbolic-acid solution, it being before the advent of the bichloride solution. In all the cases a supporting suture was applied through the capsule, and after that skin stitches were introduced, and in every case a drainage-tube of small caliber was left in the joint for the purpose of removing as much effusion as might take place, but this tube was removed on the fourth day. In all the cases the dressings were antiseptic and the recoveries were uninterrupted.

THE PRESIDENT had an instance brought to mind by Dr. GERSTER's last case, namely, the presence of fatty growths in joints. Last autumn he cut into the knee joint for the removal of a loose cartilage situated to the inner side of the patella, movable in various directions, but attached somewhere in the region of the patella, and of about the size, as felt through the skin, of the end of his little finger. On reaching it, it was recognized as being not of the usual cartilaginous formation, but softer, and it proved subsequently, on microscopical examination, to be fibrous tissue with fat. It was analogous to the fatty growths which Barwell had described and had removed successfully from the knee joint. Volkmann also spoke of similar troubles in the same joint. In his case considerable manipulation of the joint was resorted to in the removal of the foreign body, and, although all antiseptic precautions were used, the wound and joint being washed out with sublimate solution 1 to 5,000, and a drainage-tube inserted, the case did badly, and suppurative of the joint and of the tissues about the articulation took place. Septicæmia developed, making it necessary to amputate the thigh, which was done after Neuber's method, with rapid healing. The process of inflammation had, however, so destroyed the tissues of the joint that he was unable to demonstrate anything further concerning the connection which this peculiar formation had with the joint itself, though it was evidently a hypertrophy of the sub-patellar fatty tissues.

He had also since met with one other case of this kind, but he did not operate upon it. He saw last week at his college clinic a woman about fifty years of age who had had symptoms of floating cartilage during the last twenty years. The body was quite large, and was situated at the inner and upper aspect of the joint, and, from the symptoms and from the attacks of its catching between the articular surfaces, he assumed that it was attached by a somewhat long pedicle. The patient was unwilling to have an operation performed, because she suffered but little and the permanent joint damage was not marked. The special point of interest in the case was the rather long time for such a difficulty to have existed without serious impairment of the joint.

Dr. GERSTER asked Dr. Little if he applied a posterior splint after his operation.

Dr. LITTLE said he had neglected to state that he applied a posterior splint after the operation, so that the joint was kept perfectly quiet.

THE PRESIDENT had always employed a splint, and also used firm compression after opening the knee joint.

Dr. SANDS said that in his three cases the limb was placed upon a posterior splint after the operation, and the dressing was not removed for two weeks.

Dr. BULL said that in all his cases he had used the typical Lister dressing and a posterior splint.

Dr. GERSTER said that he also had applied a splint in all his cases.

EPITHELIOMA OF THE LARYNX.—Dr. CHARLES MCBURNEY presented a specimen with the following history: It was removed from a male patient, fifty-nine years of age, who first exhibited symptoms of disease four months ago, the first being a small swelling in the right side of the neck, beneath the angle of the jaw, but it was not until the end of January that any dysphagia was noticed, and there was no dyspnea. When he came under Dr. McBurney's observation in February, the man had a large tumor on the right side of the neck, extending from the angle of the jaw nearly to the clavicle. He was able to speak with quite a clear voice, complaining scarcely at all of difficulty of swallowing, although at times there was some difficulty in swallowing solid food. On examination with the laryngoscope, Dr. McBurney was able to see a large mass apparently filling the entire lumen of the larynx, and the appearance was such that he was unable to account for the excellent voice. He had no means of determining the extent of the growth, although its appearance indicated that it extended down the oesophagus. The patient died on Friday last. He swallowed fairly well up to that time, although there had been steadily increasing dysphagia. The voice remained very good until death. The specimen showed that the true vocal cords were entirely unimpaired.

Dr. McBurney also presented the specimen removed from the neck, which was probably carcinomatous, although the microscopic examination had not been completed. The most interesting feature, perhaps, was the condition of the artery seen upon the back of the specimen, where, near its bifurcation, endarteritis obliterans was apparent, and the vessel just above was firmly attached to the tumor. There was no direct positive union of the two tumors, but he inferred that the laryngeal was the original growth, and that the tumor in the neck was secondary, and one which began in the lymphatic glands.

EPITHELIOMA OF THE CERVIX UTERI; EXTIRPATION OF THE ENTIRE UTERUS THROUGH THE VAGINA; RECOVERY.—Dr. BULL presented the uterus, which was the seat of cancer involving the greater part of the cervix. It was removed, by the vaginal method, on the 17th of February, 1883, from a patient forty-five years of age, who had had symptoms of uterine cancer one year previous to admission to the hospital. At the time of admission the growth formed a large cauliflower excrescence at the upper part of the vagina, and apparently did not involve the body of the uterus. She had not received any treatment. The urine had a specific gravity of 1.020, was acid, and contained a little albumin and a few hyaline casts. The uterus was removed by Czerny's method without difficulty, although the operation was laborious and long, from the care required to dissect the expanded cervix from the base of the bladder. The broad ligaments on either side were secured with two carbolized-silk ligatures and cut between them. The peritoneal wound was loosely held together with four or five silk sutures. Just before the sutures were introduced a mass of intestine or omentum could be seen at the bottom of the wound. In passing the sutures through the peritoneum, hemorrhage occurred from one of the broad ligaments, which was controlled by the hæmostatic forceps, and it was necessary to leave the instrument in position. The wounded surfaces were dusted lightly with iodoform, the vagina was packed with small iodoform peat-bags, and the vulva covered with borated cotton. There was but slight reaction, and at the end of five days the first dressing was made; while there was more or less discharge, there was no evidence of decomposition whatever. At that time the hæmostatic forceps was removed. The further progress of the case was rapid. At

the end of one month the patient was able to sit up, and soon afterward left the hospital. For eight months afterward she continued in very much better health than she had enjoyed for years previous to the operation, and believed herself to be cured. There remained, however, a small spot at the top of the vagina which was not disposed to heal, although her general condition was quite good. About nine months after the operation there appeared a hard nodule on the posterior vaginal wall, which was removed with the curette, together with the small spot previously noticed. For a month afterward the condition of the parts remained unchanged. From the tenth month after the first operation up to the present time the patient's health had slowly declined, and now, nearly thirteen months after the first operation, she was worse than at the time she first entered the hospital. She had a pelvic tumor of about the size of a child's head, and had the distressing abdominal symptoms which usually accompanied this condition. Yet there had been no offensive discharge from the vagina, nor hæmorrhage.

In two other cases he had attempted the same operation, but had been unable to get the uterus out with safety, and had simply contented himself with the effort to remove as much as possible, after dissecting the tumor from the bladder and rectum, without opening the peritoneal cavity. Both patients recovered rapidly from the operation, and, though in one the cul-de-sac of Douglas was accidentally opened, he thought the operations had been of much benefit to the patients, especially with reference to getting rid of the offensive discharges and hæmorrhages which almost invariably accompanied cancer of the uterus. One woman, who had had several hæmorrhages before the operation, went six months without any bleeding or abundant discharge, and died a year afterward. The other had been operated on but a few weeks ago.

Dr. LANGE said he had presented to the society one patient from whom he had extirpated the uterus totally for sarcoma two years ago. About six weeks ago he saw the patient, and she was apparently entirely healthy. In two other cases in which he had performed the supra-vaginal amputation, one for a very large myxo-sarcoma, and the other for a large fibroma, the patients were still quite well; one sixteen months, and the other nine or ten months after the operation.

SARCOMA OF THE KIDNEY.—Dr. LITTLE presented a specimen which he had removed at St. Luke's Hospital by operation, on September 11, 1883, from a girl four years old. According to the mother's statement, the child's abdomen had been swollen and hard from birth. One month previous to her admission this enlargement began to increase rapidly. On examination, the abdomen was found to be greatly distended, very tense, and fluctuating, and the subcutaneous veins over the surface were enlarged. The enlargement of the abdomen was so great that it prevented the child from walking or standing. There was marked dullness on percussion over the right side of the abdomen, extending several inches beyond the median line. From this point it was tympanitic. A distinct tumor could be felt occupying the entire region of dullness, extending upward to the margin of the ribs. There was no œdema of the feet. The urine was normal, and the child's general health was good.

On September 15th the tumor was aspirated, and about eight ounces of a dark-red fluid were removed. On examination, it was found to contain blood globules, but no further evidence as to the character of the disease was revealed. A consultation was held, which resulted in a diagnosis of a cyst, probably connected with the kidney (hydro-nephrosis), and an exploratory incision was advised.

On September 25th Dr. Little performed the following operation under strict antiseptic precautions: He opened the abdominal cavity by an incision two or three inches long, between

the umbilicus and pubes, which was subsequently enlarged. A considerable quantity of fluid at once made its escape from the abdominal cavity. The tumor was found situated beneath the posterior layer of the peritonæum, extending from the pelvis up to the border of the ninth or tenth rib, and overlapping the spinal column. A large trocar was passed into the most prominent part, and nearly two quarts of a dark-colored fluid were removed. It was then found that the upper portion of the tumor was solid. The peritonæum covering the tumor was then opened and the growth was carefully enucleated. Its upper part was found to be in such intimate connection with the kidney that it was necessary to remove that organ. A ligature was passed around the renal vessels, and the whole mass was removed. The hæmorrhage during the operation was not great, and was readily controlled. The peritonæum was closed by catgut, and the abdominal wound by silver-wire sutures, and Lister's dressings were applied. The condition of the patient during the latter part of the operation was very feeble, and, although every means to bring on reaction were used, she died from shock about half an hour after the completion of the operation.

Microscopical Examination of the Tumor, made by Dr. FRANK FERGUSON:

"*Small-round-celled Sarcoma, with Cysts.*—The tumor arises from the anterior aspect of the lower end of the right kidney. Its shape is spheroidal, and it measures six inches in diameter. It is surrounded by a fibrous capsule rich in small, round, and spindle-form elements, and continuous with the capsule of the kidney. There are numerous cysts of various sizes throughout the tumor, into some of which hæmorrhage has occurred; but, as a rule, their contents are a clear, serum-like fluid rich in albumin, and a few of the small-round cells of which the tumor is composed. In these cysts are also found kidney tubules and glomerules. Kidney structure is also seen throughout the tumor. The cells which compose the tumor are supported by a delicate frame-work of fibrillated material, and the entire tumor is rich in its vascular supply. The kidney is slightly larger than in subjects of this age, and, on microscopic examination, normal in structure beyond the line of invasion of the morbid growth."

Miscellany.

THERAPEUTICAL NOTES.—*Iodoform as a Palliative for Cancer of the Cervix Uteri.*—M. Castré (Thèse de Paris, July, 1883; "Bull. gén. de thérap.," Feb. 29, 1884) recommends a special perfumed preparation of iodoform as a palliative application in cases of cancer of the neck of the uterus, being the method of treatment devised by M. Gillette. The mixture is composed as follows:

Iodoform	18 grammes (about 270 grains);
Sulphate of quinine.	3 " (" 45 ");
Powdered charcoal.	15 " (" 225 ");
Essence of mint (? peppermint),	40 drops.

Thus prepared, the iodoform may be added to ordinary liquid excipients, but, to avoid its coming in contact with the sound vaginal mucous membrane, the author recommends its use in the form of the powder, applied on tampons of cotton, which are introduced with the aid of a speculum. It is said to be important not to try to cleanse the ulcerated surface before making the application, as the iodoform will do that of itself. The period between the applications may vary from four to ten days.

Iodoform in the Treatment of Aphthous Inflammation of the Vulva.—M. Surazin (Thèse de Paris, July, 1883; "Bull. gén. de thérap.," Feb.

29, 1884) remarks that this affection rarely ends in gangrene if treated with iodoform. Powdered iodoform should be dusted on in a thick layer daily, without any attempt to cleanse the parts, and then a little lint be interposed between the labia. The vulvar affection heals rapidly under this treatment, but when the perineum is likewise affected, although the treatment is equally effective, it is slower.

The Treatment of Acute Delirium.—A writer in the "Union médicale" gives the following summary of the treatment of acute delirium as recommended by M. Ball and M. Chambard: See that the light in the room is moderate, and that the patient is freed from every occasion for excitement or agitation. Give him baths of a moderate temperature during the early period of the attack, and belladonna during the second period. In the asthenic forms of acute delirium, tonics of various sorts should be given, especially the preparations of cinchona in tolerably large doses. Redden the skin by means of sinapisms, mustard foot-baths, and frictions with a harsh brush; act on the bowels with purgative enemata. If the patient refuses food, resort to nutritive injections, and to M. Fernet's procedure, which consists in introducing the tip of a small spoon, made for the purpose, into the nostril, pressing it back gently, and allowing the liquid food to run from it into the nostril, from which it will follow the inclined plane of the nasal fossæ, and fall directly into the pharynx, so that it will be swallowed whether the patient will or no.

Sulphate of Copper as an Antiseptic in Midwifery.—M. Charpentier ("Gaz. hebdom. de méd. et de chir.," March 7, 1884) recently reported to the French *Académie de Médecine* a series of experiments that he had made with sulphate of copper as a preventive of putrefaction, the results of which had convinced him that, in a solution of one part of the salt in one hundred parts of water, the agent was a trustworthy and harmless antiseptic. He had therefore used it as a vaginal and uterine injection at the *clinique d'accouchement*, where there had been no deaths since the 15th of June, whereas for the preceding six months, in the service of the late Professor Depaul, there had been twelve deaths from septicæmia in three hundred and ninety-seven cases of confinement. This happy change M. Charpentier imputes to the use of the sulphate of copper. He urges in favor of this agent that it is perfectly safe, very cheap, easily managed, and an instantaneous disinfectant as well as a powerful antiseptic; also, that its astringent and coagulating properties are such that it may perhaps in the future take the place of perchloride of iron as a hæmostatic, over which it has the advantage of not clogging wounds. The solution should be used warm, of the strength of one part to one hundred. In a number of cases of large thrombus of the vulva the use of this antiseptic was followed by recovery without the formation of a drop of pus, and in a case of foul abscess of the urethro-vaginal septum it overcame both the fætor and the symptoms of putrid infection at once, after carbolic acid had failed.

Nux Vomica and the Mineral Acids in the Treatment of Diabetes.—Dr. S. Wilks, of London ("Med. Times and Gaz.," March 8, 1884), reports three cases of diabetes treated with the use of nux vomica at Guy's Hospital. In all of them the patients gained in weight, and gave other evidences of improvement, although one of them died suddenly some time after leaving the hospital. Dr. Wilks remarks upon the beneficial action of these remedies on the digestion, but he thinks that this action is not sufficient to explain their manifest good effect in diabetes. He is persuaded that, over and above their action on the digestive apparatus, they have a positive effect upon the glyco-genic function. The three patients whose cases are reported were put upon the use of anti-diabetic diet.

THREE REMARKABLE PRESCRIPTIONS.—According to the "British Medical Journal," the following prescription was sent to a druggist "in America": "Gummi camfor, I ownze; lodnom, I ownze; kloryforme, I ownze; oil sassyfras, I ownze." Also this: "Srip of squills, parygaric, oyl of amonds, bolsom pavia, swet sperrit nighter. Give baror a cannl (calomel) powder for agnone persien." A correspondent of the "Lancet" writes a prescription as follows: "R Infusi foliorum rescutium saxifragæ, ℥ iii. [Faciat, ex aquâ calidâ, xviij. Fiat, per horas sex; foliorum i, aquæ x.] Glycerini, ʒi. Misc. Fiat injectionem, ut bis die utendum."

Lectures and Addresses.

THE CARTWRIGHT LECTURES

ON

METHODS OF STUDYING THE BRAIN,

DELIVERED BEFORE THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, FEBRUARY 2, 4, AND 6, 1884.

By BURT G. WILDER, M. D.,

PROFESSOR OF PHYSIOLOGY, COMPARATIVE ANATOMY, AND ZOOLOGY IN CORNELL UNIVERSITY, AND OF PHYSIOLOGY IN THE MEDICAL SCHOOL OF MAINE.

LECTURE III, PART I.

Some Points in Encephalic Anatomy which are not Infrequently Overlooked or Misunderstood.

As announced in the first lecture, the third comprises two parts, dealing, respectively, with (a) certain facts in encephalic anatomy, and (b) methods of illustration and description.

In the choice of anatomical matters, three objects have been kept in view: a. In general, the illustration of the methods described in the earlier lectures; in particular, b. The elucidation of cælian circumscription; and c. The correction or qualification of statements or figures in two English manuals of descriptive anatomy, Quain's and Gray's.*

If any are startled at the intimation of possible imperfection in works to which students refer with confidence, and upon which, it is to be feared, some teachers too implicitly rely, they have only to compare the accounts of the brain in any two similar anatomical treatises, or in different editions of the same. In Quain, for example, so great are the textual and pictorial improvements of the edition of 1882 over that of 1877 that our admiration for the excellence of the one is qualified both by surprise at the defects of the other and by fear lest still further change may be required.

In respect to the macroscopic anatomy of the brain, the shortcomings of the two admirable works above named may be treated as: a. Omissions; b. Inaccuracies; c. Statements or figures liable to cause misconception.

Omissions.—*Bulbus Postcornu*.—As shown in Figs. 44 and 45 (this journal, March 1st), the mesal wall of the postcornu presents not only the calcar, but also, just dorsad of it, an elevation which Henle calls *Bulbus cornu posterioris* (p. 168, Figs. 91–93). It is not mentioned in the last edition of Gray, and in the last of Quain (ii, 346) it is for the first time described but not figured.†

* These works are also edited and republished in America, and are so commonly employed that to confine criticism mainly to them will imply no invidious distinction. Still less does the offering of these criticisms imply upon the part of the critic either an assumption of freedom from error or any unwillingness to be called to account therefor.

† Were I not desirous of showing that progress both has been made and is yet to be made, I should refrain from calling attention to this particular instance. The elevation in question was first observed by me in a brain the cœliæ of which had been injected with alcohol. Having at hand just then neither Henle nor the last edition of Quain,

In view of the obvious relation of the postcornual bulb to the splenium, a constant part, the infrequency of its mention may fairly be ascribed not to its own inconstancy, but to the inadequate preservation of the cælian parietes and the haste with which they are commonly examined.

Cauda Striati.—That the human striatum is prolonged as a slender "tail" following the remarkable curvature of the medicornu and terminating at or near the tip of the latter is indicated in Cuvier's "Leçons d'anatomie comparée," in the editions of 1800–1805 and 1836–1846. The description is in part as follows:

"Ils [les corps cannelés ou striés] se terminent par une queue qui suit exactement le contour de la couche optique et de la racine du nerf du même nom, et ils se terminent en dessous par un élargissement obtus, en sorte que chaque corps cannelé représente un fer-à-cheval, dont l'une des branches serait beaucoup plus grosse que l'autre. Dans la position naturelle du cerveau, ce fer-à-cheval est placé de champ, de manière que la grosse branche est en haut, et un peu plus en avant et dedans que l'autre." (A, iii, 51.)

This feature of the striatum is also described and figured by Reichert (Figs. 31–34), Meynert (Stricker, 681–683, Fig. 256), also, as stated by Dalton (I, 11), by Gratiolet, Todd, and Hirschfeld, and more recently Dalton himself in the paper just mentioned.

In Quain (ii, 351) the *cauda* is described as "passing nearly to the extremity" of the medicornu, but it is not distinctly shown in the figures. In Gray its existence is not recognized at all.

Cimbia (*Tractus peduncularis transversus*, Gudden).—In many mammals there crosses the Crus cerebri, between the pons and the Tractus opticus, a more or less distinct

FIG. 46.—LATERAL ASPECT OF THE LEFT DIEN (THALAMUS, ETC.) AND MESEN (OPTIC, ETC.) OF THE CAT; × 25. DRAWN BY PROFESSOR CLEAVES.

The dorsal end of the *cimbria* is made too distinctly continuous with the postopticus. Some of the fibers seem to pass between the præopticus and the thalamus. The root of the *N. oculo-motorius* should be shown just caudad of the ventral end of the *cimbria*.

fibrous fasciculus. It is constant and very distinct in the cat (Fig. 46), where its ventral end crosses just cephalad of

I rather hastily concluded that it was an undescribed feature, and, at the meeting of the American Neurological Association, in June, 1883, showed the preparation and photographs of it, and proposed for it the provisional name *Eminentia splenialis* ("Journal of Nervous and Mental Diseases," July, 1883, p. 85), based upon the obvious fact that it represents certain splenial fasciculi; this name must be withdrawn in favor of *Bulbus postcornu* until it be ascertained to have received a still earlier and equally appropriate name of a single word.

the root of the *N. oculo-motorius*, and dips suddenly into the substance of the crus.

Even if Henle is correct in stating (p. 148) that this fasciculus is only exceptionally present in man, some reference to it should be made in compendiums like Gray and Quain.*

Even in the cat the *cimbria* might escape notice if the brain were poorly preserved or transected in the usual way. In order to expose it, the corresponding hemisphere must be carefully dissected off with a sharp and narrow-bladed scalpel. In a series of microscopic sections it might, of course, be detected, and even in a macroscopic section which happened to coincide with its direction for any distance, or to divide the part of the crus into which the ventral end abruptly dips.

Striæ longitudinales callosi.—Here may be noted the lack of recognition, not only in the works above named, but in all others that have come under my notice, of the easily determined relation between the anterior cerebral arteries and the furrows and ridges along the meson of the dorsal surface of the callosum. Whether or not the pressure of the arteries is the sole cause of the two parallel furrows and the three corresponding ridges (*Striæ longitudinales*, *Nervi Lancisii*, etc.), the arteries lie in the furrows in all the brains examined by me in which the latter are distinct. Preparations illustrating this relation were shown at the meeting above mentioned, and are referred to in the journal there cited.

Inaccuracies.—Under this head may be embraced errors which are comparatively trivial, which have no direct bearing upon larger questions of morphology or physiology, but which deserve attention, both because they go to make up descriptive anatomy and because, so long as they remain—on the principle *falsus in uno, falsus in omnibus*—distrust of other matters may be entertained.

"Centrum ovale majus."—The name is placed in quotation marks in order to indicate at the outset the fact that what is commonly understood thereby has no real existence. Not only in Quain and Gray, but in nearly every anatomical treatise published during the last hundred years, the following statements are expressed or implied, either in words or in figures, or in both: "When the dorsal portions of the cerebral hemispheres are removed by a section coinciding with the dorsal surface of the callosum, the latter forms, with the cut surface of the hemispheres, a continuous and unbroken area of alba (white or medullary substance), bordered by the convoluted cinerea (gray substance, cor-

tex) of the gyri. This area is the *centrum ovale majus*, to distinguish it from the *centrum ovale minus*—the area of alba bordered by cinerea which is seen when either hemisphere is sliced at some distance dorsad of the callosum."

The current descriptions involve two points:

1. Excepting at its ends, a line coinciding with the dorsomeson of the callosum is approximately straight, so that there is no choice as to the part which the plane of section is to reach.

2. A straight line, coinciding with the dorsomeson of the callosum, and extending laterad through both hemispheres, lies at all points dorsad of the procelia, so that the latter is not opened by the section described.

The facts are, however: 1. The dorsomesal line of the callosum is not straight, but curved throughout its whole length, so as to necessitate a choice of the parts with which the plane of section is to coincide. 2. A horizontal straight line drawn laterad from most points in the dorsomeson of the callosum will intersect the procelia, so that the latter is exposed by the section described.

So far as I know, this error was first corrected by Dalton. In the course of a description of some macroscopic sections of the brain before the New York Academy of Medicine, March 6, 1879,* Dr. Dalton stated that "the *centrum ovale* (majus) as represented in the books did not exist, and was a picture of the imagination. The reason was that the corpus callosum, instead of being a plane, was an arched commissure, and it was impossible to make sections which would show what the books illustrated."

As shown in Fig. 43 (this journal, February 23d, p. 209) and Fig. 47, representing adult brains hardened within the cranium, the callosum is not only arched, but arched both ways. The genua and splenic ends are lower than the intermediate portion, and the lateral portions are higher than the mesal. It may be compared to an inverted saddle. The relative levels and thicknesses of the mesal and lateral portions are such that the lower surface of the latter is higher than the upper surface of the former, and the two procelian cellæ are opened by a section such as is usually described.

Did space permit, and were the matter of any special intrinsic consequence, it would be interesting to consider in detail the treatment of the "*centrum ovale majus*" by different authors.† The following summary of possible explanations of the almost universal acceptance of it may also serve to account for the origin and perpetuation of some other anatomical myths:

1. It is not impossible that an exceptional brain may present the condition commonly described.
2. When the section is in a plane coinciding with the cephalic or caudal slope of the callosum, the procelia may not be opened thereby.
3. The plane of section may not be *at* but only *near* the dorsal surface of the callosum.
4. As ordinarily prepared, the brain is greatly flattened,

* As reported in the "Medical Record," April 19, 1880.

† Among the very few anatomical treatises in which it is not mentioned is that of Harrison Allen.

* Repeated observations and preparations of this fasciculus in the cat had been made by me before my attention was called to the few works and papers where it is mentioned (Izzani & Lemoigne, Gudden, Fovel, Henle, Schwalbe, and Stricker), and I had given to it the name *cimbria* (in architecture, a band or fillet about a pillar) before Gudden's name was known to me (*J. 9. 1-4*, and Wilder and Gage, 475, Pl. II, Fig. 4; Pl. III, Fig. 9, 11, "*emb.*"). As will be discussed in the latter part of this lecture, the substitution of the single brief term *cimbria* for the prior *Tractus peduncularis transversus* may be advisable, if the part in question proves to be of considerable morphological or teleological importance.

Since the foregoing went to the printer, I have received Seguin's "Gudden's Atrophy Method," etc. (*J.*), stating that the *cimbria* was first described and figured by Gall and Spurzheim, in 1810.

and the distortion may affect the relative levels of the callosum and proccelia in the way described.

FIG. 47.—OUTLINE DIAGRAM OF THE CEPHALIC ASPECT OF PART OF A TRANSECTION OF AN ADULT HUMAN BRAIN AT THE MEDIODORSAL COMMISSURE. Showing (a) the thickness of the *Commissura fornicis*; (b) that the "centrum ovale majus" would be interrupted by the proccelia; $\times 2$.

Abbreviations.—Cs. f., *commissura fornicis*; hmspt., hemiseptum (lateral half of the septum incisum); H. H., horizontal dotted line coinciding with the dorsimeson of the callosum and intersecting the proccelia cells; M. M., the meson.

The pia is seen to dip between the hemispheres. Its prolongation, the velum, may be said to line the interval between the fornix and the subjacent thalami and diatela. The endyma lines the diacelia, and forms a continuous lining for the proccelia at each side, but the proplexuses are not shown; their relations will be indicated in another figure.

The brain was hardened in the skull and the cells were uninjected, but without pressure enough to distend them unnaturally. The figure includes only the parts concerned with the *Commissura fornicis* and the centrum ovale. The only "restorations" consist in (a) representing the lateral masses of the fornix upon the same level and equidistant from the meson, instead of slightly displaced, as in the specimen; (b) introducing a curved line to represent the diatela or primitive roof of the "third ventricle," which is, in reality, complicated by the diaplexuses; (c) the omission of the proplexuses.

5. It is much easier to copy figures and paraphrase descriptions than to make original ones.

6. Writers do not always seem to compare carefully the conditions presented in their own figures.*

Commissura fornicis.—In 1861 Reichert (Figs. 34, 35, "W") represented the fornix (when transected at or near the plane of the mediodorsal commissure) as consisting of thick lateral masses conjoined across the meson by a thin lamina, to which he gave the name *Commissura corporis fornicis*, or *Commissur des Gewolbes* (pp. 70, 158, 159).

Notwithstanding the classical nature of the work just referred to, I have yet to see a recognition of the name or of the anatomical feature indicated thereby. On the contrary, with the single exception of Fig. 1 in Plate LXXXII of Har-

rison Allen's treatise, the mesal portion of the fornix,* whether in transection or in mesal hemisection, is represented as much thicker than there is reason to think it ever really is. This is particularly the case in the transections of the brain within the cranium already mentioned (Gray, Fig. 383; Quain, II, Fig. 306); the same error occurs in Henle (Fig. 82), while in "The Anatomy of the Head," especially in view of the prefatory remark (p. vi) respecting the accuracy of the drawings, the representation of the fornix is almost grotesque.

In reality, as shown in Fig. 47, in an adult human brain well hardened by alcohol, the thickness of the fornix along the meson dorsad of the diacelia is not more than 1 mm., one fourth or one fifth that of the thicker part of the lateral masses.

The error just mentioned is to be accounted for as follows: The *Commissura fornicis* is thin, delicate, far from the surface of the brain, not parietal to any true cecelia, and apparently of little or no physiological importance. Hence it is rarely reached by preservative agents, apt to be torn in removing or examining the brain, and easily overlooked in its dissection. When torn, the observer might conclude that the lateral fornical masses were normally in contact by the somewhat extensive mesal surfaces just ventrad of the commissure, and ignore the difference between the natural and artificial areas. Upon the meson of an accurately hemisected brain, of course the cut edge of the commissure should appear as a smooth, narrow area just dorsad of the wider natural surface of the lateral mass. But, as just remarked, the distinction might be overlooked, and, in fact, the plane of the hemisection is rarely accurately mesal; and, if, as often happens, the parts chanced to be slightly displaced, the plane of section might divide the thick lateral mass of one side, and only a careful inspection of the other would disclose the existence of the thin and undivided commissure.

In addition to the foregoing considerations, which are not only excuses for error, but also arguments for improved methods of manipulation, it is probable that, if the writers and students of treatises on descriptive anatomy heeded the embryological fact that the two halves of the fornix are primarily distinct, the commissure being a secondary formation (Lecture I, Figs. 36, 37, February 16th, p. 182), they would have been less apt to ascribe such thickness to the mesal portion.†

* For convenience, the word is here used in the ordinary sense to designate a single arch; the desirability of a change in this respect will be discussed farther on.

† It is proper to mention that until about a year ago I also had overlooked Reichert's application of the name *Commissura fornicis* to the thin mesal lamina, and had suggested the same name (9, 134; 14, 543; Wilder and Gage, 476) for, in the cat, a distinct band across the caudal aspect of the fornix, on which rests the crista, and which apparently unites the two columns more closely. In correcting this oversight at the meeting of the American Neurological Association (Transactions, etc., "Journal of Nervous and Mental Diseases," July, 1883, p. 85), and in proposing to substitute for the band in question the name *vinculum* (printed *vericulum* by mistake), I may have committed still another, in case the vinculum of the cat should prove to be what Reichert designates as *Commissura columnarum fornicis* (70, 161, Fig. 35, "W"). Upon this point the materials now at my command do not enable me to satisfy myself.

* A striking example of this carelessness is afforded in each of the two works already named—Quain, II, Fig. 306; Gray, Figs. 381, 383. The transections purport to represent the brain in the skull, and in each the level of the callosum is below that of the proccelia. Perhaps, however, like other prominent features of these figures, this is purely imaginary, or due to a misconception on the part of the artist; the latter supposition must also be held to account for several startling peculiarities of Plates IV and V in Dwight's "The Anatomy of the Head," where the impossibility of the existence of a "centrum majus" is linked with impossibilities of a less instructive kind.

The Complete Circumscription of the Tip of the Mediocornu by Nervous Matter.—Without discussing here a point which was referred to in Lecture I (February 16th, 181, Fig. 27), and which will be considered more fully farther on, it may be admitted that, along a line extending for most of the length of the medicornu ("cornu descendens"), the proper nervous wall is abrogated so as to constitute the *rima* (part of the so-called "great transverse fissure"), and that along this line the border of the velum constituting the proplexus finds its way into the cornu. These parts are commonly so described as to imply that the rima and the plexus extend to the *extremity* of the cornu, and that the latter therefore is in no part of its length completely surrounded by a continuous wall of nervous tissue.

In Gray (p. 638) the rima is said to extend "to the end of the descending cornu." In Quain (II, 349, 350, 351) the statements are even more explicit: The rima is said to extend "from the extremity of the descending cornu"; the choroid plexus "to the point"; and the choroid artery to enter "at the lower end." The same are expressed or implied in most works upon descriptive anatomy, and in Leuret and Gratiolet (II, 77), notwithstanding the very clear representation of a continuous, thick nervous wall by Reichert (Fig. 34).

Before this feature of Reichert's work had attracted my attention, I had, in November, 1876, ascertained that the tip of the medicornu in the cat is circumscribed for from 3 to 5 mm., and, in 1879, in an unpublished paper (4) before the American Association for the Advancement of Science,

FIG. 48.—TRANSECTION OF THE LEFT TEMPORAL LOBE OF A CHILD AT BIRTH, showing the complete circumscription of the tip of the medicornu, and the thin lamella at the end of the rima. Drawn by Mrs. Gage. A, caudal aspect; B, cephalic aspect; C, oblique view.

The plane of transection was nearly perpendicular to the long axis of the entire hemisphere, but, of course, oblique with respect to the medicornu at this place.

At A, when the page is held in a vertical plane, the transection has very nearly its natural position with regard to the meson of the entire brain. At the left and below are the lateral and ventral surfaces of the temporal lobe; this fragment was separated from the rest by an oblique incision for the sake of exposing the edge and ectal surface of the lamella *x*.

At B the transection is reversed so as to present its cephalic aspect and exhibit the thickness of the proper nervous wall.

At C the transection rests upon the cephalic surface, the caudal surface is shown foreshortened, and the lamella *x* is seen in profile to have a slightly concave free border.

demonstrated a similar circumscription in an adult human brain and in that of a child at birth (Fig. 48). Attention

has been called to the matter in subsequent publications (9, 136; 14, 541; Wilder and Gage, 487; 30, 86). In the adult brains examined, the circumscription has existed for from 10 to 17 mm. from the tip of the cornu. A like condition has prevailed in all the mammals examined by me.

The transition from a thick wall of proper nervous tissue to the rima itself, where the abrogation of this wall permits the intrusion of the proplexus, is constituted by a delicate lamella marked *x* in Fig. 48, which seems to have escaped observation hitherto. In shape it is irregularly semilunar, something like the blade of a "turf-cutter," and looks as if let into the notch between the adjoining thicker portions of the cornual parietes. Its longer and convex border is, of course, continuous therewith, but its shorter concave margin is rounded and free, excepting for the adhesion of the pia and the endyma. In substance it seems to resemble other atrophied portions of the cœlian parietes (terma, valvula, etc.). I refrain from giving a name to this lamella, partly because an appropriate single word has not yet occurred to me, and partly in expectation of learning that it has been previously observed if not named.

In general, the foregoing demonstration of a complete nervous circumscription of the tip of the medicornu illustrates the following points:

1. The possibility of omissions and inaccuracies in standard treatises.
2. The defects of the prevalent methods of preserving and examining the brain.
3. The disadvantages of purely anthropotomical methods of regarding the brain. From the condition of things in amphibia, reptiles, and birds, and in mammalian embryos, no one would take for granted, without absolute demonstration, that an interruption of the nervous parietes extended to the tip of the medicornu, or even for any considerable distance along its length.

Statements and Figures liable to cause Misconception.

—As already stated, the matters just considered are of comparatively slight importance, and merit attention mainly for the sake of attaining, so far as possible, an absolute accuracy in the description of all parts of the body.

But the points now to be discussed relate more or less directly to the question as to the extent and manner in which the encephalic cavities are inclosed, and therefore have a much wider bearing and deeper morphological significance.

With regard to two other large, hollow organs, the heart and the stomach, the continuity of the parietes is so immediately related to the performance of their principal functions that the manner of circumscription of their cavities was promptly ascertained. No such obvious or urgent physiological argument applies to the brain, but, from the purely morphological side, the aspect which should be considered in advance of both descriptive anatomy and the study of function, there is equal need to determine the extent and manner in which the encephalic cavities are circumscribed.

Judging from personal experience, from common report, and from standard and current anatomical literature, as a basis for the comprehension of the structure of the brain

nothing is more essential than a clear and correct idea of cœlian circumscription, and, at the same time, nothing is more difficult to obtain.*

The neurological expert may not need to be informed, and there are doubtless graduates in medicine who merely "follow a trade," and, like the poorer class of mechanics, hold thinking to be a waste of the time that might be spent in learning practical "rules of thumb." But among the more earnest and intelligent members of the profession there are surely many who, at some period of their course, have been haunted and almost tormented by the desire to reconcile the statements and figures in the descriptive portions of their anatomical manuals with the ideas which seem to be inculcated in the embryological divisions of the same works or in treatises upon comparative anatomy. These morphological notions constitute, as it were, principles of anatomy which are at variance with what are commonly supposed to be facts. The result is a state of intellectual unrest quite comparable with the moral disquiet which is caused by an endeavor to harmonize the "golden rule" with the habit of self-indulgence.

It would seem that some of our anatomical predecessors were badly burdened with morphological scruples. Two centuries ago Helkiah Crooke wrote as follows:

Archangelus maketh mention of a passage which is in the middle and hath a double issue, one directly into the ventricles we speak of, the other into the palate† and so into the lungs. *This passage is known to but few.* [The italics are mine.] Neither can it be found but in a sound brain when the man cometh to a sudden and unlooked-for end and is presently dissected; for the parts of the brain that are about this passage do in a short time so fall and close together that the passage is cleane obliterated.

Nor need we go so far back for misconception as to the relations of the encephalic cavities. Tiedemann (26) and Solly (173) described the "lateral ventricles" as resulting from the folding over of the hemispheres; the existence and

position of a communication between the "third" and the "fifth" ventricles are gravely discussed by Mecket (II, 450), Tiedemann, Leuret and Gratiolet (II, 8), and others; in the eighth edition of Quain (II, 543) such a communication is admitted to exist in human embryos and some animals, and it would be hard to place in a single column a greater number of perplexing misstatements than occur in Todd's account of the "ventricles" in the "Cyclopædia of Anatomy and Physiology."

In the text of the latest editions of Quain and Gray occur very few positive errors with regard to cœlian circumscription. On the contrary, on pages 346, 347, and 349 of the former, and on page 638 of the latter, there are distinct recognitions of the artificial nature of the so-called "great transverse fissure," and in general of the continuity of the lining membrane of the cavities.

The figures, however, are less satisfactory. Admitting that each figure fairly and correctly illustrates one or more points in encephalic anatomy, nevertheless, in the works above named, and even in the more elaborate treatise of Henle, besides errors and omissions in regard to other matters, every figure where the immediate cœlian parietes are represented either fails to convey any information at all, or indicates the reverse of the truth with regard to cœlian circumscription. This feature of the illustrations would be less puzzling if the extent and manner of cœlian circumscription were fully illustrated in special figures or treated of in the text otherwise than indirectly, or even if it were stated that the encephalic cavities are or are not completely inclosed, but that the figures are not designed to illustrate the matter in detail. On the contrary, in Quain, for example, one of the new figures (Fig. 291), in which is represented one of the most obscure and ill-comprehended regions of the entire brain, leaves the matter of endymal continuity and cœlian circumscription in a far more perplexing state than if it had been omitted altogether.

(To be concluded.)

Original Communications.

CASES OF WOUNDS OF THE CORNEA, IRIS, AND LENS.

By J. B. EMERSON, M. D.,

ASSISTANT SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL; LECTURER
IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

CASE I.—*Wound of the Cornea, Iris, and Lens by a Carpet-Tack; Synechia Anterior; Miscarriage; Iritis; Increased Tension; Hypopyon; Evacuation of Lens Matter and Pus by a Paracentesis; Panophthalmitis; Enucleation.*—Mrs. —, aged thirty-seven, came to my office June 19, 1883, with the following history:

On the preceding day, while shaking a strip of carpet, she was struck in the left eye by a tack. The sight in that eye was "immediately lost." Since then she had been suffering with pain, photophobia, and lachrymation. Had been using ice-water, which made her eye feel more comfortable. There was considerable difficulty in examining the eye, owing to the photophobia

* This view of the case was presented in the first lecture in the four following propositions, the first and second indicating the prevalent custom, and the third and fourth my own conviction and practice:

1. The brain is regarded as a fibro-cellular mass, penetrated here and there by inconsiderable cavities.
2. Little attention is paid to the membranes which line these cavities and invest the entire organ.
3. The arrangements of the solid parts of the brain are more readily perceived and more easily remembered after the relations of the cavities are fully understood.
4. An adequate idea of the circumscription of the cavities involves a distinct recognition of their lining and of the investment of the whole brain.

For seven years I have been in the habit of beginning the account of the brain, whether for anatomical or for physiological purposes, by a description of the cavities, their mode of origin, their succession, etc., the parietes being described as built up around them and gradually differentiated. It is quite possible that other teachers have followed the same method, but I am not aware that it was formulated or even mentioned prior to the publication of "Anatomical Technology," where it is given on page 401.

† This sounds almost like a prophecy of the comparatively recent determination of the manner of formation of the hypophysis as a diverticulum from the mouth. See Quain, ii, 831, and the papers there mentioned.

and spasm of the lid, but the following conditions were noted: The cornea was perforated with a ragged wound extending from the upper third downward and outward to a little below the pupil. The iris was wounded at the pupillary margin and adherent to the corneal wound; the pupil was contracted; no anterior chamber. The lens was completely opaque. The patient could only tell light from darkness. With the exception of slight lachrymation, the right eye was normal. Small pieces of cloths, rendered cold by having been kept on a block of ice, were advised, to be changed every few minutes, or as soon as they became warm, and the instillation of a drop of solution of sulphide of atropine (gr. iv- $\frac{3}{4}$) every three hours.

June 20th.—Less pain; pupil partially dilated; synechia anterior of the lower third of the iris; anterior chamber empty.

24th.—Patient is confined to bed by a miscarriage. The wound in the cornea is closed. The anterior chamber filled above the synechia, lens swollen, and lens matter protruding into the anterior chamber; ciliary region injected. Slight iritis. Tension of the globe about normal. Continue ice-cloths and atropine.

July 1st.—Patient was comfortable until last night, when the pain became severe, and extended through the left side of her head. Increased redness of eyeball. Advised, in addition to the previous treatment, that two leeches be applied to the left temple.

3d.—Eye feels better, but there is still considerable pain. Tension of the globe is increased. Advised two more leeches.

4th.—Eye feels much better.

6th.—Pain returned last night. Some chemosis of the conjunctiva. Small amount of pus in the anterior chamber. The cold cloths make the eye more uncomfortable. Advised that hot water be used instead, and two more leeches be applied.

7th.—The eye felt more comfortable after leeching and use of the hot water. Chemosis increased. More pus in the anterior chamber. Tension markedly increased. The protruding lens matter in the anterior chamber has assumed a peculiar yellowish color. The pus and some of the lens matter were evacuated by a paracentesis, done with an iridectomy knife, and a bandage was applied.

9th.—Patient has been more comfortable. Wound still leaking.

10th.—The wound is closed. Pain and chemosis more marked. Cornea infiltrated. Iris is suppurating. The patient has been steadily losing flesh and strength, and now is comfortable only when under the influence of morphine; as panophthalmitis is most probably setting in, enucleation is advised. Dr. Francis Valk saw the case with me, and agreed in the advice.

11th.—Eye enucleated without trouble under the influence of ether. On opening the eyeball, pus and exudation were found involving the whole of the ciliary region. The vitreous clear, except at the anterior part.

17th.—Wound healing. Patient still complains of the pain in left side of head. Advised tonics of iron and quinine.

20th.—Patient is looking much better. Says she "feels like another person." Wound healed. Advised artificial eye to be put in at once.

The right eye has given no trouble except slight lachrymation.

CASE II.—*Wound of the Cornea, Iris, and Lens by a Com-brie Needle; Chemosis; Iritis; Swelling of the Lens; Increased Tension; Lens and Thickened Capsule extracted; Secondary Hemorrhage; Atropine Poisoning; Phthisis Bulbi.*—Mrs. —, thirty-six years of age, was sent to Dr. Roosa's clinic at the Manhattan Eye and Ear Hospital, July 19, 1883, by Dr. W. A. Dayton, with the following history:

On the 30th of June the left eye was wounded by a sewing-

needle, her elbow being accidentally struck while she was holding the needle. The cornea was punctured in the upper half just above the pupil, the wound extending through the iris and lens. Was seen by Dr. Dayton a week later, who used atropine and leeches. At present has slight chemosis. Some pain; pupil well dilated. Anterior chamber nearly entirely obliterated by the swollen lens. Tension of the eye much increased. Lens opaque, and a small amount of lens matter or pus in anterior chamber. Patient can not tell light from darkness. Right eye normal, with a slight error of refraction. Patient was admitted to the hospital, and two leeches ordered on the temples and atropine continued.

July 21st.—Has had more pain. Eyeball hard. Ether was administered, and a broad iridectomy performed upward and inward, and considerable amount of lens matter spooned out. It was then found that the entire pupil was filled with a thickened and infiltrated membrane. The wound being too small to permit of its removal, it was enlarged with scissors, and the mass removed with iridectomy forceps, leaving a black pupil. Bandage applied.

August 3d.—Has had no pain since the operation. Eye steadily improving until last night, when she complained of severe pain. The eye became more injected.

4th.—More pain last night. The anterior chamber is full of blood (two weeks after the operation); atropine, hot water, and bandage ordered.

5th.—Feels comfortable; anterior chamber three fourths filled with blood.

6th.—Anterior chamber half full of blood.

10th.—Hæmorrhage entirely absorbed, leaving the pupil and coloboma blocked with an inflammatory membrane.

Patient has perception of light.

September 1st.—Eyeball has slowly cleared up.

Patient can now see objects.

October 1st.—Patient has been using atropine at home, and now has the peculiar glistening condition of the skin of the lid and cheek, showing that atropine is producing local irritation; eye-ball much shrunken; stop all treatment.

15th.—Eyeball entirely free from redness, but still shrinking.

CASE III.—*Wound of the Cornea, Iris, and Lens with a Stick; Removal of Lens Matter through the Wound; Synechia Anterior; Recovery, with a Slight Opacity of the Cornea and Synechia Anterior; Perception of Objects.*—Thomas —, three and a half years of age, was brought to Dr. Roosa's clinic at the Manhattan Eye and Ear Hospital by his mother, on August 25, 1883, who said that he had been struck in the right eye that morning with a stick. Ether was given, and the following condition observed: The cornea perforated, wound extending from outer and upper third down to the ciliary body; iris against posterior surface of cornea; lens matter extruding through wound in the capsule near the center. By pressure with the spoon, much of the lens matter was got out through the wound, when vitreous began escaping, and the remaining lens matter disappeared from view. Vitreous cut off with scissors; edges of wound coapted; atropine solution instilled and bandage applied.

August 26th.—No pain; no anterior chamber; slight ciliary injection.

27th.—Anterior chamber formed, and small amount of hæmorrhage into it. No pain.

September 1st.—Hæmorrhage nearly absorbed; some iritis.

18th.—Eye has become quiet; synechia anterior; small amount of lens capsule in pupil; opacity of cornea; patient can see objects.

CASE IV.—*Wound of the Cornea, Iris, and Lens by a Tack;*

Iritis; Synechia Posterior; Absorption of the Lens; Perfect-looking Eye; Good Vision with a Glass.—Mrs. W., aged thirty-five, came to Dr. Roosa's office, while I was in charge of his patients, July 10, 1883, with this history: On the preceding day she was taking tacks out of a chair with a dinner-knife, when one of the tacks flew up and struck her in the left eye, causing the immediate loss of sight in that eye. Since then she has had pain and photophobia, and has been using ice-water, which made the eye feel more comfortable.

The eyeball was red in the ciliary region; the cornea and iris perforated at outer third; the pupil contracted; the lens opaque; a good anterior chamber. Under the influence of atropine, which was used at the office, the pupil dilated on its inner half, leaving an unbroken synechia posterior of its outer half.

Patient can only tell light from darkness with the left eye. The vision of the right eye is $\frac{2}{3}$, and not improved with glasses.

The ophthalmoscopic examination showed a normal fundus with hypermetropic refraction. Advised to use iced cloths and a solution of atropine sulphate (gr. iv- $\frac{3}{4}$) every three hours.

July 17th.—Has had a little pain; ciliary region still red; left pupil irregularly dilated.

The lens is swollen, and lens matter protruding into the anterior chamber; tension of the eyeball normal.

Vision of right eye same as before; continue treatment.

23d.—The eye in same condition; stop iced cloths; lens matter absorbing.

August 23d.—The eye has slowly improved; the redness entirely gone; the pupil is well dilated, but irregular; small amount of lens matter in anterior chamber; no pain; continue atropine.

November 3d.—Atropine was discontinued several weeks ago; the pupil is black and nearly round; minute opacity of cornea, and just behind it a small perforation of the iris about half way between its outer and free border; small amount of lens capsule at the lower part of the pupil.

Vision of the right eye with $+\frac{1}{2}$ is $\frac{2}{3}$ +.

Vision of the left eye still $\frac{2}{3}$.

Patient can read No. 1 of Jaeger's test letters with $+\frac{1}{2}$ with the right eye, and No. 2 Jaeger with the left.

Advised a glass $+\frac{1}{2}$ for reading with left eye.

These cases are good illustrations of a class which is of interest not only to the ophthalmic surgeon, but to all practitioners, since they rank among cases of emergency. General practitioners are much more apt to see them first, and in remote districts they are called on to conduct them to their termination.

Uncomplicated punctured or incised wounds of the cornea as a rule heal with little difficulty, the indications for treatment depending entirely on the size and situation of the wound, the object being to prevent adhesion of the iris to the wounded surface. If the wound is small and situated in any part of the cornea, or large and situated near the center of the cornea, sulphate of atropine should be used; if, however, the wound is large and near the periphery of the cornea, the sulphate of eserine will contract the pupil and thus draw the edge of the iris away from the wound. A flannel bandage should be applied to the eye until the wound is closed and the anterior chamber filled.

Uncomplicated punctured or incised wounds of the cornea are rare, as the projectile is more than likely to wound both the iris and the lens, on account of their nearness to the posterior surface of the cornea. The escape of

the aqueous throwing them forward would bring them either against the projectile or into the wound, thus causing a wound or a prolapse.

Excluding entirely those cases where the ciliary region is involved, the prognosis in wounds of the cornea, iris, and lens must be very guarded, and will depend to a large extent on the size, the location, and the nature of the projectile causing the wound.

We can never be certain that the deeper parts of the eye are not involved, owing to absence of the anterior chamber, irregularity of refraction, and a "nervous" condition of the patient immediately after the accident; and subsequently (within twenty-four hours) the opaque lens prevents the possibility of examining the fundus.

The projectile is always more or less rough, and causes contusion and laceration of the edges of the wound, thus rendering union by first intention improbable. Again, the parts wounded are not only lacerated and contused, but they are liable to be irritated if not inoculated by particles of dust, iron-rust, etc., which are found on such bodies as tacks, needles, etc. Nor can we get at the parts to cleanse them, as the first principles of surgery teach.

The most favorable result will be an eye without a lens and with a scar on its cornea—an eye which without glasses will only be of use in preventing collision with large objects approaching from that side. And while there are cases where patients have used the necessary correcting or focusing lens over the *lensless* eye, and a plane glass over the other, it is the exception rather than the rule. In Case IV the patient could see better with the left eye and a glass than she could with the right; but, owing to dizziness when she attempted to walk, she was unable to use them. But, for reading, she found the left eye better than the right, and used it to the exclusion of the right, which was probably congenitally amblyopic. The termination, then, will extend from entire loss of the eyeball to the above-described condition.

The treatment must depend on the condition of the eye. Where the wound is small and there is not much reaction, the indication is to get the *pupil dilated* and combat secondary inflammation with iced cloths and leeches. If the iris is prolapsed and can not be replaced by manipulation, it should be carefully cut off with sharp scissors.

If the eyeball becomes hard and painful, the tension should be relieved by paracentesis, iridectomy, or extraction of the lens.

If suppuration or ophthalmitis sets in, the shortest and most comfortable way out of the difficulty for the patient is to enucleate the eyeball. By doing this the patient is saved weeks of suffering, and, in the future, the danger of sympathetic irritation from a sightless and atrophied globe.

It is held by some that the socket does not develop well in children after the eyeball has been removed, and that, consequently, great deformity is caused. If this is so, the last indication is less applicable for children than for adults.

THE UNIVERSITY OF EDINBURGH.—We understand that, at the approaching centenary of the university, it will confer the degree of LL. D. on Dr. Fordyce Barker, of New York, and Dr. John S. Billings, of the army.

CALCIUM SULPHIDE IN THE TREATMENT OF DIABETES MELLITUS.

BY C. M. CAULDWELL, M. D.,
VISITING PHYSICIAN TO ST. JOSEPH'S HOSPITAL.

WITHIN the past ten years so-called calcium sulphide has been recommended by several observers as a valuable drug in the treatment of diabetes mellitus. Dr. N. C. Husted, who was himself afflicted with this disease, made a complete and lasting recovery by using the drug in connection with appropriate hygienic treatment. The doctor has since employed it with satisfaction in other cases of diabetes.

Dr. Austin Flint, Sr., has prescribed the remedy, along with suitable diet, general management, etc., in several cases which progressed favorably.

Dr. C. H. Lellman gave sulphide of calcium with remarkably good effect in a single case occurring in his service at St. Francis's Hospital in 1880.

I have used the drug in only three cases. In one, it produced no effect whatever. In the others, improvement began and recovery took place during the administration of the remedy.

The following are brief histories of the cases which ended in recovery:

CASE I.—Mr. H. B., aged sixty-five, an artist. First seen on February 20, 1888. For five or six years he had suffered from severe attacks of asthma, but, until within two years, his general health was good, although financial difficulties caused much mental depression and worry. During the past eighteen months he had noticed a slow but steady increase in the amount and frequency of micturition at night. Dryness of the mouth and throat, with marked thirst, had gradually become very troublesome, and progressive loss of strength and ambition had been observed by his friends. By far the most prominent symptom, however, was his enormous appetite—as he expressed it, “he ate like a starving wolf, yet remained hungry night and day.” Sight had not notably failed. There had been no cutaneous complication, and the bowels had remained regular.

Examination showed considerable pulmonary emphysema, slight bronchitis, and marked anemia. Skin dry. Extremities cold. Saliva faintly acid. Urine pale, acid, sp. gr. 1.042, and a strong sugar reaction with Squibb's Fehling's solution. A moderately strict “diabetic diet,” daily out-of-door exercise, with iron and one quarter of a grain of calcium sulphide five times daily, were prescribed.

February 22d.—Patient passed 185 oz. of urine to-day. Sp. gr. 1.038. Sugar abundant.

23d.—Passed 200 oz. Sp. gr. 1.040. Sugar abundant.

24th.—Passed 150 oz. Sp. gr. 1.040. Sugar abundant.

25th.—Passed 168 oz. Sp. gr. 1.038. Sugar abundant.

March 1st.—Patient's general condition has improved slightly during the past week. Appetite is less ravenous, and thirst not so intense. Passed 100 oz. Sp. gr. 1.036. Sugar abundant.

7th.—A steady improvement has been noticed in the more annoying symptoms. Night before last the patient had a severe attack of asthma, presumably due to an exacerbation of his chronic bronchitis from which he is now suffering. Passed 69 oz. Sp. gr. 1.030. Sugar abundant. Ordered an expectorant mixture for bronchitis, and fluid extract of quebracho should asthma return.

14th.—Continuous improvement in the diabetic symptoms,

but there were two attacks of asthma last week. Passed 63 oz. Sp. gr. 1.034. Sugar present.

22d.—Improvement continues. Amount of urine not ascertained. Sp. gr. 1.028. Sugar present.

April 2d.—Excessive thirst and hunger, with frequent calls to micturate, have ceased to annoy. An appreciable gain in flesh and spirits has taken place within two weeks. Passed 60 oz. Sp. gr. 1.020. No sugar.

4th.—Passed 53 oz. Sp. gr. 1.026. Trace of sugar.

15th.—For the past ten days the urine has contained no sugar, the sp. gr. varying between 1.020 and 1.030. The diabetic symptoms have subsided.

October 23d.—The patient was seen to-day for the first time in five months; during that period he has had no return of his former symptoms. A specimen of his urine gave an acid reaction, sp. gr. 1.016, and contained no sugar.

CASE II.—Mr. S. D., aged twenty-four, leather dresser. Came under observation May 22, 1883. The patient had been healthy and fairly robust until about one year ago, when he began to lose flesh and strength, to have continual thirst, irregular appetite, flatulent dyspepsia, persistent constipation, repeated headache and backache, and frequent micturition accompanied by urethral smarting. There had never been chills or sweating during this period. The above symptoms continued, although much modified, for a time, by treatment. During the past four months a dry morning cough, occasionally accompanied by “stitch-like” pains in the right side of chest, with slight dyspnea on exercise, had been added to the other symptoms. The young man gave no family history of phthisis, but his business had necessitated his remaining in a dusty atmosphere for many hours each day.

Physical examination showed consolidation of the right apex anteriorly, a considerably enlarged spleen, dry skin, with patches of eczema on the lower extremities and genital organs. The mouth and throat were red and irritated, but not particularly dry. Saliva neutral in reaction. Urine clear, pale, acid, sp. gr. 1.038, strong sugar reaction with Fehling's solution. A diabetic diet, cod-liver oil, iron, and sulphide of calcium in one-half-grain doses three times daily, were ordered. Also a laxative pill and regular exercise in the open air.

May 23d.—Passed 165 oz. of urine to-day. Sp. gr. 1.040. Sugar abundant.

29th.—During the last five days the daily amount of urine passed has varied between 170 and 150 oz., the sp. gr. ranging from 1.040 to 1.035.

June 8th.—Slight improvement has taken place in his general condition. The diabetic symptoms are less annoying and the digestion markedly improved. Urine not measured. Sp. gr. 1.035. Sugar abundant.

15th.—Passed 70 oz. Sp. gr. 1.030. Sugar present. Patient is improving steadily.

21st.—Passed 72 oz. Sp. gr. 1.030. No sugar.

30th.—Urine not measured. Sp. gr. 1.025. No sugar present. Diabetic symptoms have disappeared, but evidences of the lung trouble are present to the same extent as formerly.

July 25th.—The urine has been examined frequently since the last note, and has always been free from sugar, but, as the symptoms and physical signs of lung consolidation did not improve, the patient was advised to start for Switzerland at once. He did so a week ago.

October 22d.—Nothing further has been learned concerning this patient.

It will be observed that in the first case improvement commenced in two weeks, but the sugar did not entirely disappear until six weeks after treatment was begun.

In the second case benefit was unquestionable at the end of three weeks, and no sugar was detected after one month of treatment. The patient with whom calcium failed took the drug faithfully for one month.

Although calcium sulphide is certainly not a specific in diabetes, yet it seems worthy of a trial in persistent cases of this distressing disease.

CASES OF KNEE-JOINT EXCISION, WITH REMARKS.*

By CHARLES MCBURNAY, M. D.,

SURGEON TO BELLEVUE AND ST. LUKE'S HOSPITALS.

MR. PRESIDENT: In my paper to-night I am able merely to present the histories of all my cases of knee-joint excision as a contribution to the statistics of that operation, with especial reference to the danger and mortality arising from this operation.

CASE I.—Frank Halle, aged twelve years. His parents gave a history of synovitis, complicated by abscesses occurring at the age of two. Both knees were affected. When the patient came under my observation at the Orthopedic Hospital, the right leg was flexed so as to form an angle of 25° with the thigh. No extension was possible. The left leg was flexed as much, but could be extended so as to form an angle of 90° with the thigh. The boy moved by sliding about on his toes, the heels touching the buttocks. Both knee joints were surrounded with cicatrices of old sinuses. On June 10, 1878, I attempted to excise the right knee joint, as the head of the tibia was displaced very far backward, and forced extension, aided by tenotomy, had been attempted on the left leg without success. Owing to the great displacement of the leg backward, and the shortening of the hamstring muscles and posterior ligaments, I was obliged to remove no less than four inches of bone, so that the femur was sawn, after several sections had been made, far above the epiphyseal line.

The operation was done under the constant use of the carbolic-acid spray, and a complete Lister dressing was applied. A plaster-of-Paris bandage was applied to the thigh and to the leg, the plaster appliances being connected by hoops of iron curved over the joint outside of the dressing. Horse-hair drainage was used. This case required a great deal of nursing. Numerous sinuses formed, an abscess had to be opened in the popliteal space, and necrosis of a portion of the lower end of the femur occurred. Bony union was not firm until May 6, 1883—nearly ten months after the operation. By June 2d the patient was able to walk with a support on the left side, such as a chair or crutch. It was my intention to operate upon the other knee, but permission to do so was refused by the parents.

CASE II.—Kate Lyons, aged twenty-nine. This patient came under my observation in December, 1882, at Bellevue Hospital. Ten months before this time she had had an attack of acute articular rheumatism, which especially affected the right knee joint. I found the leg flexed at a right angle with the thigh, rotated outward, displaced outward and backward, and firmly ankylosed. The patient was quite helpless from the deformity, was weak and anæmic, and her urine contained granular casts. I excised this joint on January 4, 1883.

The patella was firmly adherent to the femur, and was removed. To allow proper extension of the leg, it was necessary to make a second section of the femur.

The bones were drilled at two points and silver wires in-

serted, which were brought out between the flaps. Full Lister precautions were used throughout the operation, and a Lister dressing was applied. Rubber drainage-tubes were used. A plaster splint was applied to the thigh, and another to the leg, and these were connected by iron brackets passing over the knee.

Seventeen days after the operation I found it necessary to continue the leg splint down to the toes in order to prevent eversion. The limb confined by the plaster apparatus was kept upon an inclined plane, this position aiding in steadying the femur and also allowing the under portions of the dressing to be easily inspected.

The average temperature during the seventeen days following the operation was 100-2° F. On one occasion, seven days after the operation, symptoms of carbolic-acid poisoning appeared, and the temperature suddenly rose to 105-2°. A bichloride dressing was applied, and the temperature at once fell to 101-2°.

On no occasion was there the slightest reason for anxiety about the case, except when the symptoms of carbolic-acid poisoning were present. A collection of pus formed in the upper synovial pouch, and the silver wires also caused suppuration along their track. The patient was discharged able to walk well on April 28th, a little less than four months after operation. The shortening in this case is one inch and three quarters.

CASE III.—Charles McKenzie, aged fifteen, a healthy, well-developed boy, suffering from atrophy and deformity of the left lower extremity and left half of the pelvis, due to infantile paralysis, came under my care at St. Luke's Hospital, February 1, 1883. The thigh was partially flexed upon the body, the leg was flexed at a right angle to the thigh, rotated outward and displaced backward. No ankylosis existed, but the greatest extension possible was 112°. The muscles of the thigh, leg, and foot were completely helpless, and the whole limb looked like that of a boy ten years of age. The shortening, as ascertained by careful measurements, was estimated to be over five inches. This patient was able to move about with difficulty on crutches.

I excised the knee joint February 17, 1883. The tibia and femur were wired together with silver wire. Two rubber drainage-tubes were used, one on the inner and one on the outer side of wound, and the wound was washed with carbolic acid and water, 1 to 40, and covered with gauze wet in the same solution. Dry gauze and borated cotton were bound over this dressing. A plaster splint (such as is here shown) was then applied, a single curved iron bracket passing over the knee, and a single nearly straight one passing behind. The limb was then kept upon an inclined plane.

This patient's temperature rose on the next day to 104° F., on the second day sank to 103°, and by the sixth day stood at 99-6°. From this time on there was never any temperature above 100-6°, and that point was reached only once.

In this case also pus formed in the upper synovial pouch, and along the track of the wires.

Firm bony union was found on April 28th, two months and eleven days after operation.

By May 4th all sinuses were soundly healed, and, with an artificial shoe constructed to make up for the extreme shortening, the patient was walking about with two sticks by July 4th.

At the present date he is able to walk easily and for long distances with a single cane. I can not present this patient, as he lives in the northern part of this State. I have a very recent report of his condition from his physician.

CASE IV.—Sereno Cappa, aged twelve. Five months before coming under my care, at St. Luke's Hospital, this boy had received a kick upon the right knee, the injury being rapidly followed by arthritis, abscesses, and caries of the head of the tibia. On examination, I found numerous cicatrices about the knee, the

* Read before the New York Surgical Society, March 25, 1884.

soft parts much thickened, great pain on motion, and two open sinuses leading to carious bone in the head of the tibia. The leg was slightly flexed, and motion of four or five degrees could be made when the patient was etherized. I determined to excise the joint, as the only means of saving the leg, and to remove the carious bone at one operation. This I was able to do. The section of the femur was made just below the epiphyseal junction, and the usual section of the head of the tibia. This last section opened several small abscesses in the head of the tibia, two of which had fistulous tracts leading out through the skin. These I scraped out from the sawn surface, thus making grooves on the upper end of the tibia, in which drainage-tubes of rubber could lie, without separating the femur and tibia. The patella was removed, and silver wires were used to assist apposition. Three tubes were inserted and brought out in the line of union of the skin. Drainage-tubes were also inserted at each lower angle of the incision, to drain the superficial wound. A plaster-of-Paris apparatus was then applied similar to the one here shown, with a single bowed bracket in front and a nearly straight one behind. A peat dressing was applied. The first dressing was changed on the fifth day, and after that frequent dressings were made, and thorough irrigations with 1-to-40 solutions of carbolic acid. With the exception of the evenings of the third and fourth days, when the temperature reached 100°-6° F., it did not rise above 100° up to July 10th, six weeks after the operation. The uncovered soft parts then became swollen. I took out the wires and removed the plaster splint, substituting for it a posterior woollen one. Three days later there was a sudden rise of temperature to 104°, and erysipelatous redness appeared on the leg. This attack rapidly subsided; for two days later the temperature was 99° and did not again rise. By September 15th, three months and a half after the operation, all sinuses had closed, firm bony union had taken place, and the patient was able to use the leg freely. The shortening in this case is one inch and a half.

CASE V.—Agnes Watkins, aged six. The patient came under my care at St. Luke's Hospital, May 23, 1883, being transferred from the orthopedic department. She had been treated conservatively at the Orthopedic Dispensary and at St. Luke's for some three years without success. Numerous abscesses had formed and opened, and there was extensive osteitis and caries of the lower end of the femur on the right side. The leg was flexed and displaced backward.

May 25th.—I excised the right knee joint, the section of the femur being made well below the epiphyseal line, and the whole articular surface of the tibia being removed. The patella was not adherent, and was excised. Two wire sutures were used, the twisted ends being brought out in the line of the wound. A drainage-tube of rubber was inserted at each lower angle of the wound. A plaster apparatus, including the foot, similar to that shown, was used, excepting that, as the limb was so light and small, no anterior bracket was required. Peat dressing was applied. The dressing was changed every few days, and a 1-to-40 solution of carbolic acid used as a wash through drainage-tubes. Six weeks and a half after the operation the wires were removed, and perfect union of the bones was found to have taken place. Two months after the operation the patient was up and walking about.

The temperature in this case reached 100°-2° F. on the evening of the sixth day. On no other occasion did it go above 100° until the wires were removed. The temperature then went up to 102°, but at the end of two days was again normal.

The present shortening is less than three quarters of an inch.

CASE VI.—Matthew Carey, aged seven, came under my care at Bellevue Hospital in July, 1883, giving a history of synovitis of the right knee joint originating in a traumatism received

eighteen months ago. I found the leg flexed on the thigh at an angle of 45°, rotated outward, and the head of the tibia markedly displaced backward. I divided the hamstring tendons, and attempted to straighten the limb, but, as so often happens in such cases, the shortened posterior ligaments could not be made to yield, and the head of the tibia was still more displaced. The attempt at straightening was also followed by a partial paralysis of the muscles of front of the leg.

October 18, 1883, I excised the joint, finding almost complete destruction of cartilage without ankylosis. This operation was done with constant irrigation by a bichloride-of-mercury solution, 1 to 1,000. A deep, continuous suture of catgut was used in sewing up the capsule, and a similar one for the superficial wound. A rubber drainage was inserted at each angle of the wound, and, to provide against the accumulation of fluid in the upper synovial pouch, a short tube was passed through the skin into the upper end of this sac. The wound was dressed with iodoform, carbolized gauze, and cotton, and was put up on a posterior wire splint.

The first dressing was removed thirteen days after the operation, and tubes removed. The wound had entirely healed, except at points of entrance of tubes. During November and December a troublesome dermatitis, without constitutional disturbance, set in. This was probably due to the irritating effects of carbolized gauze.

The highest temperature reached in this case was 101° on the evening of the day after operation, and again once on the third day. The average temperature was very nearly 99°-5°. The position is good, and the boy can walk, but to-day—five months after operation—bony union is not quite perfect.

CASE VII.—George Betz, aged seven, a very strumous boy, whose right knee had been previously opened by one of my colleagues at Bellevue Hospital for the relief of an obstinate synovitis with caries of patella and fungous disease of the joint. The patella had been removed and the joint carefully scraped out. The operation had apparently been entirely successful for a time, but, under my observation, pus formed in the joint found its exit through the anterior part of the upper synovial pouch, and the probe readily detected caries of the lower end of the femur. January 31st I excised the joint, finding extensive disease of the lower end of the femur. The operation was done under the constant irrigation with 1-to-1,000 bichloride solution. Catgut was employed for ligatures and sutures. The wound was dressed with iodoform, carbolized gauze, and a complete plaster splint applied over all. This dressing was not removed till six weeks after the operation. Pus was found in considerable quantity beneath the dressing. A line of prominent granulations existed throughout most of the wound. Bony union was almost complete.

The highest temperature reached in this case was 101°-4°, on the twentieth day after operation. This was probably malarial. The average temperature throughout was below 100°. I think it was a mistake to attempt to leave this first dressing on so long. Slight over-extension, which might have been rectified at an earlier date, now exists.

CASE VIII.—Mary Finkbeiner, aged twenty-six. When eight years old, this patient received an injury to her right knee which was followed by a synovitis of ten weeks' duration. She has been able to walk with a limping gait up to six months ago, when renewed disease of the joint forced her to use crutches. When the patient came under my care at St. Luke's Hospital, in February of this year, I found a large abscess in the head of the tibia opening externally about two inches below the joint, and above, through a large opening in the articular cartilage, communicating freely with the joint. Bony crepitis on motion was marked, the joint much swollen, and the leg partially flexed.

General condition of patient very bad.

March 7th.—I excised the joint, the section of the tibia opening the large bone abscess already referred to, and the first introduction of the drill on the inner side opening another. Both of these abscesses were thoroughly scraped, and openings for drainage-tubes made into them through the anterior surface of the tibia, *about two inches below the joint.* Rubber drainage-tubes were introduced through these openings. The operation was done with constant irrigation of bichloride solution, a deep and superficial continuous suture being used in the wound. A short bone-drain was inserted at either angle of the wound. It was impossible to use wire or other means to hold the bones together, as the abscesses referred to had so weakened the head of the tibia. The wound was dressed with iodoform and gauze, and the limb bandaged to a posterior wooden splint, with foot-piece to prevent rotation of the leg. This dressing was untouched until yesterday, twenty-two days after operation, when I found the wound soundly healed without pus. I removed the wooden splint, and put up the limb in the bracket splint shown. This case, like the preceding two, is not finished, and is only presented as bearing upon the question of immediate danger from the operation. The temperature record of this case is unusually good for a patient twenty-six years old. On the evening of the day after operation the temperature reached 100.4°; with that exception the temperature has never risen above 99.4°. It is noticeable, too, that, although no wires were used in this case, it was very evident at yesterday's examination that the bones were in close apposition.

The method of operating was nearly the same in all cases, a slightly curved incision being made from the back part of one condyle, across the front of the joint below the patella, to the back part of the other condyle. The patella was removed in all the cases, even when not diseased, and also as much synovial membrane and diseased capsular tissue as possible. In only the first case was any attempt made to use a drain passing from one side of the joint to the other. Two silver wires were used to suture the bones in every case except the last. The apparatus used has varied, but in five cases I have used the plaster splint with brackets similar to the one shown. This apparatus can be readily made and applied by the operator immediately after the operation, and allows of moving and dressing the limb very readily. I think that the best method is the one I adopted in the last case—that of putting the limb, immediately after the operation, in a permanent dressing and fastening it to a posterior wooden splint with a foot-piece. This provides against the chance of having to remove the plaster apparatus soon after the operation, in case of swelling of the parts or on account of accidental soiling of the plaster. At the end of two or three weeks the plaster splint with bracket can then be applied, and any desirable change in the position of the leg made. I have never tried the incision recommended by Hahn, of Berlin, which passes across the joint *above* the patella. It would doubtless allow of a more ready removal of the upper synovial pouch.

Such a removal is, I think, of considerable importance, as in most cases which I have seen there has been a tendency to the accumulation of fluid at that point. With regard to suturing the bones with wire, or nailing them together, as Hahn did in so many of his cases, I am inclined to think that neither procedure has any great value. In any

ordinary resection of the knee the posterior ligament is uninjured and forms a strong posterior support, and the natural shortening of the hamstring muscles must draw the tibia upward. Rotation seems to be the movement most to be feared, and that can be avoided by the retaining apparatus.

THE IRONDALE SPRING WATER.

By SAMUEL SWIFT, M.D.,

YONKERS, N. Y.

ABOUT two years ago Dr. W. R. Upham, of Yonkers, N. Y., spoke to me of the great benefit he thought he had obtained by the use of the Irondale Spring water in a number of cases, chiefly those of an inflammatory character (both acute and chronic) affecting the kidneys and urinary apparatus. He said he should continue his investigations, and, if in future he secured as favorable results, prepare a paper for publication. His unfortunate death occurring soon after, at the beginning of what promised to be a most successful professional career, terminated all his scientific work, and my conversation with him was for a time forgotten. In August, 1883, I accidentally heard of the remarkable recovery from chronic dyspepsia of a prominent officer in the U. S. Navy ascribed to the use of the Irondale Spring water. I remembered my conversation with Dr. Upham, and my interest in the subject was once more excited. I requested Mr. Felix Nemegyei, the owner of the property upon which the spring exists, to put at my disposal all facts in his possession relating to the discovery and use of the water. His statement to me was practically as follows:

"During 1881 this spring was discovered at Irondale, W. Va. The temperature of the water was found to be constant at about 45° F. above zero, independent of the temperature of the surrounding air, which varies from 20° F. below to 90° F. above zero. To the taste it was slightly acid. The constant coolness of the water induced its general use, but the drinking of it soon had to be discontinued. While on a few its frequent use appeared to exert a beneficial effect, most experienced unpleasant results. Its ordinary use was soon discontinued, as it also proved unfit for cooking purposes. In 1881 a gentleman in Grafton, suffering from chronic diarrhœa, unable to obtain at once the alum waters of Virginia, commenced its use as a temporary expedient. The result was surprisingly beneficial, and in about one month a complete cure was effected. At his recommendation, a lady in Morgantown, a victim of ulceration of the intestines, resulting from a serious attack of typhoid fever, gave it a trial. Her physicians had given her friends little hope of her recovery. She steadily improved, and in five weeks was restored to her usual health. A gentleman living in Clarksburg, W. Va., suffering from chronic dyspepsia, hearing of the spring, sent for the water, and soon reported himself relieved from his troubles. In the meanwhile, laborers, coming from the malarious regions of Ohio to work at the Irondale furnaces—all being more or less debilitated and anæmic—began to drink the water, and were generally greatly benefited. These favorable results were soon the talk of the neighborhood, and the farmers of the region commenced to use it in a variety of diseases. Whenever

used for indigestion, general debility (resulting from whatever cause), and gastric or intestinal disturbances, its use was found always to be beneficial, and in many cases complete cures were effected." At this time the rapidly increasing demand for the water attracted the attention of Mr. Nemegeyi. He began to use the water in his own family, and suggested its use to his personal friends. An analysis was made by Professor A. A. Breneman, formerly of Cornell University.

He made the following report:

ANALYSIS OF IRONDALE SPRING WATER IN GRAINS PER GALLON.

Chloride of sodium	1.361
Sulphate of potassium.....	6.764
Sulphate of calcium.....	60.417
Sulphate of magnesium.....	4.336
Sulphate of aluminum.....	11.337
Sulphate of manganese.....	2.857
Silicic acid.....	1.445
Vegetable and volatile substances.....	8.239
Traces of sulphate of iron, cobalt, and free nitric acid.	

It was found that the water could be transported only in glass. Wood was at once attacked, the water becoming yellow and filled with a flaky substance. Mr. Nemegeyi also informed me that the late Dr. Noble Young and Dr. McWilliams, of Washington, D. C., and Dr. F. H. Rankin, of Newport, R. I., had used the water in their practice and obtained very favorable results.

Making all allowances for the probable many cases of its unsuccessful use which have not been brought to the notice of its advocates, I still deemed the information obtained sufficient to justify me in beginning to use the water in my general practice, and requested Mr. Nemegeyi to have sent to a druggist in Yonkers a supply sufficient for a fair trial of its properties. My success has been such that I desire by this article to draw the attention of the profession to what I deem to be a valuable addition to the list of medicinal waters. I have used the water freely, and with steadily increasing confidence in its beneficial action. In no instance have injurious effects followed its exhibition; usually favorable results have been obtained, and frequently remarkable improvement and restoration to health have been secured. In simple anæmia, chlorosis, anorexia, and the various forms of dyspepsia resulting from these conditions, I now speak confidently to my patients of the favorable results that can be surely expected to follow its systematic use. The water in my hands has proved itself to be a powerful tonic. Where a tonic effect is desired I direct a claretglassful to be taken after each meal. In larger doses its diuretic effect is as well marked. In one case of diffuse nephritis, when the amount of urine passed daily had for some time varied from twenty to thirty ounces, a tumblerful of the water four times daily in four days increased the amount to fifty ounces per diem. I then decreased the dose one half, and for several weeks maintained a constant urinary secretion of from thirty-six to forty ounces, to the great comfort and relief from unpleasant symptoms to the patient during his life.

In small doses (from two to three drachms), every one or two hours, obstinate vomiting and inability to retain anything on the stomach have been overcome, and power to retain and

digest nourishment has quickly been regained. In one instance, the patient being already forty-eight hours fed by enema, all other remedies being without avail, I used this water as a last resort, with complete success; nausea ceased, and soon nourishment could be taken in the usual manner.

In fact, in no one class of diseases do I make use of this remedy, but depend upon it to treat symptoms that may occur in the course of any of them, and which my experience for the past six months has taught me may be successfully overcome or greatly alleviated by its exhibition.

In the vomiting of pregnancy it has proved of great benefit; small doses frequently repeated have in one case completely cured the morning sickness, and in two others given great relief.

As a summary of my experiments in the use of Irondale Spring water, I find that—

1. In claretglassful to half-a-tumblerful doses after eating it is a powerful and reliable tonic and antidyseptic.
2. In large doses—from one to two tumblerfuls four times daily—it acts as a free diuretic.

3. In doses of a tablespoonful every one or two hours, or sometimes oftener, it is a valuable aid in overcoming gastric and intestinal disorders—allaying nausea and promoting digestion.

4. It has proved more successful during the last six months than any other remedy at my command in the treatment of the ordinary varieties of indigestion.

5. It is not unpleasant to the taste, and has no disagreeable after-effects.

6. This is of great advantage in the treatment of children; they take Irondale as readily as the drinking water they fancy it to be.

I can only attribute the wide range of usefulness of this water to its decidedly beneficial effect on the stomach and digestive organs, strengthening the system to withstand the ravages of disease.

In anæmia, chlorosis, and kindred diseases where I used this water I found I could dispense with the use of iron preparations. Digestion was so much improved that the iron required to enrich the blood was taken from the food, the needful manganese being supplied by the water in such doses as seemed to me most appropriate.

In our usual practice, when through faulty assimilation of the food the iron and manganese have not been absorbed in sufficient quantities, we usually try to supply the deficiency by the use of iron and beef preparations, but results in many cases disappoint our expectations, and naturally so, because the digestive organs, being unable to assimilate these necessary substances from the usual food, are less able to do so when a heavier strain is put on them by an artificial increase of the same.

Professor Bartholow and others recommend the use of the preparations of manganese in all cases where I have found Irondale Spring water can be most successfully employed. I firmly believe that in the laboratory of Nature a combination has been effected, forming a natural spring water, that, judiciously and scientifically used, is capable of producing valuable therapeutical results and gaining a place among the remedial agents of the progressive physician.

NEW YORK, SATURDAY, APRIL 5, 1884.

THE PHARMACEUTICS OF ACONITE.

At a time when every adverse criticism that it is possible to bring against the new United States Pharmacopœia is likely to be brought forward in the interest of the scheme now before Congress for establishing a pharmacopœia endowed with the authority of the Government, it may not be amiss to call attention to one of the excellences of the book under which we are now working. We refer to its treatment of the preparations of aconite, and we take all the more pleasure in commending that treatment now for the reason that we criticised it mildly soon after the work appeared. We then said that, in our opinion, an error had been committed in not specifying some preparation of aconitine as the official aconite. That criticism was made, however, in the interest of experimental therapeutics, and not as at all touching the policy of the pharmacopœia from the point of view of public safety. We still feel, of course, that it would be a good thing to have a standard preparation of aconitine, and we are quite willing to concede that the framers of the pharmacopœia thought so too, but refrained from establishing one on account of the unsatisfactory state of the processes then and now in use for isolating the alkaloid. But, be this as it may, there can be no doubt felt that our pharmacopœia dealt more judiciously with the question than the new French Codex has done, if we may judge from a discussion that lately took place in the Paris *Société de Thérapeutique*, a report of which we find in a recent issue of the "*Gazette hebdomadaire de médecine et de chirurgie*."

It seems that the new codex recognizes no other aconitine than the crystallized form, whereas the codex it supersedes admitted the amorphous alkaloid. As the former is much the more energetic poison of the two, there is grave danger that physicians' prescriptions calling simply for "aconitine," and coming from men who have been in the habit of using the amorphous form, will be filled by pharmacists in blind obedience to the established codex, and that serious misadventures in the way of poisoning are likely to take place in consequence. Although we are far from maintaining, or even supposing, that governmental authorization of a pharmacopœia would be generally construed as altogether setting aside the discretionary power on the part of dispensers which, exercised as it is by an intelligent and conscientious body of men, has come to be one of the safeguards on which prescribers feel that they must rely to some extent; yet the nationalization of our pharmacopœia would necessarily have some tendency to dull that sense of personal responsibility that lies at the foundation of the discretionary power in question, and that tendency seems to us an additional argument against the expediency of the bill now before Congress.

But it is not alone in the matter of aconitine that the codex shows to disadvantage; it admits preparations both of the leaves and of the root of the aconite plant. The United States Pharmacopœia of 1880 made a distinct advance in dropping the leaves from the list of drugs, for their retention would have been liable to lead at any time to errors the same in kind, if not of so serious a degree, as those that are to be feared from confounding the amorphous with the crystalline forms of aconitine. To be sure, our pharmacopœia defines aconite no more strictly than as the tuberous root of *Aconitum napellus*, without specifying in what locality it should be gathered or at what time with reference to its period of flowering, both of which factors exert a considerable influence in determining the activity of the drug; but such directions are hardly practicable, as was pointed out by one of the speakers at the meeting to which reference has been made, since it is out of the question to compel every pharmacist to gather his own aconite. These facts, indeed, are to be taken as enforcing the lesson of the caution it is necessary to observe in the use of so potent and at the same time so variable a drug as aconite.

THE TRICENTENARY OF THE UNIVERSITY OF EDINBURGH

As is announced elsewhere in this issue of the journal, the current month is to witness ceremonies in the old city of Edinburgh commemorative of no less an event than the founding of the university. Although at the time when the university was founded, three hundred years ago, America was a wilderness, perhaps it is due to this very fact, coupled with the reflection that at that time the homes of all our ancestors were on the other side of the Atlantic, that we Americans feel such a keen interest in what is going on among our European brethren, even under ordinary circumstances. But the occasion in question can not be called ordinary, in so far as the medical profession of this country is concerned, for the unusual occurrence is to take place of the conferring of honors by a European institution of learning on members of the American medical profession.

We may use the word unusual without at all losing sight of the decorations of Sims and Sayre, or of the graceful compliment paid to American medicine by the Universities of Oxford and Cambridge when they conferred the degrees of doctor of civil law and doctor of laws on the venerable Professor Gross. Unless we are mistaken, however, this will be the first instance in which the University of Edinburgh has given an honorary degree to a representative of the American medical profession. Assuredly, there can be but one sentiment felt as to the fitness of the choice it has made of the men, Professor Fordyce Barker, of New York, and Dr. John S. Billings, of the army. In distinguished and honorable careers both these gentlemen have fairly won the dignity shortly to be conferred upon them, and, while we all feel it as a welcome recognition of our profession in America, we can not allow the modesty of Dr. Barker and Dr. Billings to impute it wholly to any such general sentiment—it is due not alone to their representative character, but in great measure also to their individual qualities.

It is not altogether, or even chiefly, Professor Barker the obstetrician, however highly they may esteem his teachings

and his attainments in this particular branch of medicine, but Fordyce Barker the man, that our Edinburgh friends have long since taken to their hearts, and are now only about to clothe with the formal token of the fact. And so it is with Dr. Billings—abroad, as well as at home, he is known as something more than the bibliographer, great as his achievements are acknowledged to be in that capacity; it is partly as a sanitarian, but above all as a man of broad conceptions of the scope of medicine, endowed with the wit and the kindness to make those conceptions felt forcibly and accepted willingly, that he is esteemed. Both these gentlemen are now on their way to Edinburgh, and we are sure that in their pilgrimage they carry with them something more than the admiration of their fellows left behind, rather their affection.

THE COUNTY SOCIETY'S "COLLECTIVE INVESTIGATION."

CONSIDERABLE interest ought to be felt in the adjourned meeting of the Medical Society of the County of New York, to be held next Monday evening, for the special order of business is the report of the committee in charge of the society's first "collective investigation of disease." The chairman of the committee stated at the regular meeting that about fifty cases of the affection that is the subject of the inquiry—intestinal obstruction—had been reported, in response to the circulars sent out, all of which, he added, were "very interesting" and would be "worth listening to." This guarded statement can not be said to shadow forth a very flattering prospect, and we may be allowed to express the hope that the session will not be given up to the mere reading of fifty or more clinical histories. What the society has a right to expect of the committee, we imagine, is a critical digest of the material it has succeeded in getting together—what our French brethren would call an *appréciation*.

Taking as the phrase "collective investigation of disease" has shown itself to be, the process seems to us to be one that may very readily degenerate into a mere assembling of undigested facts, on the one hand, or a slight variation of ordinary statistics, on the other, neither of which games we are inclined to regard as "worth the candle." However, much may be excused on the occasion in question, for the subject chosen is one upon which it must be difficult for most of the members to speak positively from personal knowledge. If, then, the committee succeeds in giving more definite shape to our ideas of intestinal obstruction, it will be entitled to a great deal of credit.

THE PROPOSED INCORPORATION OF THE COLLEGE OF MIDWIFERY.

IN connection with the minority report of its committee, adopted by the Medical Society of the County of New York at its last meeting, the full text of which we give on another page, some mention seems to be called for of a bill that has been pending for some time before the Legislature for incorporating the College of Midwifery in the City of New York. At the time

this institution was established we took occasion to commend its purpose; but since then, as our readers are aware, it has laid itself open to condemnation at the hands of the profession for having issued a remarkable pamphlet entitled "Woman's Work in the Field of Medicine." Apart from the bad taste that characterized the pamphlet, it tended to give the impression that the institution had the right to confer the degree of "graduate in midwifery," and, by implication, that it was the only institution in the State which possessed this right.

This bill, now passed by both houses of the Legislature, and on the eve of becoming a law, is as bad a bill as could well be imagined, as it provides no guarantee of the quality of instruction to be given, or that improperly fitted persons will not be turned out as midwives. We understand that the attention of the Committee on Legislation of the Medical Society of the State of New York has been called to this measure; but, so far as we are aware, no effort has been made by the committee to prevent its becoming law. Unless the committee is careless of the interests of the profession throughout the State to an extent that we are not prepared to believe, we can not understand its failure to interfere in the matter.

TWO NEW CARDIAC POISONS.

WOORARI seems in danger of being outdone as a cardiac poison, if we may judge from the accounts lately given before the Paris *Société de Biologie* of two new oriental arrow-poisons. A specimen of one of these poisons was presented by M. Boche-fontaine, as we learn from a report of the meeting published in the "*Progrès médical*." It was said of this poison that an animal of medium size, wounded with an arrow the point of which had been imbued with it, would make one bound, and then fall dead; and that even an elephant would succumb after running no more than a kilomètre. The composition of the poison is not known, being kept a dead secret by the Moïs, from whom it was only by subterfuge that the specimen shown at the meeting was obtained. Taken into the stomach, the substance is said to be innocuous. One milligramme, injected under the skin of a frog, produced death within ten minutes, the heart being arrested in systole, and the reflexes persisting for a time. One of the speakers gave it as his opinion that the poison was probably obtained from the *Upas antiar*.

The other substance, shown by M. Laborde, was termed elephant poison (*poison d'éléphant*), and came from Borneo, where the inhabitants employ it for poisoning their arrows. Experiments on dogs have shown that this substance also kills by arresting the heart's action, but whether in systole or in diastole we are not told.

Two new poisons, then, are before the profession for investigation, and this will have to be directed both to their constitution and to their physiological actions. But it must be confessed that the prospect of any notable advantage accruing to therapeutics from such research is remote, while the difficulty of obtaining the substance first mentioned stands in the way of the extended series of experiments necessary before precise conclusions can be arrived at.

NEWS ITEMS, ETC.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 1, 1884:

DISEASES.	Week ending Mar. 25.		Week ending April 1.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus.....	3	2	8	5
Typhoid Fever.....	6	0	5	3
Scarlet Fever.....	83	15	96	12
Cerebro-spinal meningitis.....	9	8	6	5
Measles.....	72	9	68	9
Diphtheria.....	21	15	42	16

TRICHINIASIS IN PENNSYLVANIA.—A newspaper report from Pittsburgh states that trichiniasis caused a death in Westmoreland County last week, and that six persons were dangerously sick with the same affection.

WHOOPING-COUGH HOSPITALS.—The "Medical Times," of London, calls attention to the excessive mortality from whooping-cough in that city for a number of weeks past, and advocates the establishment of half a dozen small hospitals for children affected with the disease, where they can "be rigidly kept in a temperature like that of a southern health resort."

THE NEW SURGEON-GENERAL OF THE NAVY.—The Senate has confirmed the appointment of Medical Director Francis M. Gunnell as Surgeon-General and Chief of the Bureau of Medicine and Surgery of the navy.

THE SOCIETY OF MEDICAL JURISPRUDENCE AND STATE MEDICINE.—At the next meeting, to be held Thursday evening, the 10th inst., at the Hall of the Academy of Medicine, No. 12 West Thirty-first Street, Dr. J. Henry Fruittight will read a paper entitled "The Status of the Midwife, Legal and Professional."

THE MEDICO-LEGAL SOCIETY will hold its next regular meeting Wednesday evening, the 9th inst., at No. 64 Madison Avenue. Dr. C. H. Hughes, of St. Louis, will read a paper on "Moral (Affective) Insanity," and another will be read by Dr. J. G. Johnson, of Brooklyn, on "Poisoning by Canned Fruits and Meats."

THE TENNESSEE STATE MEDICAL SOCIETY will hold its fifty-first annual meeting at Chattanooga, on Tuesday, the 8th inst.

THE MEDICAL SOCIETY OF THE STATE OF WEST VIRGINIA will hold its seventeenth annual meeting at Clarksburg, beginning on Wednesday, May 21st. The secretary, Dr. S. L. Jepson, of No. 81 Twelfth Street, Wheeling, asks that gentlemen who intend to read papers at the meeting send him the titles of their papers as early as possible.

THE UNIVERSITY OF CAMBRIDGE, according to the "Medical Times," of London, will shortly elect a professor of pathology and four medical and surgical lecturers, one of them to take the subject of midwifery. The "Lancet" learns that Dr. Joseph Coats, of Glasgow, is a candidate for the position first mentioned.

THE JEFFERSON MEDICAL COLLEGE, OF PHILADELPHIA, held its fifty-ninth annual commencement on Friday of last week, graduating a class of two hundred and fifteen gentlemen. The valedictory address was given by Professor John H. Brinton.

THE HARVARD MEDICAL SCHOOL.—The "Evening Post" says: "Three students of the Harvard Medical School who last week passed their examinations are not happy. One wrote an excellent set of papers, the other two [sic] copied them word for word, and the examiner ranked them at 98 per cent. He

remarked, however, that, as the three papers were identical, this gave the three but about 33 per cent. each, and, as 50 per cent. is required for a diploma, all three were plucked."

THE STATE LEGISLATURE.—Bills have been reported incorporating the New York Cancer Hospital, incorporating the Good Samaritan Dispensary in New York, and legalizing all degrees and diplomas granted by the United States Medical College. The bills to make the Health Officer of the Port of New York a salaried officer and to enable testators to prove their wills during their lifetime have been reported adversely.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 23, 1884, to March 29, 1884:*

HAMMOND, JOHN F., Colonel and Surgeon, now in New York city on sick leave of absence, will, after the expiration of his sick leave, await orders in that city. Par. 8, S. O. 70, A. G. O., March 26, 1884.

GANDY, CHARLES M., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Brady, Mich., as Post Surgeon. Par. 6, S. O. 56, Headquarters Department of the East, March 22, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending March 29, 1884:*

GREEN, E. H., Passed Assistant Surgeon. Ordered to the Greely Relief Steamer Thetis.

MAESTLER, E. H., Passed Assistant Surgeon. Ordered to the Receiving Ship Colorado, New York.

BRYAN, I. H., Passed Assistant Surgeon. Resigned, to take effect April 10, 1885, with leave of absence till that time, and permission to leave the United States.

RUSH, C. W., Passed Assistant Surgeon. Ordered to the Naval Academy.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, April 7th:* New York Academy of Sciences (Section in Biology); Medical Society of the County of New York (adjourned meeting.—Discussion on Intestinal Obstruction); Medico-Chirurgical Society of German Physicians; Brooklyn Anatomical and Surgical Society (private); Utica, N. Y., Medical Library Association.

Tuesday, April 8th: New York Surgical Society; New York Medical Union (private); Jersey City Pathological Society; Newark, N. J., Medical Association; Trenton, N. J., Medical Association; Medical Societies of the Counties of Jefferson, Oneida, Ontario, Rensselaer, Tioga, Ulster, and Wayne, N. Y., Bergen (annual) and Cumberland (annual), N. J., and Fairfield, Conn.

Wednesday, April 9th: New York Pathological Society; American Microscopical Society of the City of New York; Medical Society of the County of Cayuga, N. Y.; Tri-States Medical Association (New York, Pennsylvania, and New Jersey—Port Jervis, N. Y.); New York Medico-Legal Society.

Thursday, April 10th: New York Laryngological Society (private); Society of Medical Jurisprudence and State Medicine; Harlem Medical Association (private); Brooklyn Pathological Society; Medical Society of the County of New London, Conn. (annual).

Friday, April 11th: Yorkville Medical Association (private); Medical Society of the Town of Saugerties, N. Y.

Saturday, April 12th: New York Medical and Surgical Society (private).

OBITUARY NOTES.

DR. J. HALL DAVIS, OF LONDON.—Our London exchanges announce the death of Dr. Davis as having taken place on the 19th

ult., rather suddenly, although for sometime he had been in failing health. For a number of years he had held the appointment of obstetric physician to the Middlesex Hospital, a position which he did not resign until within a week of his death. He was at one time the president of the Obstetrical Society, of which he was an honorary member at the time of his decease. Dr. Davis was favorably known in this country by various contributions to periodical literature.

DR. JAMES KENNEDY.—Dr. Kennedy died last Saturday, at the age of eighty-four years. He was a Scotsman by birth, but had lived in this country since 1827. He was a licentiate of the Medical Society of the State of New York, and had received the honorary degree of M. D. from the medical college at Castleton, Vt. He was a member of the Medical Society of the County of New York, of the Academy of Medicine, and of the Society for the Relief of the Widows and Orphans of Medical Men, and for many years had been a surgeon to the Police Department.

DR. JONATHAN A. WHITE, OF BROOKLYN.—Dr. White died last Sunday, in Macon, Ga., in his fifty-fourth year. He was a native of Massachusetts and a graduate of the medical department of the University of Vermont. He was a member of the Medical Society of the County of Kings and of the New York Physicians' Mutual Aid Association.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

Meeting of March 25, 1884.

CHARLES MCBURNEY, M. D., Vice-President, in the chair.

LARGE TUMOR OF THE THIGH.—Dr. JAMES L. LITTLE presented a man, forty-eight years of age, whose horse had reared and fallen upon him while he was in the army, twenty years ago, the pommel of the saddle inflicting a contusion on the inner aspect and about the middle part of the left thigh. An inflammatory swelling followed which lasted from the 23d of June until winter, and then disappeared entirely. Five years afterward a swelling occurred up and down the thigh, along the site of the original injury, which gradually increased until it reached its present size. The circumference of the right thigh was now nineteen inches; that of the left thigh, around the tumor, was thirty-one inches and a half. The swelling was painless and movable, and Dr. Little regarded it as a lipoma, and also thought it was a proper case for operation.

Dr. A. G. GERSTER inquired whether the tumor had been punctured, and the patient replied that only small needles had been introduced, but the aspirator had not been used. Dr. Gerster recalled a case of a tumor of this kind, situated in the same locality, that came under his observation at Mt. Sinai Hospital four years ago, in which the diagnosis of cyst was made after puncture, but in which the swelling finally proved to be an old abscess. It seemed to him that the tumor in Dr. Little's case was pretty well outlined by the entire extent of the adductor muscles. He was unable to find any lobulation, such as usually existed in lipoma, and he believed that, in order to make the diagnosis clear, it would be very important to make a puncture. The contents of the tumor to which he had referred contained an enormous quantity of cholesterol crystals. It had occupied five years in developing, its growth was very gradual,

and there was an early history of very severe pain in the thigh. Excision of the tumor was attempted, but, when he reached what was supposed to be the capsule, it was found to be simply a pyrogenic membrane closely attached to the inner surface of the adductor muscles. A very large quantity of peculiar shining liquid was evacuated, which contained cholesterol crystals and detritus. Specimens of the fluid removed by puncture prior to the operation were submitted to two microscopists, one of whom diagnosticated undoubted ovarian tumor. After having evacuated the contents, he found floating in the cavity a small solid body, which proved to be a portion of the cortical substance of the femur, from the vicinity of the small trochanter, and examination of that locality revealed a slight depression. He concluded that a cortical necrosis with myelitis had taken place five or six years before, that a sequestrum was released and became the point around which an abscess formed, that the original site of the osteo-myelitis had healed, and that the old abscess continued to exist with its pyrogenic membrane, gradually increasing to the size of the apparent growth. The man recovered entirely.

Dr. LITTLE said that, in February last, he operated on a tumor of the thigh similar to the one just described by Dr. Gerster, which was very large, and which moved with every movement of the muscles. On tapping, a shining yellow fluid was removed, which was filled with cholesterol crystals. The sac was laid open and the inner surface of the cyst was found to be covered with granulating material, which was scraped off, and the case did well. It was supposed to be the result of an old abscess. Antiseptic precautions were used.

Dr. T. M. MARKOE said that, from the feel of the growth, he should doubt whether it was a cystic tumor. He found that it was beneath the fascia lata, and that it was continuous with the adductor tendons below, which passed to the inner side of the tumor and formed a part of its internal surface. That fact alone would induce him to doubt whether it was a fatty tumor. Another feature which led him to doubt its being a fatty tumor was the fact that no corrugation of the surface was seen when it was pressed together, a feature almost characteristic of lipomatous growths. He was inclined to regard it as a form of sarcoma.

Dr. GERSTER thought that the length of time which the tumor had existed spoke against its sarcomatous character, and remarked that there was also a notable absence of any systematic disturbance.

Dr. LITTLE remarked that he had removed one fatty tumor much larger than this one, situated in the same locality.

Dr. C. K. BRIDDON said that, some ten or fifteen years ago, he saw a tumor like this in the gluteal region, which was influenced by some of the muscles arising from the pelvis and inserted into the femur. In that case he used the aspirator, as he thought, for the first time it was used for this purpose in this city, and the results were negative. Supposing it to be a fatty tumor, he made a long incision for its removal, but it turned out to be abscess with a very thick covering, which prevented fluctuation from being detected.

Dr. MARKOE said a form of tumor had been described by Paget as fibro-cellular, the histological type of which was loose areolar cellular tissue, infiltrated with serum, etc., which might attain an enormous size, and yet possess none of the elements of malignancy. He thought the tumor in Dr. Little's case corresponded more nearly to that form of growth than to any other.

OCCLUSION OF THE NOSTRIL FROM DEVIATION OF THE SEPTUM.—Dr. ALFRED C. POST presented a patient upon whom he had operated two weeks ago the preceding Friday for occlusion of the right nasal cavity from deviation of the septum. There was at the same time a periostosis of the nasal process of the

superior maxillary bone. He separated the side of the nose from the cheek and turned it over, in order to get access to the obstruction, and then removed the protruding part of the septum and some of the superfluous superior maxillary bone. The nose was then turned back and secured, and the traces of the incision would not be sufficient to attract the attention of casual observers. The occluded nostril was now quite free. It was probably a congenital deviation.

The VICE-PRESIDENT remarked that such deviation usually occurred toward the other side.

Dr. HENRY B. SANDS had performed the same operation, and found that it was very much facilitated by the separation of the ala nasi. He did not open the septum, but removed the projecting cartilaginous swelling and some bony growth situated along the floor of the nostril, and the patient recovered without deformity.

Dr. Post said he had, in several cases, divided the columna nasi, where the deviation did not extend so high up, which facilitated the operation very much, and on closing the columna no deformity remained.

DOUBLE RUPTURE OF THE TENDON OF THE QUADRICEPS FEMORIS.—Dr. MARKOE presented, in behalf of Dr. ROBERT F. WEIR, a patient, seventy-two years of age, who had ruptured the quadriceps tendon of each patella. There was the usual depression immediately above the upper margin of the patella, abrupt on both sides. The accident was caused by slipping upon a piece of ice, one knee giving way and the other tendon rupturing almost immediately afterward. There was not only the depression immediately above the patella, but also the sharp edge on either side, indicating where the aponeurosis had not been ruptured. There were, therefore, two strong fibrous bands left which enabled him to make some extension of the leg at the time of the injury. A good deal of extravasation of blood occurred about the parts. The patient was treated by placing the limb in a straight position. A large amount of effusion took place into one knee joint, but in the other not very much inflammatory reaction showed itself. The injury occurred three months ago, and the patient was now able to walk slowly. Both tendons had united equally well.

FRACTURE OF THE HUMERUS AND SCAPULA, COMPLICATED WITH SEVERE INJURY OF THE ENTIRE BRACHIAL PLEXUS, FOLLOWED BY PARALYSIS.—Dr. GERSTER presented a boy, eight years of age, who was run over by a wagon December 10, 1883. The exact mode of injury was unknown. It was alleged that immediately after the injury he could clinch his fist. He saw the patient for the first time ten days after the injury, and found an anæmic boy, with the pectoralis and serratus region widely suffused and discolored. The arm-pit was filled by a hard mass (coagulum), which caused a curious bulging of the right pectoral region. Fracture of the upper third of the shaft of the humerus was easily made out, but a lengthening of the arm, with a wide displacement of the head of the humerus from the acromion, accompanied by local crepitus, and also the fact that this deformity could be easily reduced but immediately reappeared, made the diagnosis of fracture of the neck of the scapula clear. There was absence of both brachial and radial pulse, also paleness of the extremity, with no œdema, but absolute motor and sensory paralysis of all the branches of the brachial plexus. The fracture of the humerus was dressed with three pasteboard splints, but the fracture of the neck of the scapula presented no easy problem. Finally it was found that the fragments could be best retained in position by raising the splinted arm by the bend of the elbow on a series of turns of a bandage wrapped over the shoulder of the same side, fastening all these turns by a series of turns passed around the thorax and by a loop of bandage passed around the neck over to the other axilla. At the end of

three weeks there was consolidation, with slight deformity of the humerus. The deformity was due to the necessity of lifting the shoulder by the elbow. The fracture of the neck of the scapula still showed crepitus, and therefore the bandage was continued. A pressure-sore developed over the olecranon. The deltoid, the triceps, and the biceps showed no faradaic irritability on January 15th. The sensibility of the skin showed a marked variation—one day it extended down to the upper part of the forearm, to disappear three or four days after up to the middle of the arm. The first nerve to show constant improvement was the musculo-cutaneous; the most tardy was the musculo-spiral. From the tenth day after the injury neuralgic pains were felt by the patient which were directly located in the palm of the hand. Pressure in the deep portion of the axilla caused intense pain up to the eighth week, when most of the large blood-clot had been absorbed. At the same time choreic, jerky contractions of both shoulders and the head began to be developed, which very soon yielded to the administration of Fowler's solution, continued for about six weeks.

In spite of frequent readjustment of the bandages, and much care, it was very difficult to retain the outer fragment of the scapula exactly in a correct position. This, and the absence of a sufficient protection of callus usual at this place, resulted in a ligamentous union, with slight deformity but good function. In the fifth week the hand became puffed up, reddish-blue, and much colder than the other, the nails showing a deeper tinge. By the middle of February the deltoid, the biceps, the brachialis internus, and the triceps began to respond to the will, but not to faradization, a circumstance first observed by Erb, and confirmed by others; on February 26th they contracted on faradaic irritation. Supination and pronation were first observed on March 11th, supination being less complete than pronation. On the same day flexion of the digits, excepting the thumb, was fully noticed. To-day flexion of the fingers and thumb was well marked, extension was very incomplete but noticeable, and the prognosis seemed to be decidedly hopeful. The flexors responded very well to galvanic, sluggishly to faradaic, irritation. The radial pulse was still absent.

It seemed fair to conclude, from the injuries observed and the neurotic symptoms following them, that the plexus brachialis must have suffered a very severe contusion and laceration by the displaced fragments. The statement, voluntarily made by the relatives, that the hand could be clinched shortly after the injury, seemed to indicate that no rupture of the radial and median nerves could have taken place. No special treatment with regard to the nerve-lines was instituted, attention being chiefly directed to maintaining a good general condition.

CONTUSION OF THE RADIAL NERVE.—Dr. GERSTER also exhibited another patient, who had had an injury of the radialis, caused by the fall of a heavy board on the lower portion of the posterior aspect of the arm. The patient was unable to extend the limb, and there was also the characteristic paralysis of the radialis accompanied by a flabby condition of the forearm. It was of three weeks' standing. The contusion was of the arm above the elbow.

Dr. MARKOE related a case which was pertinent to the history of the injury and subsequent progress of Dr. Gerster's first case, occurring in a gentleman forty years of age, who was run over by a carriage. Precisely how he was struck, or how he struck when he fell, it was impossible to ascertain. Dr. Markoe found fracture of the surgical neck of the humerus, which was oblique in such a manner that the upper end of the lower fragment projected into the axilla at a high situation. He was very much disturbed to find that there was no radial pulse, and there was absolute loss of sensation and motion below the middle of the arm. The hand was blue and cold, and for twenty-four

hours he apprehended the occurrence of gangrene, but this did not occur, although no brachial or radial pulse returned, and their absence had been permanent. From the time of the injury, paralysis of the muscles of the forearm was complete. Anaesthesia manifested itself particularly along the distribution of the ulnar nerve, which could be mapped out perfectly by the distribution of the paralysis, the latter being absolutely complete. After a time the patient was able to make slight flexion and extension of the fingers. He had not been able to flex the thumb. The trophic changes had been precisely as usual in these cases; the limb presented a glossy, puffy condition, and the palm of the hand particularly had exhibited a good deal of perspiration.

Appreciating that there was considerable displacement of the fragments toward the axilla, Dr. Markoe endeavored to reduce them as well as possible, but he did not dare to place any splint on the inner side of the arm, lest he should increase the injury already done by the fragment, and therefore applied a very thin pad in the axilla, leaving the arm steadied against the side of the thorax, and supporting the elbow. The case had gone on through such a history as had already been given by Dr. Gerster. In the fourth week neuralgic pains began, which were very severe and were referred especially to the palm of the hand, but extended along the ulnar side of the forearm, down the fingers, and along the dorsal aspect of the radial side. At the present time the bone was not firmly united. From the lack of support on the inner side of the arm, one unfortunate result had occurred, namely, the pectoralis and latissimus dorsi had drawn the fracture toward the chest, and pressure upon the parts in the axilla still existed to a considerable extent. Although the symptoms of paralysis had become modified, Dr. Markoe was still at some loss to know what to do further in the treatment of the case. He had used faradization only, but proposed to use the galvanic current after further trial of the faradaic. Dr. Weir Mitchell had obtained remarkable results in the treatment of the neuralgic pain so common in such cases by the use of stimulating applications to the parts to which the nerves were distributed, and had applied blisters successfully. Dr. Markoe had used strong liniments in his case for the relief of neuralgic pains, and with considerable benefit.

Dr. Post had seen cases of traumatic paralysis which had been promptly benefited by the application of moxas, either along the course of the paralyzed nerves or near the seat of injury. He had also seen marked relief follow the use of the actual cautery.

SUBCORACOID DISLOCATION OF THE HUMERUS; PARALYSIS OF THE SERRATUS MAGNUS; ARTHROTOMY.—Dr. GERSTER also presented a patient, Jennie M., twenty years of age, who had been thrown violently against a tub and sustained a subcoracoid dislocation of the humerus. The nature of the injury seemed to have been overlooked by some physicians who saw her shortly after the accident, since they treated it with liniments and electricity. Seven weeks after the injury the patient came under Dr. Gerster's care at Mt. Sinai Hospital. The diagnosis of dislocation, complicated with marked paralysis of the serratus of the corresponding side, was readily made out. Reduction did not offer the least difficulty, but the weight of the extremity alone was sufficient to cause the reappearance of the dislocation. The reduced humerus was kept in a normal position for five weeks by means of an ample plaster-of-Paris dressing enveloping the arm, shoulder, and thorax. When it was removed it was found that the tendency to the reappearance of the dislocation was unchanged, wherefore operative relief was sought for.

Arthrotomy by the anterior incision was performed on December 11, 1883. It was found that the inner aspect of the joint capsule, the side facing the axilla, was abnormally relaxed,

and therefore a piece an inch long and half an inch wide was excised from it while the arm was forcibly rotated outward. A counter-incision was made into the posterior part of the capsule, for drainage, and capillary drainage by a fascicle of catgut strands was established. The anterior wound was closed by sutures. Examinations made post mortem had revealed that, in a state of dislocation, the distance between the glenoid cavity and the apex of the head of the humerus was fully one inch.

Six hours after the operation very alarming septic fever set in, with a temperature of 103° F., and great sickness and dejection. Although no local signs of disturbance were visible, Dr. Gerster deemed it prudent to remove the stitches, open the wound, and seek for the cause of the infection. Among the seven catgut ligatures applied, three were found to be much thickened, turbid, and infiltrated with and surrounded by an areola of pus. The remainder of the wound was found to be normal, the rest of the ligatures being slightly thickened, but transparent. Suspecting the quality of the catgut used for the capillary drainage of the joints, the fascicle was likewise removed and replaced by a rubber drainage-tube. The wound was treated openly, the temperature fell to normal, and the case progressed favorably. The tube was removed at the end of the second week, and the wound healed at the end of eight weeks. Healing was retarded by an attack of erysipelas commencing from the opening made for the drainage-tube at a time when healing was nearly complete. The function of the joint was now fair, and promised to improve and become normal, since its mobility was considerable now, although very little orthopaedic treatment has been employed.

FRACTURE OF THE PATELLA.—Dr. F. LANGE presented a man, sixty-two years of age, who illustrated the usefulness of a limb after fracture of the patella, in spite of a distance of three inches between the fragments. The patient had had fracture of the patella several times. The last time the injury occurred three or four years ago, and there was also rupture of the crucial ligaments, as shown by superextension of the knee joint and great lateral mobility. The plan of treatment which Dr. Lange adopted was similar to that recommended by Dr. Little, and the immediate result was very good; but after a time the gap between the fragments began to increase, and afterward became quite extensive, measuring now three inches; yet the patient was able to walk quite well, could go up and down stairs, and could extend the limb very well.

CHOPART'S OPERATION.—Dr. McBURNEY presented a patient with the following history: William Burke, aged thirty-three, was admitted to Bellevue Hospital, December 25, 1883, suffering from severe frostbite of the extremities of both feet. The feet were dressed with soothing applications, such as charcoal poultices, up to January 17, 1884. On that day Dr. McBurney operated upon the feet; upon the right removing the toes only, at the metacarpophalangeal articulations; on the left doing Chopart's amputation at the medio-tarsal articulation. The feet and legs were first thoroughly cleansed with a solution of iodoform in ether, and irrigation with the bichloride solution, 1 to 1,000, was kept up throughout. Catgut ligatures were used, and a continuous catgut suture was applied to skin wound. A single bone drainage-tube was passed through at the base of the flap from one side to the other. The wound was covered with protective, dusted with iodoform, and enveloped in carbolized gauze and cotton, *great care being taken to force the astragalus and os calcis into extreme flexion.* To aid this effort a pasteboard splint was applied to the back of the leg and to the lower surface of the stump outside the dressing, and firmly bandaged so as to maintain the position of forced flexion. The highest temperature reached by this patient after the operation was 100° on two evenings.

The first change of dressing was made fourteen days after the operation at Dr. McBurney's clinic. The drainage-tube had disappeared, and the wound had completely healed without a drop of pus. At one point there was a minute, pin-head point of granulation.

Dr. McBurney added that, some months ago, he had reported to the society a case of Chopart's amputation, and in the discussion expressed the opinion that sufficient attention was perhaps not paid after this operation to the position given to the stump. If the stump was left to itself, the powerful extensor muscles on the back of the leg would inevitably draw the posterior end of the os calcis upward, and thus allow the cut tendons of the anterior muscles to attach themselves too far up on the astragalus. He wished to call the attention of the society to the fact that this patient could flex his short stump very freely, and that when he walked the stump had no tendency to point downward.

CASES OF EXCISION OF THE KNEE JOINT, WITH REMARKS.—Dr. McBurney then read a paper with this title. [See p. 381.]

Dr. C. T. POORE had excised nine knee joints in children varying from four to sixteen years of age, and had had good results except in two cases. In one of these the patient died six months after the excision, of abscess bursting into the lungs, from disease of the dorsal vertebrae; in the other, the child would probably die from chronic brain trouble. In the first case the consolidation of the bone was firm at the time of death; in the second, union was not firm at present. In two cases he had had the same secondary complications: in one case, necrosis of a small portion of the external aspect of the femur; in the other, of the outer portion of the head of the tibia. Recovery took place in both cases after the extraction of the sequestrum.

He had also experienced trouble from collection of pus in the synovial sac above. In some of his cases there had been more shortening than in Dr. McBurney's cases, but he thought part of it was due to atrophy of the limb from disuse. He did not think the bad issue in the two cases was due to the operation, but to the general condition of the patient. He had not seen very high temperature in any of his cases after operation. He always suspended the limbs in the after-treatment, because he thought he could take care of his patients better in this way, and it was more comfortable for them.

Dr. McBurney would like an expression of opinion as to the importance of wiring the bones together or introducing nails. He had come to the conclusion that it was not important. It seemed to him that the introduction of wires or nails, even with careful antiseptic precautions, had considerable disadvantages, as shown in several cases in which he had operated, the disadvantage being constant irritation where the wires had been brought out through the skin. The wires, however, might be buried, and the chances taken with reference to their exciting irritation. He thought the leverage of the leg was too great to allow small wires in soft bones to resist any strain upon the parts, and even where nails had been introduced, as he had understood, they had become loosened long before any firm adhesions had taken place between the bones, except perhaps in young patients.

Dr. LANGE thought that, in using nails, coaptation of the surfaces was much more intimate than it would otherwise be, and he also thought that this intimacy of coaptation secured a greater certainty of bony union than by resorting to any other method of uniting the bones. He believed, from the results of those who had resorted to this method more extensively, that the coaptation was so accurate that bony union was secured in a comparatively short time. He had found that the nails were somewhat loosened in the fourth week after the operation. But that still

they were so fixed that it required considerable force to pull them out, and that even at that period they contributed somewhat to fixation. In case we were obliged to change the dressing, the coaptation of the bones which had been secured by nails or wires remained during the change of the dressing much more accurate than when they were treated by measures which kept the coaptation less firm and accurate. This question, perhaps, was not so important now as formerly, since we had become accustomed to using permanent antiseptic dressings, so that the limb might remain untouched for months or even longer.

With regard to the advisability of excision of the knee joint in such young patients, there was always so much shortening of the limb that he was inclined to the opinion that where excision of the knee joint in a child could be avoided it was well to do so, and try to repair the injured bones without opening the joint and searching for tubercular disease, if altogether the case was such as to make this plan of treatment practicable. He had succeeded in this way in one case. In other cases the disease had been so extensive that a more extensive operation was necessary. In one case the result was a very good one, and he thought that a better chance was given for the development of the limb than would have been afforded if excision had been performed. So far as he knew, the limb might be shortened six or eight inches, so that entire disfigurement of the patient might occur in this manner.

With regard to prognosis, he thought it was much better in those cases in which ankylosis existed than in those in which fungoid disease was present. He had tried in some cases to obtain freer access to the synovial pouch by adding a longitudinal incision as high as the extension of the articular surfaces. The more fully the parts were exposed and search made for diseased synovial membrane, the more one was apt to find that small abscesses existed in the capsule and about the joint, where there were cheesy foci which explained the persistent fistula.

Dr. L. M. YALE referred to a case which had a bearing upon the question of bony union. It occurred about twenty years ago, and the operation was done by the late Dr. Enos, with the result of obtaining apparently bony union. Some time after leaving the hospital the patient fell and was brought back, when it was found that the cicatrix had torn like a piece of cloth, and the bones had separated at the line of excision. On examination, it was found that there had been partial union of the bone, as shown by what might be called stalactites running from one cut surface into the other, but at the same time the flat, sawed surfaces of the bones had united in some places by these bony prolongations, while in other places they had not. Dr. Yale replaced the limb as nearly as possible in the straight position, and the boy made a good recovery, with somewhat greater flexion than existed before the receipt of the last injury.

MEDICAL SOCIETY OF THE COUNTY OF KINGS.

PATHOLOGICAL SECTION.

Meeting of February 14, 1884.

The President, Dr. WESTBROOK, in the chair; Dr. LEUF, Secretary.

PHthisis and GASTRIC ULCER, with LOBULAR KIDNEY.—Dr. J. Y. McGAY presented specimens, and spoke as follows:

A male, twenty-four years, single, book-keeper, and born in this country, was treated about two years ago by Dr. George H. Atkinson for gastric ulcer, at which time he also had gastrorrhagia. He was under the doctor's care for several months, and received considerable relief. Then he removed to New Jersey

and put himself under the care of an irregular. During this period he gradually grew worse. Symptoms of phthisis began to manifest themselves at this time. He came under my observation about four months ago. I found that the left lung was more or less affected throughout its whole extent, as was also the apex of the right lung. Also had fever, colliquative sweats, and characteristic expectoration, with more or less cough. In addition, he had daily attacks of gastrorrhagia. There were tremendous epigastric pain and vomiting after eating anything, not even excluding the blandest foods—as oatmeal, rice, beef-tea, etc. Treatment consisted in immediately stopping all food and medicine by the mouth. His sweats were relieved by atropine hypodermically, and his cough by morphine similarly given. He received by the rectum four times a day 5 j of Reed & Carnrick's beef peptonoids dissolved in a tumblerful of luke-warm water, with gr. x of tinct. opii and 3 ss. of pepsin. This was kept up for six weeks, the patient not even swallowing 3 j of liquid of any kind, including water. The pain in the epigastrium began to disappear at once. At the end of six weeks I began to feed him with pancreatized milk by the stomach without its being followed by any bad results. Solid food was gradually introduced without any gastrorrhagia or other bad effect. He regularly became hungry and thirsty, but was relieved by the rectal feeding. Occasionally, if very thirsty, he was allowed to let some ice melt in his mouth, but always spat out the water resulting from its melting. Strange to say, about two weeks after beginning to feed by the stomach, his pulmonary trouble began to manifest itself very prominently, ran a rapid course, and resulted in his death in about a month. He was much emaciated at the time of death, but had gained in weight and strength during the time of rectal feeding. The autopsy revealed the following: There were marked pleuritic adhesions all around on both sides of the thorax. The left lung was considerably congested, especially toward its upper part. Several small emphysematous patches were found superficially on the posterior surface of its lower lobe. The apex did not crepitate, and contained many tubercular deposits, several of which had broken down and thus formed small cavities. One, however, measured about 2.5 cm. in its longest diameter, and was filled with detritus. The right lung was greatly congested, the lowest lobe being almost completely hepatized. The whole organ was more or less infiltrated with tubercle, and its cut surface was dotted with small cavities, most numerous at the apex. The heart was normal. There was an ante-mortem clot of about one half the size of an ordinary hen's egg in the left ventricle. The liver weighed 1.6 kilogramme, was congested, and very friable. The stomach was normal in size, and contained about 90 c. c. of a thick, whitish mucous fluid. The mucous membrane was of a pale-gray color at the cardiac end, but of a reddish color over the remainder of its surface, increasing in proportion as it neared the pylorus. On the mucous membrane, at the back part of the pyloric extremity, were to be seen three or four cicatrices, varying in size from 0.5 to 2 cm. in diameter. They marked the site of the ulcers from which the patient had suffered. The whole mucous membrane was thickened and softened. Both kidneys were normal. The left was a little larger than the right, and the latter was slightly lobular, in consequence of an unobliterated shallow furrow extending across the organ on its surface.

The case was discussed by Dr. WALLACE, Dr. THALLON, and Dr. McGAY.

CANCER OF THE LIVER.—Dr. WALLACE showed the specimen, and made the following remarks:

This case was that of a male, sixty-three years of age, and a very interesting case from a pathological standpoint. This case was attended throughout the greater part of its duration

by Dr. George Wackerhagen, of State Street, and probably received the best and most skillful course of treatment that could have been adopted. It is to Dr. Wackerhagen that I am indebted for the specimen. He requested me to make the post-mortem examination, which I did on the 8th of October, 1883, twenty-four hours after death.

The history of the case is as follows: In the early part of June, 1883, the patient was unwell, and grew gradually worse, until near the end of the month, when he became so much worse that he determined to go to Richfield Springs, in order to see if the change of air, etc., would not be beneficial to his health. He remained there through the month of July, and, as he got no better, but rather grew worse, he returned home on the 1st of August. While at Richfield Springs he vomited almost constantly, and quantities of coagulated blood much of the time were mixed with the vomited matters. At this period, I believe, the diagnosis of cancer of the stomach was made. After his return home the vomiting grew less, and, after a few weeks, almost entirely ceased. In the first part of September jaundice began to manifest itself, and continued, with greater or less intensity, up to the time of his death, on October 7, 1883. At the post-mortem examination the general appearance of the cadaver was sallow, or of a deep saffron hue, owing to the intensity of the jaundice at that time. There was no emaciation. On the contrary, the cadaver presented a plump and well-rounded appearance. On opening the abdominal cavity, I found a moderate amount of fluid of a light yellowish color. The quantity was from three to four pints.

On opening the thoracic cavity, the heart was found to be larger than normal, and flabby. The lungs were slightly emphysematous in patches; otherwise they were normal. Externally, the veins of the stomach were considerably congested, although the mucous coat was apparently quite normal, except near the pyloric orifice, where it bore evidence of erosion in spots, and thickening in others. The pylorus was more or less constricted by thickening of the tissues around and of the mucous membrane. The small intestines were much injected in patches where they could be seen, but were so glued together by the numerous adhesions that they could not be traced for any length continuously. They formed a heterogeneous mass, and were loaded with fat. The spleen was somewhat enlarged, about one half larger than normal, and of a very dark color. In the kidneys there was chronic interstitial nephritis with slight contraction. The capsule was adherent and the cortex thickened. The pyramids were either replaced by connective tissue or greatly contracted.

The principal lesion, however, was found in the liver. This organ was somewhat enlarged, and very firm and hard in texture. It was symmetrical, i. e., of normal shape. An immense gall-stone, three fourths of an inch or 2 cm. in diameter, was found at the point where the hepatic and cystic ducts unite to form the common bile duct. Three large gall-stones of nearly equal size were found in the gall-bladder itself. The wall of the gall-bladder was thickened throughout, the thickest part being at the distal extremity, and measuring 1 cm. in thickness. A constriction in the circumference of the lining membrane of the gall-bladder projected inward to the distance of 0.5 cm., and was situated to the distal side of the middle of the viscus. That portion of the gall-bladder on the distal side of the constriction was occupied by calculi, etc. The thickened wall of the gall-bladder was almost cartilaginous in consistence. Projecting from the left side of the distal extremity of the gall-bladder was a large nodule of scirrhous carcinoma, extending into the lobus quadratus, and measuring 3 × 5 cm. At the opposite side of the distal extremity of the gall-bladder was a similar nodule, 0.5 cm. in diameter, projecting into the right

lobe. The other parts of the liver in the vicinity of the gall-bladder contained nodules of scirrhous carcinoma, having diameters varying from 2 mm. to 1.5 cm. There were no cancerous nodules in the left lobe of the liver worthy of attention.

Dr. A. H. P. LEUF has very kindly consented, at my request, to prepare microscopic sections from the liver of this patient, some of which are excellent. It is to him, therefore, that we are indebted for a view of the minute structure of the organ in relation to the organic changes which it has undergone. These are very finely exhibited in the sections which Dr. Leuf will now show you.

The specimens were then shown.

DEATH OF THE FETUS IN UTERO.—Dr. LEUF then presented a fetus which had been born dead at full term, and Dr. G. V. CONVEY, being called on by the president, made the following remarks:

In presenting to you the causes of death of the fetus in utero, I labor under the disadvantage of want of practical experience in that branch of the medical science within the scope of which such a discussion comes. The facts that I may present here are simply the result of research, except in a few instances, where, reasoning by analogy, by contrasting those influences that may with those that have produced preparturient death, I theorize. In thus presenting the causes that may produce such death, I will not limit myself to any particular period of intra-uterine life, but shall endeavor to give the death-history of the product of conception in all the stages of its development, excepting the accidents of parturition.

The causes of pre-natal death I have, for the sake of convenience, arranged under several general heads; and I will endeavor, after taking them up *seriatim*, to give as full an exhibition of them as my feading and ability allow.

Fetal death may be caused: 1, by a vitiated condition of the spermatic fluid; 2, by diseases of the ovum; 3, by diseases of the fetus; 4, by diseases of the mother; 5, by compound pregnancy; 6, by traumatism; 7, by chemical intoxication; 8, by abnormalities of construction, monstrosities; and 9, by a vicious habit on the part of the mother.

Under the class of a vitiated condition of the spermatic fluid it has been maintained that if such spermatic fluid has the power of producing conception, its work has been done, and thenceforward the ovum is dependent wholly upon the mother for its future sustenance and development, and that the simple fact of impregnation does away with the theory of paternal weakness. On the other hand, quoting from Cazeaux, "a vitiated spermatic fluid communicates to the new being a principle that does not fail, sooner or later, to destroy it"; and Guillemot holds it to be incontrovertibly proved that strong, healthy females, who have married men, though of a suitable age, showing signs of decrepitude and early senility, have consecutively given birth to still-born children, while the issue of second marriages of the same women have been numerous and lustrous.

Passing at once to the next heading, we find that the ovum is liable to diseases which greatly compromise it, and, in some cases, may cause its death. One of these diseases is dropsy of the amnion. The normal amount of amniotic fluid is variable; but, when it exceeds three or four pints, it may be attributed to some morbid condition. This condition has been ascribed by some to a sanguineous plethora, but Dr. Mercier was of the belief that it is due to an inflammation of the amniotic membrane, and professed to have seen, in several cases, the amnion covered with false membrane. Whatever may be the morbid agent in the production of this disease, it has been noticed by many observers to occur in the subsequent pregnancies of the same woman, and to be much more frequent in twin than in single pregnancies. The immense amount of fluid in these cases

(sometimes forty or fifty pints) arrests the development of the child, and it dies in its mother's womb—though occasionally it is born alive, soon to die. If death occur at an early stage of its development, it may become dissolved in the fluid, and no trace of it afterward be found; and, in later stages, the fetus may be affected with either ascites or hydrocephalus, as we learn from the investigations of Bunsen and Kiel.

Rokitansky states that, in certain cases, adhesions more or less extensive form between the amnion and the embryo, and that these, probably the result of inflammation, may so arrest the development of the child as to cause its death.

Besides this dropsical condition of the amnion referred to, cases are met with in which the villi of the chorion become distended with fluid, giving groups of them the appearance of gooseberries. If this dropsical condition becomes general—when all, or nearly all, the chorionic villi are thus affected, the embryo dies; and in this case also may be dissolved and lost. The villi of the placenta may undergo a like degeneration, and here, after causing the death of the child, it fills the amniotic cavity, forming the blighted ovum—vesicular or hydatidiform mole—the *accephalocystis racemosa* of Laennec. Aside from this affection of the placenta, this organ may present functional derangements and textural lesions that imperil or cause dissolution of the product of conception. Plethora, congestion, and diminution in the rapidity of the circulation through the placenta may, if prolonged, so impede aeration of the fetal blood as to result disastrously.

Among the textural diseases, inflammation is the most frequent; it generally affects small areas of the placenta, but does sometimes appear extensively. This inflammation generally gives rise to plastic fibrinous infiltrations, which, reddened from the coloring matter of the blood, give rise to the large, heavy, hepatized placenta, and from the plastic deposits the placenta is nodulated. In the course of time these nodules become pale or yellow; at the same time they become dense, and the placenta, with its remaining tissue, contracts and shrivels. The inflammation in this case terminates in induration and obliteration of the placental tissue, which is converted into a tough, leathery callus, resembling yellow elastic tissue.

In rarer cases the inflammation gives rise to a purulent product, causing a diffused infiltration, circumscribed globular abscesses forming in the tissue of the placenta and general suppurative supervening—phthisis placenta. Either of these conditions will cause the death of the fetus by cutting off its blood-supply. Instances of ossification of the placenta have been mentioned by some writers, but I have been unable to glean any data of importance concerning them. Tuberculous, encephaloid, scirrhous, and fatty degenerations of the placenta have been mentioned by as many authors; but these cases were, according to Cazeaux and Rokitansky, erroneously described as such, having been obliterations of the placental tissue after inflammation, indurated inflammatory products, or old, decolorized extravasations of blood. Placental apoplexy, though generally the result of traumatism, occasionally occurs idiopathically, and, if of frequent occurrence, may result in death of the ovum. Heretofore I have used the terms fetus and embryo interchangeably; but, from the period of quickening, the product of conception is known only as the fetus, and, as such, it and its diseases we will now consider.

A most important morbid process, and one of rather frequent occurrence, the etiology of which is obscure, is inflammation. Inflammation attacks almost all the organs of the fetus, including the thymus gland and supra-renal capsules. It gives rise to plastic products with adhesions between contiguous organs, and in some cases ends in suppuration. The serous membranes are more frequently inflamed than any other tissue, and the peri-

toneum the most frequently of all. The inflammation of the peritoneum may originate in unknown causes or in causes that are demonstrable, such as constriction of the intestines, hemorrhage from the liver into the peritoneal cavity, and extravasation of the contents of the intestines or bladder.

Inflammation of the brain and resulting softening, and, in some cases, complete liquefaction of the cerebral substance, are found. Endocarditis affecting the right side of the heart, and pericarditis also, occur in fetal life, and death may ensue in the one case as a sequel to embolism, and, in the other, from interference with the heart's action. Hyperæmia and inflammation of the alimentary tract have been found, and may be accompanied by ecchymoses in the tissues and extravasations into the intestinal cavities. In the intestines, Peyer's patches are found in some cases of a "fleshy, sarcomatous" appearance, containing a grayish, curdled, flocculent fluid. These conditions resemble greatly the induration and breaking down of the Peyerian glands in typhoid fever, and may result, says Rokitsansky, if not from an identical cause, from a very similar one. Autopsies on fetuses have also shown a diffused croupous inflammation of the intestinal mucous membrane.

In the respiratory apparatus we may find disease; hepatization and even abscesses have been seen in the lungs.

The liver of the fetus is often the seat of congestion and hyperæmia, and, from the delicacy of the tissue, apoplexy and rupture occasionally occur. Infiltration into the hepatic tissue may form, giving the fatty, waxy, and lardaceous livers.

The urinary organs of the fetus do not often become diseased, but in a few cases apoplexy of the kidney is found, and supuration of the supra-renal capsule occurs; and, from contraction or an impervious condition of the urinary passages, the bladder has been found ruptured.

The fetus is not only affected with these local diseases, but may suffer from the various zymoses, and may even die; and this either while the mother is coincidentally affected, or independently of her. The fetus may become affected with variola, even though the mother never had the disease; this fact is attested by Bouchut, Rokitsansky, Jenner, Deneux, and others.

If malarial toxæmia is ever the cause of death, I think it might be noted as a possible cause of pre-natal death, especially in those localities where the malarial miasm is of a virulent character; for it has been proved by several observers (Stokes, Schurig, Jacquemier) that women affected with malarial toxæmia may communicate the disease to the fetus. Finally, there is one disease which I put in this category, first, because the fetus becomes affected with it, and, secondly, because it enables me to dodge the question as to whether it is communicated by the father or the mother; and that disease is syphilis. Of all the diseases to which humanity is heir, none compares in destructive ability with syphilis. Various is its mode of action, in fact, many if not all of the lesions of the fetal organs may be due to the action of this poison; inflammation, abscess, and supuration of the different organs have been ascribed to it by many authors, and monsters of arrested or perverted growth by others.

Without spending any more time on diseases of the fetus, we pass at once to diseases of the mother. The diseases of the mother that sometimes produce death of the fetus in utero are few; and some of them have already been noticed when speaking of diseases of the fetus. Variola, as we have seen, scarlatina, and measles may be communicated to the fetus and result in its death. Typhoid fever and pneumonia have been observed to cause the death and expulsion of the contents of the uterus; and Asiatic cholera has produced like results, but probably from the spasms more than any transmission of the disease. Uremia, with marked convulsions, may result in like manner, and severe

cases of albuminuria have, in the opinion of Cazeaux, Cohen, and Rayer, caused the death of the fetus.

Taking up compound pregnancy as a cause of preparturient death, we find that one of the fetuses may die, yet the other continue to grow. In these cases the dead fetus remains in the uterus, where it withers and hardens, and is expelled during labor. In other cases the dead twin may remain in the womb, in consequence of adhesion, for a long time after the birth of its brother; and one case is recorded by Guillemot in which the artificial extraction did not take place until two years afterward. The cause of death of one fetus was attributed by Mauriceau and Peü to the fact that one child, by receiving all the nourishment, becomes strong and vigorous at the expense of the other, thereby rendering it feeble and causing its death. Guillemot believed that one child, in its growth, gradually compressed the second against the uterine wall, and that the latter, not having sufficient space for its development, soon after died. Other authors are of the opinion that, in the cases where death of one fetus takes place, the cause should be attributed to some disease of the ovum, fetus, or placenta. What is said of twin pregnancies applies with equal force to cases of triplets, etc. Thus, in the case cited by Portal, after the delivery of the first child and its placenta, which were healthy, he was obliged to extract two others that had apparently been dead a long time, and were thoroughly dried.

Traumatism may cause the death of the fetus, either by direct injury to the fetus itself or to the placenta or umbilical cord. Some females will go through almost any kind of accident and yet give birth to a living child; yet, in other cases, very slight injuries will cause fetal death. Cazeaux gives us the case of a woman, six months pregnant, who struck her abdomen against a table while walking through a dark room; during the night the motions of the child were for a time quite tumultuous, then they diminished, and on the following day were not perceptible at all. Two days afterward she was delivered of a dead child, which presented an ecchymosis on its back as large as the palm of an adult hand. Burdach speaks of a woman who received a blow upon the lower part of the abdomen when in the sixth month, and was delivered of a child the bones of whose right leg and of a forearm were fractured. Blows, concussions, and shocks to the abdomen may also cause apoplexy and separation of the placenta; also rupture of some of the umbilical vessels. Under the heading of traumatism should come also cases of extreme shortness, true knots, and preternatural length of the umbilical cord, as these conditions may result in the preparturient death of the fetus by, in the first case, rupture from traction, and in the others from compression of the vessels, thus interfering with the fetal circulation. I make no mention here of traumatism as applied with criminal intent; in like manner I refrain from mentioning chemical substances used for the same purpose, referring the curious to the lists of Tidy, or any other work on forensic medicine.

Chemical Intoxication.—In 1859 Dr. Constantin Paul made a study of the effects of lead upon pregnancy. He observed the case of a woman who had been three times safely delivered before being exposed to the influence of lead, and who afterward, out of ten pregnancies, had eight miscarriages, one still-born child, and but one that was born at term, but which died five months afterward. Dr. Paul thought that this great mortality might be due to the action of lead. The woman also informed him that almost all her companions in the establishment in which she worked either miscarried or were unable to raise their children. He then began his investigations. He found from these investigations eighty-one cases of women in whom lead-poisoning caused either the death of the fetus or

the premature death of the child after birth; also miscarriages at from three to six months, and premature labors in which the children were born either dead or in a dying condition. Without going in detail through the different series of Dr. Paul, we find that the fetus in utero may either become affected with lead-poisoning while the mother is so suffering, or the fetus may become affected and die while the mother shows no evidence of such intoxication; and, from the fact that out of 123 pregnancies there were 64 abortions, 4 premature births, and 5 still-born children, and presuming that many of the 64 abortions were connected with intra-uterine death, we readily see the disastrous effect of this chemical agent. While I have been unable to gather any material relating to arsenic in this connection, I think it reasonable to suppose that it may have a like action. When we consider the large amounts of lead and arsenic that are used by ladies in depilatories, cosmetics, and lotions, as shown by the analysis of Professor Chandler, and recollecting the case of "Bloom-of-Youth" poisoning mentioned by Dr. Sayre, a macroscopic examination of the mother's studio would, in some cases, I think, give greater results than microscopical and pathological investigations.

There are certain meteoric influences that may have some action on the life of the fetus, and can be better noticed at this time than at any other. On the Vosges Mountains, where cretinism and goitre are prevalent, miscarriages are so frequent that females living on these mountains are in the habit of descending to the adjacent plains to be enabled to go on to term. May not these abortions in many cases be the result of previous death of the fetus, for does not the prevalence of cretinism show that the development of the fetus is interfered with?

Regarding abnormalities of construction or monstrosities there is but little to say. In certain cases, consisting in a diminution of the normal number of organic parts, the fetus may reach a certain stage of development, and then die. Of one class are the *anencephali*, which, though occasionally born alive, generally die before term. Of another class is the *acardiac monster*, which is never born alive—and sometimes the two forms are found in one fetus. Many more classes might be mentioned, but it is needless. These monstrosities are the result of arrested development, due to inflammation or some specific morbid agency—probably syphilis. The last division of the cause of death of the fetus in utero that I have made is certainly not a scientific one; but it serves to cover that class of cases in which certain females give birth consecutively to still-born children without any appreciable cause being found either in the father, mother, or child itself. These females generally give birth to the dead child at particular months of their pregnancy—seldom before or after; Cazeaux records the case of one who gave birth to a still-born child thirteen times in succession during the last month of utero-gestation, and nothing could be found to account for it except idiosyncrasy or a vicious habit.

These, Mr. President and gentlemen, are some of the causes of preparturient death of the fetus, some of which may be recognized by the acute observer; and, on the removal of such—if removable—the mother will be enabled to give birth to the normal fruit of her conception instead of some hideous, dwarfed, or unrecognizable product of a vitiated uterine life.

Dr. JEWETT closed the discussion, after which the society adjourned.

NEW YORK OBSTETRICAL SOCIETY.

A STATED meeting was held November 20, 1883, Dr. W. M. POLK, President, in the chair.

SARCOMA OF THE CERVIX UTERI.—Dr. JAMES B. HUNTER presented a specimen which he had removed at the Skin and Can-

cer Hospital from a patient sent to him by Dr. Arango and Dr. Townshend. She was thirty-seven years of age, and the mother of one child. On examination by the vagina, a mass could be felt, bleeding easily, apparently malignant in character, and connected with the cervix uteri. It gave rise to considerable hæmorrhage, but not to pain. On the 24th of October the patient was placed under ether, and the growth was removed with the spoon-saw and scissors. It was found to be attached to the posterior lip only, but the attachment extended from the external to the internal os. Microscopical examination proved the growth to be a spindle-celled sarcoma. The patient made a good, but somewhat slow recovery. Dr. Hunter had found it rare for sarcoma to develop in the cervix uteri.

Dr. HENRY J. GARRIGUES said that, while sarcomatous growths from the cervix were indeed comparatively rare, they seemed not to be so rare as had been supposed. This was the third case which had come to his knowledge within less than a year. The first case occurred in the practice of Dr. Burke, of South Norwalk, Conn., and the specimen was referred to Dr. Garrigues for examination, and was reported on at the meeting of December 20, 1882. The second case was that of an old woman, from whom Dr. Garrigues removed the sarcomatous growth by means of Simon's spoon and Paquelin's cautery. The patient died of peritonitis. In those two cases the affection was the small-round-celled sarcoma. Dr. Hunter had just related the third case.

Dr. JOHN G. PERRY asked Dr. Hunter whether the growth had not originated in the cavity of the uterus and afterward become attached to the cervix.

Dr. HUNTER replied that it had evidently developed from the cervix in the first instance.

Dr. JOHN BYRNE said that some years ago he removed what was regarded as a vascular tumor from the posterior lip of the uterus, and found that there still remained a projection from the posterior cervical wall, interfering somewhat with the passage of the sound. Microscopical examination showed that the growth removed was sarcomatous in character, and he then regretted not having removed the entire tumor. The patient had only suffered pain at the monthly periods. Two months ago she returned with the same symptom, and, on examination, the growth in the cervix was found to have remained stationary. Was it possible for sarcoma to remain quiescent for so many years?

Dr. GARRIGUES thought it was possible that a mistake had been made as to the true character of the growth, based on the microscopical examination. As the President had suggested, the fungous growths of a chronic endometritis often presented the characteristics of diffuse sarcoma, and the two could be distinguished only by their clinical history.

Dr. B. F. DAWSON reported further on the case of papillomatous cyst related at the last meeting. The patient did very well until the sixth day, when absorbent cotton carried into the drainage-tube showed slight signs of the presence of pus. Dr. Wilcox, the house surgeon, sent him word in the evening that the patient complained of pressure about the heart, and of numbness of the left leg and arm, that the tongue did not deviate to the left, but that there was some difficulty of speech, and that the pupils were normal.

Dr. Dawson immediately visited the patient, and found the temperature was 100.4° F. The tube, on being examined, was found to contain pus, which Dr. Dawson believed was probably due to part of the discharges from the wound under the seat of the clamp entering the peritoneal cavity alongside the drainage-tube. He decided, therefore, to remove the clamp, and adapted a hard-rubber Hodge pessary, flattened out, to take its place in holding the stump in the abdominal wound by silver wire twisted around the pedicle, the ends being fastened to the side

of the pessary resting over the wound. The temperature began to fall in a few hours, and the patient soon felt better. Similar symptoms again developed about the tenth day, but disappeared on emptying a mural abscess. The drainage-tube was allowed to remain until the ninth day, when he was sure that an impervious wall of lymph had formed around it, and then its place was immediately supplied for a few hours by a roll of absorbent cotton, renewed twice. Three days ago a slight discharge had taken place from the vagina, but he did not think it due to the clamp, as this had been applied so low down on the fundus as to involve the cavity. He considered the patient out of danger. Dr. Dawson thought that doubtless death had resulted in more than one case, from the presence of the clamp, which might have been avoided by early substituting the pessary and wire or other support for the pedicles.

TWO CASES OF VICARIOUS MENSTRUATION.—Dr. GARRIGUES related the following cases: One was that of a woman, forty years of age, who had ceased to menstruate a year and a half before, since which time she had constantly had what she called "milk in the breasts." It consisted of a thick, yellowish-white fluid, which, on microscopical examination, was found to be colostrum. He prescribed Carlsbad salt internally, and belladonna locally. He had seen the patient but twice. The second case was that of a woman, forty-seven years of age, in whom the menopause had taken place fifteen months before. In her case there was constant and profuse perspiration over the entire body. Tincture of belladonna was prescribed internally. She had not been seen since.

Dr. A. JACOBI had seen two cases of a discharge of milky fluid from the breasts after the menopause. In one it occurred in a woman about seventy years of age, who made no complaint, and therefore was not subjected to treatment. The other case was observed many years ago, and was taken for vicarious menstruation. The patient improved within six or eight weeks under the influence of cold locally and ergot internally. In that case there were very large fatty granules in the secretion, as was also true of colostrum.

Dr. PERRY had seen three cases of excessive perspiration following the change of life—all of them in unmarried women. He had considered it due to a neurosis, and treated it by rest and regulated nutrition. Two of the patients quickly recovered. In the other case the trouble lingered for two or three years, and was not relieved until after a sea voyage.

The PRESIDENT said that about three years ago a patient came under his care who had not menstruated for six months. The abdomen was enlarged, the breasts contained milk, and she supposed she was pregnant. The uterus was found to contain a fibroid tumor, but no fetus.

Dr. GARRIGUES referred to the sympathetic relation between the mammae and the genitals, which was illustrated in the case of a virgin, both of whose breasts secreted milk for three or four days following an intra-uterine injection of a dilute solution of chloride of iron, given to arrest hemorrhage from a fibroid.

Dr. CLEMENT CLEVELAND had seen a woman, fifty-three years of age, who, since ceasing to menstruate, at the forty-fifth year, had had a monthly bloody discharge from the nipple. She had been under his observation for about two years, and he had considered the case to be one of vicarious menstruation.

LOCAL EDEMA, CONFINED ABOUT THE EYE, DURING MENSTRUATION.—Dr. RACHE McE. EMMET related the case of an unmarried lady, aged thirty-two, who, at each menstrual period, had a localized oedematous condition of the face, confined about the left eye and the lids, together with ptosis. The sight was not affected except by the swelling of the lid. He regarded the condition as due to a neurosis, and it had temporarily improved

with restoration of the general health. There also existed an obstinate eczema about the genitals.

Dr. JACOBI thought the case related by Dr. Emmet specially interesting in the absence of pain.

PERSISTENT FLACIDITY OF THE UTERUS AFTER DELIVERY.—Dr. PERRY related the case of a lady, thirty-eight years of age, the mother of five children, the youngest being four years old. She had complained, since the birth of this youngest child, of bearing-down pain and inability to stand or walk, from the great pressure and weight in the pelvis. Menstruation occurred every three weeks, and lasted, with scanty flow, seven and eight days. On making a vaginal examination, he found the cervix in its proper position, but very short and flaccid, and, extending around it in a circular direction, a soft mass, apparently the result of a pelvic inflammation. On conjoined manipulation, the mass appeared very shallow, but nowhere could he find the fundus of the uterus. A sound was introduced, which penetrated but two inches. Not doubting that it was within the uterine canal, he essayed a little force, and with this was able to penetrate to the depth of eight inches, and, while doing so, found that the mass in the pelvis disappeared. He had, indeed, while forcing the sound upward, carried the uterine wall before it. An electrode was substituted for the sound, and a current of galvanism conveyed to the endometrium. This was done from day to day, without, at first, eliciting more than a slight flow of blood; but in time contractions followed, and finally sufficient firmness was established to justify the use of a vaginal support. At this juncture ergot and galvanism were used together, and a complete cure was eventually established. The patient had since become pregnant, and promised to do well. Dr. Perry thought this a case of subinvolution resulting from sudden and complete cessation of contraction after labor, leaving the uterus in a state of collapse; but he thought some might regard it as essentially a case of paralysis.

Dr. JACOBI thought that the treatment by electricity should vary according to the view taken of the cause of the condition. In cases of paralysis of certain muscles, or groups of muscles, relief was sometimes obtained by applying electricity to the nerve centers. The quick result following the application of galvanism to the uterus in this case would rather point to subinvolution being the cause of the paralytic condition. So soon as absorption of the abnormal, hyperplastic material had been accomplished by the action of the galvanic current, the uterus resumed nearly its normal shape.

Dr. ROBERT WATTS said that two similar cases had been related to the society, one of which occurred in a patient at Charity Hospital some years ago. On making an examination, he passed the sound a distance of nine inches up the uterine cavity, and it could be felt through the abdominal wall. It was believed that the sound had passed through the uterine wall, and an attack of peritonitis was awaited. The patient had no bad symptom, however, and the procedure was repeated several times afterward by different physicians. Dr. Isaac E. Taylor called the case one of "balloon uterus." The other case was similar, the sound passing a distance of eight inches and a half.

The PRESIDENT referred to his experience in hospital practice with Hegar's method, a modification of Simon's, for the examination of the pelvic organs, which he considered much superior to the ordinary method by conjoined manipulation. In his experience it had not been attended by any bad results. In many cases, he believed, the true condition could be determined with more certainty by this method.

BENJAMIN F. DAWSON, M. D.,

FRANK P. FOSTER, M. D., *ex officio*,

Committee on Publication.

Reports on the Progress of Medicine.

PSYCHOLOGICAL MEDICINE.

By J. LEONARD CORNING, M.D.

BILATERAL HALLUCINATIONS DIFFERING IN CHARACTER ACCORDING TO THE SIDE AFFECTED.—Magnan ("Archives de neurologie," Nov., 1883) draws attention to the fact that, as a rule, hallucinations affect the two symmetrical halves of the same sensory apparatus; that is to say, that the victims of hallucinations, like those of normal constitution, hear with two ears, see with two eyes, perceive, in a word, with both sides the subjective images which they ascribe to the environment. Under certain circumstances, as already noted by several observers, the hallucination is unilateral and affects one of the symmetrical halves. Where this condition exists the individual is dominated by one eye, one ear, or one side of the body.

In a still rarer category of cases the hallucination is bilateral, but manifests itself with variable characteristics, according to the side affected. Thus, the right ear, for example, hears things of an agreeable nature, whereas the left ear receives nothing but dismal impressions. The latter is a phenomenon which, up to the present time, has by no means received the attention which it deserves.

Several cases are cited by Magnan illustrative of this curious condition. In one of these instances of bilateral hallucinations, occurring in an old soldier, the disagreeable impressions were confined to the left side, whereas those of a pleasant character were manifest upon the right. The subject had been addicted to alcoholic excesses, and had consequently suffered on several occasions from delirium tremens, accompanied by various horrible hallucinations of sight and hearing. He had been treated twice at the Asile Sainte-Anne. The last time he was treated at that institution he complained of hearing voices, one of which abused while the other consoled him. The insulting voice spoke into his left ear, in an abusive manner, calling him an imbecile and criticising his work; the protecting voice, on the other hand, interfered at the right ear, consoling and encouraging him. Such phenomena are considered by the author to constitute additional proof of the duality and functional independence of the cerebral hemispheres.

In summarizing the results of his observations he concludes: 1. That bilateral hallucinations possessing different characteristics, according to the affected side, are independent of any organic change in the peripheral organs. 2. That they do not differ from other hallucinations either in their mode of appearance, in the manner of their evolution, or in their general characteristics. They pursue a parallel course to the delirium. 3. They are an additional proof of the duality and functional independence of the cerebral hemispheres, and they point to the sensory centers of the cortex as the organic seat. 4. The experiments performed during the different stages of hypnotism and hysteria confirm clinical observation in every point.

SUDDEN DEATH DURING THE HYSTERICAL CRISIS.—Molliére ("Lyon médical," Nov., 1883) presents a critical review of a number of cases of hysteria reported by Regnier de Graaf, Morgagni, Rullier, Piorry, and others, in which death transpired during the crisis. From an analysis of these cases, as well as from careful study of a case occurring in his own service, at the Hôpital de la Croix-Rousse, in which a careful post-mortem examination of the brain and medulla was made, twenty-four hours after death, the author feels justified in arriving at the following conclusions: 1. If hysteria depends for its existence upon some specific organic lesion, the latter is entirely unknown to us at present. 2. Until a new order of things, therefore, the great

neurosis must remain in the category of the *maladies sine materia*, or rather of those in which the dynamic state of the anatomical elements is alone called in question. 3. Moreover, in almost all the cases analyzed, the fatal termination was intimately connected with the phenomena of asphyxia, occurring with more or less rapidity, but always perfectly recognizable.

PROGNOSIS IN CASES OF MENTAL DISEASE.—Sankey ("Liverpool Medico-Chirurgical Journal," January, 1884) has tabulated the more important conditions which characterize the early stages of the incurable and curable forms of mental disease. The inquiry resolves itself into a determination as to (1) whether the case is one of general paralysis (incurable form), or (2) whether it represents an instance of ordinary insanity. By "ordinary" insanity is understood all curable forms of mental disease (except general paralysis).

The positive evidence bearing upon the question as to whether a given case of mental disease belongs in the category of curability or incurability, as above understood, may be broadly summarized as follows (when the attack is primary):

1. The mode of the invasion in ordinary insanity, in a primary attack, will be by melancholy. General paralysis, as a rule, commences by the opposite rather, as by hilarity, busy occupation, absurd conduct, garrulity, and want of ordinary reticence on every subject.

2. In ordinary insanity the emotions alone are affected, as by depression and grief, sense of wickedness or being blameworthy, morbid apprehension, as of ruin, injury, poison, loss of salvation, etc.

In general paralysis all the faculties are in a state of exaltation, the emotions, the intellect, and volitions being equally involved, and the conduct is wild and irrational.

3. In the melancholy of ordinary insanity the patient wishes for solitude. In general paralysis the patient rushes into all kinds of society.

4. In ordinary insanity the commencement of the symptoms is gradual, insidious, often obscure, and occurring in persons of quiet temperament. In general paralysis it follows very often upon some great mental shock, and almost suddenly, and occurs in persons of sanguine temperament and great activity of mind. The evidence contained in the history of the case should be examined both from a negative and positive standpoint.

As general paralysis is almost invariably fatal, it is evident that there can be no true second attack. It should, however, be borne in mind that the disease is liable, under certain circumstances, to remission of all symptoms. Such a remission may last for several years, giving rise to the erroneous belief that the disease, after all, is not a case of general paralysis.

Where we have to do with a secondary attack of mental disease, which has taken place after a period of apparently complete recovery, the probability of restoration is greater than in primary cases. At the same time, however, all things being equal, the prospect of a third and subsequent attack is greatly enhanced. This is particularly true where there is a persistence of the exciting cause, as in the puerperal condition. When the secondary attacks become progressively less severe the prospect of ultimate complete recovery is proportionately increased.

TWO CASES OF INSANITY IMPROVED BY AN ANTHRAX.—Fusier ("L'Encéphale," Jan., Feb., 1884) gives the history of a case of mania and also of one of melancholia in which the advent and subsequent opening of an anthrax in the dorsal region were followed by immediate and permanent amelioration of all the symptoms. A very noteworthy feature in these cases was the deep and prolonged sleep which supervened after the opening of the abscesses, from which the patients awoke with marked evidence of mental improvement.

[One can not read these cases attentively without feeling

convinced that the marked mental benefit is attributable to the *prolonged sleep*, during which a reform was inaugurated in cerebral nutrition, culminating in a permanent restoration of the normal dynamics of the cell. In the first case cited, this period of profound sleep lasted eleven hours.—J. L. C.]

THE REFUSAL OF FOOD BY THE INSANE, WITH REMARKS ON TREATMENT.—SIEMENS ("Archiv für Psychiatric und Nervenkrankheiten," XIV. Band, 3. Heft, 1893), in an elaborate paper, has endeavored to show how far it is possible to treat the refusal of food by insane patients, upon a scientific basis, without the use of restraint. The dangers which may result from the use of the stomach-pump and sound are made the subject of elaborate discussion; and numerous instances are cited where the sound has entered the trachea instead of the oesophagus, giving rise to direct injuries of a severe nature, or resulting in pneumonias caused by the entrance of particles of food into the bronchi, or, in some cases, in immediate asphyxia. A case is cited where even a surgeon of great experience was so unfortunate as to thrust the sound of an ordinary stomach-pump through the aorta, owing to a movement on the part of the patient.

[The subsequent remarks upon scientific alimentation, while eminently credible, will appear somewhat utopian to those who have had some practical experience with this class of cases in asylum practice. Moreover, the dangers incident to the introduction of sounds into the oesophagus seem to us somewhat exaggerated. We have had occasion to undertake this procedure several hundred times in asylum practice without even the approach to an accident. The time has certainly not yet arrived when the sound can be banished from the wards of lunatic hospitals.—J. L. C.]

THE PULMONARY PATHOLOGY OF GENERAL PARALYSIS.—CRICHTON BROWNE ("Brain," Oct., 1883) draws attention to the fact that, although the pathological processes found in general paralysis of the insane which possess most importance are such as are located in the central nervous system, there is, nevertheless, a category of secondary morphological phenomena which, though much neglected, are deserving of careful study.

Thus, among the secondary degenerations of general paralysis, those that affect the lungs are not the least conspicuous and important. In a large percentage of autopsies performed upon individuals who have succumbed from the effects of this disease, coarse changes in the pulmonary structure are plainly visible, and in many cases these are of a nature which indicates that they have interrupted the progress of the cerebral disorder, and prematurely brought to a close the unhappy existence of the sufferer.

Dr. Crichton Browne has tabulated his observations upon the pulmonary condition of one hundred patients—eighty males and twenty females—who died in the West Riding Asylum between April, 1872, and August, 1875. The average age of these patients at the time of death was forty-one years and seven months in the men, and forty-two years and five months in the women; and the average duration of asylum treatment was sixteen months and two weeks for the men, and twenty-four months and one week for the women. The earliest age at which death from general paralysis occurred was twenty-four years in a man, and thirty-two years in a woman; and the greatest age at which it occurred was fifty-five years in a man and fifty-seven years in a woman. The average age for the incursion of the disease is about the same for both sexes—viz., forty years; but the advance of the malady is more rapid and violent in men than it is in women.

It is to be noted that where intercurrent maladies appeared in the course of these cases they did not set in till the fourth or last stage of the disease. The first point to which the author

directed his attention, in connection with the inquiry concerning the pulmonary pathology of the disease, was the weight of the lungs. The mean weight in the male was found to be 26½ ounces for the right and 24 ounces for the left lung. In the female the mean weight of the right lung was found to be 18½ ounces, and that of the left 15½ ounces. As the author remarks, these figures are so greatly in excess of all standard lung-weights that it is obvious that they have been raised in the case of general paralysis by morbid conditions of the lungs, the influence of which is also apparent in the enormous difference between the highest and lowest weights, as shown in the table [males: highest, 46.75; lowest, 13.00. Females: highest, 31.00; lowest, 7.50].

Table III exhibits the state of the pleuræ in one hundred cases. In thirty-six cases the pleuræ on both sides were found, free from adhesions and normal, whereas in sixty-two instances adhesions were present. Fluid was present in the pleural cavities in two cases.

Congestion of the lungs—the most common pulmonary accident in general paralysis—was present to a marked degree in forty-nine (49) out of the one hundred (100) cases analyzed. The amount of congestion varied from slight hyperæmia, with some serous infiltration of the pulmonary parenchyma, up to extensive engorgement of a dark-red, or even blackish color.

A distinct pneumonic condition of the lungs was found in thirteen (13) out of the one hundred (100) cases of general paralysis. Dr. Crichton Browne concludes, with regard to the causation of these pulmonary inflammations in general paresis, that, "as in the acute and chronic decubitus of general paralysis, we are forced to assume that, besides mechanical irritation, some centric nervous influence is at work, causing neuro-paralytic hyperæmia, and, perhaps, a suspension of healthy trophic influences, for the existence of trophic fibers in the lungs is not yet finally disproved."

The author aptly observes, when discussing these phthisical symptoms, that, until Koch's theory is disproved, it would be prudent to act on the assumption that it is true, and to prevent the close association of persons actually suffering from phthisis with those who, from inherent tendency or deterioration of health, are especially liable to contract the disease.

Abscess of the lung was observed in two cases out of the one hundred examined.

Gangrene of the lung, however, did not occur in any of the one hundred cases analyzed.

HYSTERIA: A STUDY IN PSYCHOLOGY.—LLOYD ("Journ. of Nervous and Mental Disease," Oct., 1883) attempts to "unfold" some of the psychological features of hysteria. The ideas of the ancients respecting the nature of hysteria were fantastic to a degree. Thus, Paul of Ægina believed the cause of the disease was to be ascribed to putrid semen in the womb. Hippocrates, on the other hand, affirmed that it was most frequently encountered among elderly virgins and young widows. Plato says that it is the expression of indignation on the part of the womb, which, being unable to generate, wanders about the body, and stops the passage of the spirits and respiration. The idea of uterine or ovarian agency in the production of hysterical symptoms is, however, by no means confined to the ancients, but, on the contrary, finds support among observers of reputation in the modern medical world. Charcot, indeed, asserts that he can arrest a severe fit by pressure on the ovary. Rosenthal believes the primary causes of the disease are resident in the cord. Conolly maintains that the disease arises from a morbid susceptibility of the nervous system. The difficulty with these conceptions of more recent writers concerning the causative factors of the disease is found in their evident crudity and their inadequacy to account for the psychical phenomena.

A very interesting instance is given of "hysterical" symp-

toms occurring in a young Irishman. From the evidence contained in this case the author draws the following inferences: That hysterical symptoms are not always due to the womb or ovaries; secondly, that sometimes they can not be linked to any bodily organ; and, lastly, that they are in most cases, if not *all*, due to abnormal states of consciousness. Healthful consciousness has "many modes of action." Thus we have *sensational* consciousness, or knowledge of impressions from the outside world. Following upon sensation there are two other psychical states, which alternate with one another—the *intellectual* and *emotional* modes of consciousness. Besides these we have the consciousness of memory and volition.

Consciousness is defined as a condition of self-knowledge in relation to the exterior world. [Not a bad definition. Consciousness is, however, best understood by a careful analysis of its evolution. Such an analysis, from a more or less physiological point of view, is given by Luys. Definitions are apt to be either long and unwieldy, or, when brief, to be crude and inadequate.—J. L. C.]

From a physiological point of view, the author thinks, there would be no objection to accept, for these various psychological districts, the term *center*. It is a lack of due co-ordination between the various centers which gives to hysterical affections their most pregnant characteristics. Moreover, the nervous system may be regarded as a mechanical arrangement for the expression of certain reflex actions. It is in this very mechanical or reflex action of the lower ganglia in the cord, and the ganglia of special sensation and also the highest centers of the brain, that many of the characteristics of hysteria are to be sought. In a word, the sphere of this disease is more especially limited to the automatic action of the brain and cord.

Both the causation and symptomatology of hysteria receive considerable attention. The article is carefully written.

THE CONDITION OF MUSCULAR FORCE IN GENERAL PARETICS.—Descourties ("L'Encéphale," Jan., Feb., 1884) has measured, by means of the dynamometer of Mathieu, the strength of a large number of individuals suffering from general paralysis, at various stages of the disease. Due allowance being made for the sources of error inherent in the dynamometer, which the author is at some pains to point out, the following are some of the conclusions arrived at: 1. The strength of general paretics is usually diminished from the inception of the malady. The pressure, estimated by means of the dynamometer, amounts to an average of 34.7 for the right and 30.2 for the left, instead of 54.3 for the right and 47.1 for the left, which represent the normal average. 2. This loss of strength is about equally distributed upon the right and left sides. 3. It does not follow a continuous course. The author believes that the knowledge gained by means of the dynamometer will often enable the physician to adopt prophylactic measures impossible under other circumstances.

DEFINITIONS OF INSANITY.—Huggard ("Jour. of Mental Science," Jan., 1884), after criticising the inherent defects of previous attempts at definition, speaks of insanity as "any mental defect that renders a person unable to conform to the requirements of society." It is impossible to epitomize the arguments adduced by the author in favor of his individual views on this delicate and much-contested point. The article is suggestive, however, and will repay a perusal.

THE PATHOLOGY OF MANIA.—Wigglesworth (*ibid.*) defines mania as a disease involving disorder of the relational elements of mind, and of a greater or less number of these, according to the intensity of the disease; in other words, what we clinically know as mania has for its material substratum an affection, functional or organic, of the higher co-ordinating plexuses of the brain.

HEREPHRENIA, OR INSANITY OF PUBERTY.—Ball ("L'Encéphale," Jan., Feb., 1884) expresses his opinion respecting the reason for the occurrence of insanity at the age of puberty as follows: The reflex phenomena, which play so prominent a part in grown men, attain the maximum of their development in the child, as Maudsley has pertinently remarked. The majority of intellectual and moral operations performed during the first years of life are sensory and motor reflexes. Automatism plays an immense part during this period of development; and it is only by degrees that individual action is developed, which is sustained by judgment, experience, and volition. Puberty is therefore the epoch at which the greatest psychological transitions take place, and at which the mind is particularly susceptible to the inroads of mental disease. The unfavorable prognosis is, moreover, attributable to the mental arrest which is liable to arise from insanity occurring at this period.

Miscellany.

THERAPEUTICAL NOTES.—*Phosphide of Zinc*.—In a recent number of the "Gazette hebdomadaire de médecine et de chirurgie" M. Paul Vigier remarks that, although phosphide of zinc contains twenty-five per cent. of phosphorus, it requires to be given in doses eight times as large as those of phosphorus, for in the system its phosphorus enters into combination with hydrogen, and in that state has only half the activity of phosphorus. Leaving the question of dose out of account, however, much of the disappointment that has been met with in the use of the drug is no doubt to be ascribed to an imperfect salt having been used. In the process of making phosphide of zinc, the salt forms in two different states, one part of it subliming, and the other forming a gray, friable mass. The latter form predominates in the process of manufacture, but is very variable in its percentage of phosphorus. An eighty-per-cent. phosphide answers every purpose, but all below sixty per cent. should be rejected. The following convenient method of assay is given: 0.586 gramme of the phosphide, wrapped in a piece of cigarette-paper, is introduced into a graduated gasometer, inverted over mercury, and containing 8 c. cm. of hydrochloric acid. If the phosphide is pure, it ought to disengage 100 c. cm. of phosphorated hydrogen completely absorbable by a concentrated solution of sulphate of copper, an eighty-per-cent. phosphide will disengage 80 c. cm. of the gas, and so on.

THE COUNTY SOCIETY AND THE COLLEGE OF MIDWIFERY.—The following is the full text of the minority report presented at the last meeting of the Medical Society of the County of New York by Dr. A. W. Warden (not Dr. Ralph Waldo, as erroneously stated in our report of the meeting in last week's journal):

"The undersigned, a part of your committee appointed to investigate and report to the Medical Society of the County of New York concerning two acts proposed for State legislation presented to the Medical Society of the County of New York for approval, by the promoters of the proposed New York Maternity and School of Midwifery, reports as follows:

"*First*, in regard to the proposed New York Maternity and School of Midwifery, your committee do recommend that the Medical Society of the County of New York do not indorse or commend the incorporation of such an institution, because not conducive to the elevation of the medical profession and the good of the community.

"*Secondly*, in regard to the proposed 'Act in Relation to the Practice of Midwifery in the State of New York,' your committee find such proposed law to be not advisable, and counsel that the Medical Society of the County of New York, in the interest of maintaining a high standard of qualification for the practice of midwifery and all branches of the profession of medicine, and in the interests of the people of the State of New York, do not approve any State legislation giving the

right to practice midwifery or any branch of the profession of medicine to persons other than qualified and registered (male and female) physicians.

[Signed]

"A. W. WARDEN, M. D."

THE CONTAGIOUSNESS OF ERYSIPELAS.—The following summary, from a paper by Dr. H. F. A. Goodridge, in the "Practitioner" for December, 1883, concisely exhibits the position he occupies with reference to this question:

1. Many authorities concur with Mr. T. Holmes in regarding erysipelas as only feebly contagious, e. g., Billroth, who says: "It is propagated by a contagium which is considerably less infectious than that of measles or scarlet fever." The difficulty, according to recorded testimony, of producing the disease artificially would seem to tell much in favor of this view.

2. All true erysipelas, according to Trousseau, is traumatic; that is to say, it never develops itself otherwise than in dependence upon a previously existing open wound or solution of continuity, not necessarily a large one; it may be only a slight excoriation, nay, a lesion so small that the person himself may hardly be aware of it. Moreover, in regard to facial erysipelas, such lesion, when not present on the external integument, may frequently be found in the mucous lining of the mouth or nares. It constitutes, in fact, the primary spot of infection, and the starting-point of the inflammatory process. Most subsequent writers have adopted these views of Trousseau's, and they seem generally to be in accord with clinical experience. The failure of the disease to spread, then, in hospital wards, families, etc., might be in great measure due to the absence of this essential condition of receptivity.

3. Immunity from liability to attack, that is, under all circumstances, probably does not obtain to any appreciable degree. As in the case of small-pox, there may be a few very exceptional individuals originally insusceptible of the disease; but, notwithstanding the frequent denial of immunity acquired by a previous attack, evidence is forthcoming to show that protection within certain limits is conferred thereby.

4. As is only a familiar truism, from superficial resemblances, which may be very close, diseased conditions are apt to be confounded together which yet are fundamentally distinct.

In connection with this last point, Dr. Goodridge relates some personal experiences of his own, by which he is led to the conclusion that in cases of facial erysipelas, as they ordinarily present themselves in practice, whatever secondary varieties may exist, there are primarily two distinct forms to be dealt with—viz., the infective and the non-infective forms, or, as the distinction may otherwise be expressed, true, genuine erysipelas and spurious or pseudo-erysipelas. Jonathan Hutchinson clearly recognizes their existence when he says: "Those forms of erysipelas which are due to local irritation are, I think, almost always mild. It is when the disease is due to contagion that it assumes its greatest severity." If, then, in any given number of cases of ordinary facial erysipelas there be a more or less considerable proportion of cases of the non-infective form, a further step is gained toward the better understanding of those otherwise startling facts which at the outset seemed at once to bar the possibility of erysipelas being contagious.

Dr. Goodridge goes on to mention, also coming within the sphere of his observation, that of seventy-five cases of erysipelas of the head and face treated in the medical wards of the Bath Hospital during the twenty years ending December 31, 1882, there were nine (or twelve per cent.) furnished by the nurses and assistant nurses of the institution. "Probably," he adds, "there are few practitioners of experience, particularly if on the medical or surgical staffs of hospitals, who could not produce from their own practice similar evidence." If the literature of the subject be searched, there will be found no lack of instances of the same kind. But the most important evidence of all is that supplied by histological research and experimental pathology—that is to say, the evidence of a *contagium vivum*. This has recently been obtained through the investigations of Fehleisen, of Berlin—undertaken with the object of determining (1) whether in erysipelas a species of bacteria peculiar to it is regularly demonstrable, and, (2) if this be so, whether this micro-organism stands in any etiological relation thereto. For the first purpose, Fehleisen excised a small piece of

skin from the diseased part in each of eleven patients suffering from erysipelas, and in each one of the eleven found the lymphatic vessels of the skin, as well as those of the subcutaneous adipose tissue, and especially those of the most superficial layer of the corium, filled with micrococci arranged in chains. The micrococcus was identical with one already figured by Koch. To demonstrate that this was a specific organism, and that its presence was not merely accidental, Fehleisen next attempted to cultivate it outside the body. After frequent failures, he at length succeeded so far that, in the course of two months, he produced fourteen generations. Fehleisen had found somewhat similar organisms in the pus of wounds, in pyæmia, and in phlegmonous abscesses, but these never behaved in the same manner as regards the pure cultivation in gelatin. The mode of growth, then, of the micrococcus of erysipelas was found to be characteristic. The question remained, Could it, when inoculated into healthy individuals, produce genuine erysipelas? Experiments were first made upon rabbits. Nine were inoculated on the tip of the ear with the pure and cultivated micro-organisms. One of the animals showed an immunity, but in the eight others a typical erysipelas was developed. The disease took from six to eight days to run its course, and ended in recovery.

Lastly, and here culminates the interest of Fehleisen's work, he performed inoculations of the pure and cultivated micrococci on the human subject. After a period of incubation varying from fifteen to sixty hours, the characteristic phenomena were developed with greater or less distinctness in each one of the six individuals experimented on—leaving no room for doubt that their inoculation with Fehleisen's cultivated micrococci had for its result the production, or rather the reproduction, of a genuine erysipelas.

Assuming the correctness of these researches, the proof of the contagiousness of erysipelas would seem to be complete; the specific nature of the contagium and its etiological relation to the disease are both alike demonstrated. But, at the same time that the transmissibility of the disease from man to man by direct contact is thus shown, it is to be observed that this is not the only mode of contagion. There is good reason to believe that, besides *within* the human or animal body, the erysipelas-cocci propagate themselves *outside* of it, and may be diffused in swarms through the air. Hence, in those not uncommon instances where in the causation of the disease *immediate* contact can not be traced, *mediate* contact or aerial infection may justifiably be inferred. And, this being so, it follows that the doctrine of the spontaneous generation of erysipelas, which still finds favor with some authorities, can have no *locus standi*. As of other diseases of parasitic origin, it must be said of this disease that it is perpetuated solely in obedience to the law of continuous succession. Further experiments by Fehleisen clearly prove that a certain immunity is acquired by a previous attack, and the question of the distinction of erysipelas from other zymotic diseases on this ground resolves itself into a mere question of degree.

FATTY DEGENERATION OF THE HEART.—The "Lancet" (February 16, 1884), commenting on the death of Cetewayo, which is supposed to have been due to "fatty degeneration" of the heart, says the medical evidence is not conclusive, but it is a fair presumption that death may have been caused as suggested. This conclusion must not, however, be hastily drawn from the fact that Cetewayo was a prodigious feeder. The popular error that "fatty degeneration" of the heart is the same thing as an accumulation of fat around that organ is one which ought to be corrected, as every practitioner, of course, knows how to correct it. When muscular tissue degenerates, as it may do from any one of many morbid causes, fat is deposited interstitially in the place of the atrophied organic structure. As a matter of physiological or pathological fact, "fatty degeneration" is quite as likely to occur in a thin subject as in one that is obese, and voracious feeding has nothing to do with "fatty degeneration," though in a certain proportion of instances it may have something to do with the accumulation of deposits of fat around organs and in the interspaces of muscle fasciculi. We ought to keep the discrimination of matters which are likely to be confounded always clear. Many conditions besides large eating determine the presence of fat, and "fatty degeneration" is, as we have said, something altogether apart from, and in no way to be confounded with, fatness.

Original Communications.

THE TREATMENT OF DIPHTHERIA AND CROUP

BY LARGE DOSES OF BICHLORIDE OF MERCURY.*

BY WILLIAM M. THALLON, M. D.,

BROOKLYN, N. Y.

MR. PRESIDENT AND GENTLEMEN: It is within the last few years only that the treatment of diphtheria and croup by means of large doses of the bichloride of mercury has been brought forward in therapeutics. I do not know exactly who was the originator of the method in question, but it is often called "Pepper's treatment," from the fact that Professor Pepper, of Philadelphia, has warmly indorsed it. I believe he ascribes the originating of the plan to a practitioner of Pittsburg, or its immediate vicinity, but I do not know this gentleman's name.

The way my own attention was led to the matter was thus: Some years ago, in reading in Schmidt's "Jahrbücher" an account of Robert Koch's experiments on germicides, I was very much struck with the extraordinary antiseptic properties of bichloride of mercury. Shortly afterward I read an interesting paper by Wood and Formad, of Philadelphia, on the existence of certain specific bacteria in the blood and the exudate of diphtheria, and their experiments in inoculating healthy animals with the disease.

Combining the thoughts suggested by these two different sets of experiments, I made some calculations then as to the quantity of mercuric bichloride that would be required to sterilize the blood, and to these I will refer again later on.

The matter rested thus in my own mind until, in talking with my friend Professor Armor on this point, he told me that he had recently heard of some cases in the practice of Professor Pepper where this line of treatment had been successfully carried into effect. From this I was led to try the remedy, and I shall presently give you all the clinical evidence I have on the subject. I appreciate very well that this method of treatment is to be judged entirely by clinical results. If these prove bad, no pathological theory of its action, or belief in its germicidal virtues, will be of the least compensation. But, in order to give the method a fair trial, there are certain points that must be observed. In the first place, the treatment consists in large and frequently repeated doses of corrosive sublimate—the bichloride of mercury. I wish to insist at the outset that this is an entirely different thing from the treatment of the disease by the mild chloride of mercury—calomel. Some years ago Dr. Corbin read an interesting paper on the Calomel Treatment before this society. Other salts of mercury have had their enthusiastic advocates, but the bichloride is an entirely different thing—it is different in its chemical affinities, in its physical properties, especially its solubility,

and, above all, in its physiological relations, especially its absorptibility. Therefore, the bichloride treatment must stand or fall on its own merits.

The drug has been used in two ways in the treatment of diphtheria:

1. As a local application, either in the form of a spray or wash to the diseased parts.
2. As a constitutional remedy.

It has been used only in this second manner in all the cases that I will report this evening. I must confess that I am somewhat skeptical as to the value of local treatment in diphtheria. At most I am inclined to use locally only such means as are sedative to the inflamed parts—such as ice.

I do not think it is practicable to destroy the organisms which are undoubtedly present in the foul-smelling membrane of diphtheria by a sufficiently strong wash of bichloride of mercury without exciting an amount of irritation, which far more than counterbalances the possible good.

Besides, our throat applications are only on the surface; they don't reach deep enough. While it is more than probable that the entrance of the diphtheritic poison is effected through the throat, long before we recognize the disease by its characteristic exudate, a constitutional infection has occurred.

The disease kills, not by its local but by its constitutional effects. The only exception that can be taken to this statement is in cases of membranous croup in children, and here a truly antiseptic application to the larynx is entirely out of the question. I make these statements with some diffidence and simply in explanation of my practice. Should further evidence and the testimony of reliable observers convince me of the value of bichloride of mercury as a local application in these cases, I shall gladly adopt it. But until I experience such a change of heart I shall continue to use as local remedies in diphtheria those agents which are soothing and not irritant to the parts, and which conduce to the comfort and not the discomfort of the patient. It is therefore purely as a constitutional remedy that I have used the bichloride of mercury in these diseases, and it is on its value in this domain that I shall base any claims for it I may subsequently make.

With regard to its mode of administration, the first point is that it should be given largely diluted with water. I think this should be invariably insisted on, because thereby you avoid the possible danger of irritating the mucous membrane of the stomach. I had one case—not of the diseases under consideration—in which I believe emesis was provoked chiefly because the mother gave the bichloride undiluted, contrary to orders. When thus freely diluted, I have never seen any irritant effects produced by its use—either on the gastric or intestinal mucous membranes. In none of my cases has vomiting or purging occurred. I think you will admit before I get through that these cases show a remarkable tolerance of the drug quite out of all proportion to what we should expect judging from the standard of health.

With reference to how long these large doses of the bichloride should be used, I should say as short a time as

* Read before the Medical Society of the County of Kings, March 18, 1884.

necessary. And the criterion which I have mainly followed is the state of the false membrane. If this is increasing, I increase the drug; if it is stationary, I maintain the same dose; if it is decreasing, I diminish the remedy; and, if the membrane has disappeared, I at once stop the bichloride.

I have found it convenient to have two standard formulas, according as I wish to combine iron with the mercury or not. I generally write for a three-ounce mixture, with half a grain of the bichloride, so that each teaspoonful contains about one fortieth of a grain. The following are my prescription models:

FORMULA I.

- R Hydrargyr. bichlor., gr. ss.;
Tinct. ferri chlor., f ʒ iij;
Glycerin., f ʒ ss.;
Aqua, q. s. ad f ʒ iij.
M. Sig. f ʒ j, as directed, in water.

FORMULA II.

- R Hydrargyr. bichlor., gr. ss.;
Vin. pepsin.,
Elixir bismuthi, aa ʒ jss.
M. Sig. f ʒ j, as directed, in water.

The second formula is the pleasantest way of prescribing the remedy, and it is the one used by Dr. Pepper, as Dr. Armor informs me.

Practically, I now generally begin with the second formula, and, when convalescence has commenced, I resort to No. 1 to get the benefit of the iron.

CASE I. DIPHTHERIA.—Tillie R., aged eighteen, born in the United States, unmarried, residence on western slope of Prospect Park, weight about one hundred pounds. I was first called to see the patient on July 28, 1883.

Found a thin, anæmic girl, who complained that she couldn't swallow, that she had been feeling poorly for a week or more, but had got much worse during the last twenty-four hours. She thought she had "quinsy sore throat," as she had suffered from that trouble before, and with this in mind she had been poulticing her neck. Her four sisters had all complained of sore throat, etc., during the last few weeks, and they all looked pale and anæmic. Patient complained of pain in back and head, especially at night; darting pains in right ear and submaxillary region.

Examination.—Temperature, 103.75° F. Pulse, over 110. Respirations slightly quickened. On looking into the throat, the whole of the pharynx was found covered with a dirty, grayish membrane, foul smelling and tenaciously adherent; it was very sharply limited on the soft palate, where an abrupt ragged line of deep red contrasted with the pale mucous membrane in front. Two patches of membrane in different stages of formation—one about the size of a one-cent piece, the other of a two-cent piece—were observed on the soft palate. Bowels costive and tongue thickly coated. Voice hoarse and nasal, breathing through mouth. Could not open her mouth wide because of the pain it gave.

On investigating the sewerage I found a stationary basin and overflow pipe in the room, and these communicated directly, without any intervening trap, with the sewer-pipe, just in front of where the soil-pipe from the water-closet emptied into it. In this way there was free regurgitation of sewer-gas, etc., into the sleeping apartment.—Diagnosis, diphtheria.

I at once ordered the patient to be moved into a large, well-ventilated room, and had the plumbing put to rights. The patient was put upon the first formula, getting $\frac{1}{16}$ gr. of the bichloride every three hours. In addition, a cathartic that night of calomel, gr. v, and co. jalap powder, gr. x.

In the way of food, as much milk and beef-tea as she would take, and three milk punches daily. Also small pieces of ice.

Next day, July 29th.—I saw her in the morning: the bowels had moved freely, and she had taken a pint of milk and two cups of beef-tea. Complains greatly of throat. Says the medicine hurts, so I ordered it to be freely diluted. Has coughed up a great deal of mucus and some membrane. The two smaller pieces of membrane on the palate were not visible.

They sent down that night, as she was in great pain, so I ordered the bichloride to be increased to once in every two hours; and, in addition, gave some liq. opii co., \mathfrak{v} iij, and sod. salicyl., gr. v, every two hours till relieved.

Next morning, 30th.—The temperature was 101.5°. Pulse, 100. Had slept some from the opium, but this morning it had made her vomit twice, and she had, in throwing up, dislodged some membrane, one piece as long as the middle finger, which had greatly relieved her. Had taken more nourishment. Continued bichloride as before, also the opium if needed; and, instead of the sodium salicylate, ten grains of quinine at noon.

31st.—Temperature, 103°. Pulse, 90. Felt more comfortable, and throat better; has had so much distress at times in coughing up membrane that she has used hot water to make her vomit; has raised much mucus. More nourishment taken. Increased the bichloride to $\frac{1}{8}$ gr. every two hours. Otherwise the same.

August 1st.—Temperature, 101.75°. Pulse, 95. Great deal better; more nourishment taken; quinine makes her head ache, so diminished to six grains. Diminished bichloride to $\frac{1}{8}$ gr. every four hours. As her bowels had not moved freely, gave a laxative.

2d.—Temperature, 101.25°. Pulse, 90. Improving rapidly. Throat much better; can swallow without pain; voice is more natural; coughs up less; can not see any membrane to-day. Eats with relish, and a good deal.

3d.—Pulse, 90. Temperature, 101.5°. Same treatment.

4th.—Pulse, 95. Temperature, 101°. Throat looking well, sleeping and eating well; diminished bichloride to $\frac{1}{16}$ gr. every four hours.

6th.—Temperature, 101.25°. Pulse, 90. Not so well yesterday; complained much of aching in bones and in neck (cervical lymphatic glands). Throat looks very well; diminished the bichloride to $\frac{1}{16}$ gr. three times a day. Stopped the quinine.

8th.—Temperature, 99.5°. Pulse, 82. Steady progress; sitting up. Throat still somewhat injected, but more normal. Sleeps and eats well. Bowels regulated by pulv. glycyrrhizæ co. Bichloride same— $\frac{1}{16}$ gr. t. i. d.

12th.—Temperature, 99.5°. Pulse, 80. Improving; more strength; throat about same. Substituted bitter tonic.

September 1st.—Is quite well; eats and sleeps well, and is gaining flesh rapidly; has gained ten pounds in two weeks, and has more flesh and blood than at any time in last year.

Note six months later.—Patient has had none of the sequelæ of disease, but has continued in good health. This patient took altogether, in fourteen days, about $3\frac{1}{2}$ grains of the bichloride of mercury, and during four days, when she was on the largest doses, nearly two grains.

CASE II. MEMBRANOUS CROUP.—Areta P., aged four years, born in United States. Weight about forty pounds. On Wednesday, February 13th, I was called in the evening to see the little patient. Dr. Skene had seen her two days previously, and had prescribed a mixture containing sedative doses of

quinine, as she was suffering from fever. She had been ailing for two weeks, complaining of general malaise and headache, and the child was languid and pale, and without much appetite. The throat symptoms had all developed in the twenty-four hours previous to my first visit. Her pulse was 140, her temperature 102.5° . She had some cough, and her voice was hoarse and thick. Her mother stated that she had been having paroxysms of coughing and choking, especially on waking up. On listening to her chest, I found no signs of trouble there. Her skin was hot and dry, her tongue heavily coated. On examining her throat with the light reflected from a laryngeal head-mirror, the soft palate and upper portion of the tonsils appeared of a dirty, anæmic color. Below this, on the posterior wall of the pharynx and reaching forward to the tonsils, was an abruptly limited zone, deeply injected and of a bluish-red tint. So abrupt was the line of demarkation between the inflamed and the non-inflamed areas of mucous membrane that it looked as if a caustic had made it.—Diagnosis, membranous croup.

Treatment.—I at once ordered solution No. 1, giving $\frac{1}{16}$ of a grain of the bichloride, with the addition of two drops of liq. opii comp., to be repeated every three hours. In addition, the quinine was kept up and lime was slacked in the room. The next day (Thursday) Dr. Skene and I both saw the child, but no change was made in treatment. The temperature fell about half a degree, but the laryngeal symptoms increased, as there were more frequent and distressing paroxysms of coughing and complete loss of voice. The father of the child, who was in Cuba, was telegraphed for. The next morning (Friday, 15th) Dr. Armor saw the child in consultation, and agreed that it would be well to increase the dose of bichloride and omit the other ingredients. She was therefore put on the use of solution No. 2, getting $\frac{1}{16}$ of a grain of the bichloride every hour and a half. A spray of chloride of ammonium was kept up by means of a croup-kettle, and the slacked lime was discontinued. Sulphurous-acid fumes were tried for a short time, but were so disagreeable to the mother that they were discontinued. The only other medicine used was paregoric in five-drop doses, to quiet restlessness. The quinine was stopped, as the temperature diminished about half a degree each day; the pulse was about 110; her bowels moved freely, and her general condition was more comfortable. She took a fair amount of nourishment—milk, milk punch, beef-juice, and ice.

But the throat symptoms remained so threatening that I stayed with the child all that night (Friday), with a tracheotomy tube in my pocket, and prepared to operate if her breathing became more obstructed. Next day she was a little easier, and, when Dr. Skene was there in the morning, she coughed up a piece of membrane from the larynx, which he examined and described to me as of a leather-like consistence, one eighth of an inch thick, half an inch wide, and three quarters of an inch long, and as perfect a specimen of true diphtheritic membrane as he had ever seen; there were also several smaller pieces expelled in detached fragments which would make up about as much more as the large piece. From this point on the improvement was steady. The bichloride was discontinued on Tuesday, the voice having been largely regained.

The child's further convalescence was uneventful and steady, and she took first a bitter and then an iron tonic. She was considered quite well one week after the discontinuance of the bichloride, and up to the present moment has remained so—no evil sequelæ of the disease having shown themselves.

During the five days and a half—130 hours—that she was taking the bichloride she had taken in all a little over two grains, the mother's idea of a teaspoonful being more liberal than a drachm, and during one period of twenty-four hours the child took over half a grain of the drug.

CASE III. DIPHTHERITIC PHARYNGITIS.—During the convalescence of the preceding patient, just eight days after the subsidence of the acute symptoms, the brother of the patient, a boy of about nine years, suddenly developed throat symptoms. He was seen on Tuesday by Dr. Skene, and then had a well-marked diphtheritic exudate on both tonsils. He was at once put on the bichloride of mercury, $\frac{1}{16}$ grain every hour and a half (formula No. 2), and nothing else was given. The next day I saw him and the membrane was almost entirely gone, and on the following day not a trace of it could be seen. His further recovery was uneventful and steady.

This case is of interest from its close relationship to the preceding, and would seem to show the identity of the poison producing the membrane of membranous croup and the membrane which we call diphtheritic on the tonsils or pharynx. It is most interesting in showing how promptly this case yielded when put on large doses of bichloride of mercury at the very beginning of the attack. He took altogether about three quarters of a grain of the bichloride, nearly one half a grain being taken in the first twenty-four hours.

CASES IV, V, and VI. TONSILLITIS WITH DIPHTHERITIC EXUDATE.—For the facts in the following three cases I am indebted to Dr. Skene. All three patients were inmates of the same household. I need not give the details of the cases very fully, except inasmuch as they illustrate one point.

The daughter, aged about eighteen years, and the maid-servant, aged about twenty-four years, each had a violent chill followed by fever, headache, coated tongue, etc., in the afternoon of the same day. When seen by the doctor the following morning, each had a well-marked pharyngitis and tonsillitis, and considerable diphtheritic exudate on the soft palate and tonsils; this was about the same in extent in the two cases. Both patients were put on the bichloride treatment (formula No. 2) in the same doses, gr. $\frac{1}{16}$ to the teaspoonful, the same mixture, and both were told to take a teaspoonful throughout the day and following night. At night-time the daughter slept alone in her room, and did not take her medicine, and thus missed four or five doses. The servant, on the other hand, had a companion stay with her (another servant), who administered the medicine regularly throughout the night, so that this patient did not miss a single dose. The next morning, when the doctor saw them, the daughter, who had not taken the bichloride regularly, still had the diphtheritic exudate in her throat, but little if any diminished in extent from yesterday, while the servant, who had taken her medicine regularly, had scarcely a trace of the membrane left. Both subsequently recovered, but the servant was well first.

The above-mentioned two cases seem to me to furnish a most admirable test of the value of this treatment, and they go to prove that a certain amount of the drug—far in excess of a tonic dose—has to be given to produce its characteristic effects in diphtheria.

The third case in the family occurred about a week subsequently in the person of the lady of the house.

The trouble began, as the others did, with a chill and fever, followed next day by the appearance of the exudate on the pharynx and tonsils, the membrane being much more marked in thickness and extent than in the preceding cases.

She was put on the bichloride of mercury (formula No. 2), getting $\frac{1}{16}$ of a grain every hour from the start, and the exudate rapidly melted away as in the other two cases and the patient made an uninterrupted recovery.

These three cases, all occurring in the same house, led to a careful investigation of how the trouble got into the family. The plumbing seemed to be in perfect order when inspected, and the hygienic surroundings of the family were of the best. The only other person who was affected was the man who came in to attend to the furnaces—from outside. Whether he brought the disease with him I don't know, but it would seem probable, for the order in which the patients were attacked was, first the furnace man, then the servant, then the daughter, lastly the lady of the house.

The total amount of bichloride taken in these cases can not be determined exactly, but in the first twenty-four hours in each case it was as follows: The servant, one fourth grain; the daughter, about one seventh grain; the mother, one half grain.

CASE VII. DIPHTHERITIC CROUP.—I was called on February 10, 1884, to see Edith T., aged four years and a half, born in the United States. She had had a violent chill early in the morning, and when I saw her, in the afternoon, her temperature was $103\frac{1}{2}^{\circ}$, her pulse about 130. Her skin was hot and dry, her tongue was thickly coated, and she complained of intense headache and pain on swallowing. She had been a little out of sorts for a day or two, her mother said, but nothing to alarm them. Her voice had become husky within the last twenty-four hours. On looking into her throat, the upper portion, including the whole soft palate, upper part of tonsils, and upper portion of pharynx, was of a pale and anæmic color, while below a well-marked line of demarcation it was a bluish-red. This inflamed part had a slightly glistening appearance, that strongly suggested to my mind the slippery pouring out of plastic exudate.

I at once ordered formula No. 1, giving $\frac{1}{16}$ gr. of bichloride every two hours, also the next morning six grains of quinine in solution. If the bowels did not move before night, an oil enema was to be given. I saw the case the next day, when the temperature was below 102° and the pulse about 110. The bowels had moved without the enema. Headache and soreness of the throat decidedly less, though the appearance of the throat was about the same. Diminished the quinine one half, but continued bichloride same. The next day the child was better, so I discontinued the quinine altogether; diminished the bichloride one half.

The following day, being the fourth from the day of invasion, she was so much better that I diminished the bichloride to a minute dose— $\frac{1}{32}$ gr.—three times a day, in conjunction with an iron tonic, and from this point she steadily progressed, and was taken to the country, a distance of some hundreds of miles, on the eighth day. She took altogether about three quarters of a grain of bichloride, of which five eighths was given within the first seventy-two hours—one-half grain in the first forty-eight hours.

I was quite unable to trace any cause for the attack in this case. It may seem unwarranted to make a diagnosis of diphtheritic croup in this case when I did not see at any time any true membrane; but the whole aspect of the case suggested to my mind that the membrane would very speedily have been formed had it not been prevented by the free use of bichloride of mercury.

CASE VIII. FOLLICULAR TONSILLITIS WITH DIPHTHERITIC EXUDATE.—I am indebted to Dr. Skene for the particulars in the following case: A boy of fourteen years, attending school, came home in the afternoon feeling ill, and had a restless, feverish

night. When seen early next morning he had a temperature of 103° , pulse 110. Had headache and pain in all parts of the body, especially the back; his tongue was coated, and he was nauseated. His throat had the characteristic appearances of incipient diphtheria; his tonsils (which were hypertrophied) presented the usual appearance of follicular inflammation with well-defined diphtheritic exudate around a number of the larger follicles. He was put on the usual mixture (No. 2) of bichloride, and, when he had taken, in all, one half of a grain, which he did inside of forty-eight hours, his throat was well, barring a little hyperæmia. He was then put on a tonic of iron, and at the end of one week returned to school in better health than he had been before the attack.

CASE IX. DIPHTHERIA AND SCARLET FEVER (Dr. Skene).—“E. S., a delicate girl, seven years old, with the following family history: Six months before she was taken ill her father died of tuberculosis; during the child's illness her mother died of the same disease. The child had been very delicate all her life, and subject to occasional attacks of severe acute dyspepsia. She had hypertrophied tonsils and many other of the characteristics of the tubercular diathesis, to which she was hereditarily liable, as the family history shows. She was attacked in the night with very high fever and profuse vomiting, but was somewhat easier next morning. Her grandparents, with whom she lived, took it for granted that this was one of her ordinary attacks of acute dyspepsia, and did not send for the doctor till the afternoon of that day. When she was first seen she had a well-marked diphtheritic exudate on her right tonsil which extended from this over the arch of the palate and covered two thirds of the uvula. Her temperature was 104° , and the pulse so rapid it was not counted. She was still nauseated and restless, and complained bitterly of her throat and head. I put her on the bichloride of mercury, one fortieth of a grain in elixir of eucalyptus every hour—as that vehicle had formerly been agreeable to her. She took very little nourishment the first twenty-four hours, and was very nervous and restless during the night. When I saw her the next forenoon, the exudation on the right tonsil and uvula had not increased in thickness, but it had extended to the left tonsil and involved half of it. The temperature was still a fraction over 104° , and she was covered from head to foot with a copious eruption of scarlet fever.

“I was somewhat disconcerted with regard to my therapeutics, for, although I had confidence in bichloride of mercury in the treatment of diphtheria, I knew nothing of its effects in scarlet fever, and here I had the two diseases unmistakably combined, I had never seen in my past experience a child of such faulty organization recover from an attack of scarlet fever and diphtheria, especially when the diphtheritic exudation preceded the cutaneous eruption. It therefore appeared to me that I could hardly have a worse result with the bichloride than I had with all other methods. So I kept on with the bichloride of mercury, giving one fortieth of a grain only every two hours now. From the end of the second day after I saw her the exudate did not extend, but gradually diminished. She made a most excellent recovery from the scarlet fever, and had none of the bad sequelæ of either disease.

“It is now over a year since this occurred, and during that period she has been in better health than ever before, and to-day she possesses a better organization than she did prior to this attack.”

I wish to add the notes of one case of an allied, if not identical, condition in which I have used large doses of the bichloride of mercury. I allude to the sloughing sore throat of scarlet fever which follows the cutaneous eruption in that affection in certain cases. I am not prepared to

make any suggestions as to the possible pathological relations between the poisons of diphtheria and scarlet fever, which have been so much canvassed of late, especially in the English medical journals. But it will not be denied that there is a remarkable similarity in the rapid necrosis of tissue—with the foul smell and rapid sloughing—between the two conditions.

CASE X.—I was called one Saturday morning in the fall to see Andrew G., a child of two years of age. The room I found him in was in a damp basement in a house on Butler Street, near Court Street. When I saw him he had a well-marked eruption of scarlet fever, which had appeared the day before; but the mother was mainly alarmed about his throat. On looking into this, it seemed to me as if the whole soft palate and tonsils were one mass of sloughing tissue. It could be easily scraped off, and then bleeding occurred. His temperature was 103° and a fraction, his tongue heavily coated, and the child restless and refusing to take any nourishment. I told the mother to grease him with fresh lard, to allay the cutaneous discomfort, and prescribed formula 1, giving him $\frac{1}{4}$ grain of bichloride every three hours. The next day he was worse, and the mother said it was impossible to give him that medicine, it made him vomit so, so he had only had one dose. I was unwilling to abandon the bichloride, so I wrote for it alone in water, and instructed the mother to give it freely diluted with water—a teaspoonful containing $\frac{1}{4}$ grain every three hours. On the following day the slough was very much less, and the smell was nothing like so foul as before. The following day an even hyperæmic redness was all that could be seen, and the child made an unbrokenly good recovery. What threatened to be a severe, if not fatal, attack of scarlet fever ran a mild course. The child has had no bad sequelæ that I know of.

The total amount of bichloride this child took was about half a grain, and all within three days. I think this result is very remarkable, considering the extremely bad hygienic surroundings.

(To be concluded.)

MEMORIAL SKETCH OF THE LIFE

OF

J. MARION SIMS, M. D.*

By W. GILL WYLIE, M. D.

MR. PRESIDENT AND GENTLEMEN: I am happy to say that Dr. J. Marion Sims has left an autobiography of several hundred pages, giving a full account of his life and work up to 1863; and that he left in manuscript a revised and more or less completed work on "The Surgical Diseases of Women," both of which are soon to be published. What I have to say to-night, up to the time when I first met Dr. Marion Sims in 1868, has been taken directly from the manuscript of his autobiography.

In his autobiography, after some preliminary remarks, he begins: "It is a trite saying, that 'every life is a poem, be it long or short.' Mine has been a real romance, full of incident, anxiety, hope, and care; some disappointments and many successes, with much sickness and sorrow; but it has also been full of joy, contentment, and real happiness.

"I was born in Lancaster County, S. C., January 25,

1813, about ten miles south of the village of Lancaster, a mile or more west of the old wagon road from Lancaster to Camden. The ancestors of my father, John Sims, were of the English colonists of Virginia. My mother, Mahala Mackay, was the daughter of Charles and Lydia Mackay, of Scotch-Irish origin. The family came to America about 1740." Lancaster at this time was a small village of about one thousand inhabitants, the county-seat of a farming district about twenty-five miles square. It was an out-of-the-way place, twenty-five miles from the nearest village. Dr. Sims says: "My father, feeling the want of an education himself, was determined to educate his children, and so he began with me at a very early age. He then kept a little store, about a mile north of Hanging-Rock Creek, on the road leading to Lancaster. This was in 1818. Mr. Blackburn, a Scotchman, had just opened a school in a log cabin in the old field very near the ford of this creek." It was here the doctor received his first lessons.

He relates a little incident that took place when he was about eight years old, which to me, knowing him as I did, is very significant. He was asked by an old friend of his father's to give the proper name of a certain weed. His answer caused the old gentleman to say: "I would advise you hereafter, and lay it up in your memory, as long as you live, never to presume to express an opinion on any subject unless you are informed on that subject."

The doctor says: "I was never so mortified in all the days of my life. I was exceedingly mortified, and I am sure that I have thought of Mr. Patterson a thousand times since then. When I have been called upon to give an opinion and didn't feel competent to give it, I have profited by the advice he then gave me." Of this I am certain, for Dr. Sims was very non-committal on all doubtful points, but was very definite, clear, and firm about what he did know. In 1825, when twelve years old, he went to Lancaster village, where his father had moved the previous year, and this same year the Franklin Academy was inaugurated at Lancaster; he attended school here for five years, and it was here that he met Theresa Jones. He became sincerely attached to her, and, long before they were engaged, she was a great influence in his life, and, together with his mother, who was a sincere, good woman and devoted mother, had much to do in establishing his good habits, noble sentiments, and high moral character. He was not noted at school, but was known as a bright, genial fellow.

In 1830 he entered the South Carolina College at Columbia, S. C. He says: "When I went there I was one of the best boys in the world. I do not know that I had a single bad habit. I didn't swear, I didn't drink, I didn't gamble; indeed, I had no vice that could be called a vice. I was such a good boy that my mother certainly expected me to be a Presbyterian clergyman." Having entered as a Junior, he graduated from South Carolina College in December, 1832. He says of himself: "I never was remarkable for anything while I was in college except good behavior. Nobody ever expected anything of me, and I never expected anything of myself. I felt really sorry that the time was drawing near when I would have to assume the stern duties and responsibilities of real life and of man-

* Read before the Medical Society of the County of New York January 28, 1884.

hood." At this time he was desperately in love, but was too poor to marry, and did not care to take up a profession. His father wished him to study law, but they finally agreed on medicine, and, when twenty years old, he began to read medicine under Dr. Churchill Jones. He remained with Dr. Jones for a year. Dr. Jones was a good surgeon, and it was here that Dr. Sims imbibed a desire to distinguish himself in surgery.

In November, 1833, he left for Charleston, S. C., to attend medical lectures at the Charleston Medical College. He was by no means precocious; at this time he was a beardless youth of twenty, and he says of himself: "I had failed in my duty as a student in my college course at Columbia; I was now determined to reform my methods. I had to prepare for a period that I had looked forward to not with pleasurable anticipation, but with dread. Most of the young men whom I had associated with all my life had looked forward to manhood with joy and satisfaction, but with me it was exactly the reverse. I was afraid to be a man; I was afraid to assume its responsibilities, and thought that I did not have sense enough to go out into the rough world to make a living as other men had to do. I was small in stature, and I did not feel that I had intelligence enough to grapple with or to pit myself against such opposition as I should encounter in life. So when I went to Charleston I went to work in real earnest." He remained in Charleston till spring.

October 1, 1834, he left home for Philadelphia, to attend lectures at the Jefferson Medical College. Here, as in Charleston, he devoted himself to his work, but did not distinguish himself in any way. In both places he boarded with families in which there were refined young ladies, and did not lead a wild life as a medical student. He graduated at the Jefferson Medical College at Philadelphia on the 1st of March, 1835. He says at this time: "I felt absolutely incompetent to assume the duties of a practitioner. . . . When I graduated, I presume I could have gone into the dissecting-room and cut down upon any artery and put a ligature around it, but I knew nothing at all about the practice of medicine. I had had no clinical advantages, no hospital experience, and had seen nothing of sickness."

He went home in May, 1835, his father rented him an office, and he began the practice of medicine, in Lancaster village. After waiting about two weeks he had his first patient—a case of cholera infantum. The child died. In two weeks after this he was called a second time, and again to a child with cholera infantum. He made up his mind that if this child died he would quit the town; and when it did die, a few days later, he took down his sign and prepared to go West. He was disgusted with medicine, and, if he had had money, he would never have given another dose. He says: "On the 13th of October, 1835—and the thirteenth, by the way, has always been a lucky day with me; and so has Friday; I was born on Friday . . .—I started for Alabama."

By chance he met some people that he knew, and he settled down in Mount Meigs, a small cross-roads place about twenty miles from Montgomery, Ala. He bought out one of the two doctors in this place and began practice. His

first case of importance was one that had been seen by seven or eight doctors from all sections, but was not helped by any of them. Dr. Sims diagnosed abdominal abscess, was bold enough to open it and let out the pus, and the man recovered. In a year's time he had a good country practice. In September, 1836, he was dangerously ill with malarial fever. The doctor wished to bleed him, but he would not let him, for he did not believe in it. This was his first serious illness. He never bled, and gave but little medicine.

Dr. Sims was married, on the 21st of December, 1836, to Miss Theresa Jones. In January, 1837, with his wife, he returned to Mount Meigs, and had a fair country practice. In 1838, Dr. Blakey, living about ten miles distant, in Macon County, offered Dr. Sims a partnership in a large practice among rich plantations. He accepted the offer, bought a little land and put up a double log cabin, and soon had a good practice. The first two of his children were born in this cabin. At this time he says of himself: "I am an example of a man who has never attained the ambition of his early life. My successes have been in a direction that I never dreamed of when I started. I felt no particular interest in my profession at the beginning of it apart from making a living; I worked at it earnestly, and at the end of five years I had become quite a respectable physician, and, I can truly say, quite a successful one. Still, I was really ready at any time and at any moment to take up anything that offered, or that held out any inducement of fortune, because I knew that I could never make a fortune out of the practice of medicine. I, of course, never dreamed of anything more than a living and a local reputation."

About this time he agreed to quit medicine and go into a clothing house, but the scheme fell through, and he kept at his practice. In 1839 he had as much as he could attend to.

In July, 1840, he nearly died of congestive chills, and determined to move to a more wholesome neighborhood.

On the 13th day of December, 1840, he moved to Montgomery.

He says: "The year 1840 was a memorable era in my life, and seemed to be a turning-point in my career. For the first five years of my professional life, 1835 to 1840, I was willing to turn aside to do anything to make money. But when I went to Montgomery I gave away my dog, sold my gun, and I have never loaded or fired a gun since. I devoted myself to my profession, determining to succeed, if industry and application could command success. I had an ambition for surgery—general surgery—and I was performing all sorts of beautiful and brilliant operations. This was before the days of anesthetics. I had made, in five or six years—1840 to 1845—such a reputation for surgery that people came to me from all parts of the State."

His first article for publication was the report of a case of hare-lip in the "Baltimore Dental Journal" in 1845, and in the same year, shortly after this, he wrote his celebrated essay on "Trismus Nascentium."

In June, 1845, he was called to see a case of instrumental labor which resulted in producing a large vesicovaginal fistula. Before this time he had had nothing to do

with diseases peculiar to women. He looked up the literature, and found that vesico-vaginal fistula was considered incurable; he had never before seen a case. "Strange to say," a month later another case was sent to him, and again, just one month later, a third vesico-vaginal case was sent from the country. He gave the patient a bed in his little hospital in his back yard, which he used for his negro surgical cases, and, of course, continued to read and think about the subject. He had been doing many operations in cases which before in that country were considered incurable, and here were three cases that seemed everywhere to be regarded as incurable. His success in other cases encouraged him to keep his mind on the subject. Just at this time, while one of these three patients was in his hospital, he was called to see a woman who had been thrown from a pony. She fell on her pelvis and retroverted her uterus. He put her in the knee-chest position, and, in replacing the uterus, the vagina was distended by air entering it. Comprehending what had taken place, he at once saw how he might be able to operate in a case of vesico-vaginal fistula. He started directly for home to try his experiment, stopped on his way to get a large spoon, bent it so as to retract the perinæum, and then went at once to his hospital and examined the case of vesico-vaginal fistula. He wrote at once for the other two patients with vesico-vaginal fistulae, and commenced to devise instruments with which to close the fistula. He succeeded in finding six or seven women with vesico-vaginal fistulae. He enlarged his little hospital by adding a second story, and then began the famous experiments.

Notwithstanding repeated failures during four years' time, he kept his six patients and operated until he tired out his doctor assistants, and finally had to rely upon his patients to assist him to operate. After four years he had perfected most of his instruments, and could succeed in partially closing the fistulae, but never in completely closing them. When his mind was full of the subject he came across a piece of small brass wire, and this suggested silver wire, and at once he went to a jeweler's and had some small wire made of pure silver. In May or June, 1849, he used the silver wire as sutures, and succeeded perfectly in closing the first vesico-vaginal fistula, and in two weeks more he cured two more cases.

About six weeks after his first successful case he was taken sick with diarrhœa. His health utterly failed, and he went from place to place trying to get well. Finally, when he fully expected to die, he says: "While lying in bed, I wrote out the history of my operations for vesico-vaginal fistula for the press, and sent the article to Dr. Isaac Hays, the editor of the 'American Journal of the Medical Sciences.' It was published in January, 1852." He had been North to New York and Philadelphia in 1849, '50, and '52. He would get better, but never entirely well, and finally made up his mind to sell out and come to New York to live. In May, 1853, he came North. In September, 1853, he bought the house, No. 79 Madison Avenue, and, although very much reduced in strength and health, still suffering from diarrhœa, he went to work. He made the acquaintance of Dr. Mott, Dr. Francis, Dr. Buck, Dr. Watson, and others. One of the doctors had a case of lacerated perinæum, and asked Dr.

Sims to show him how to repair it. This he did successfully. Subsequently the same doctor asked the loan of Dr. Sims's instruments to use in the New York Hospital, but did not invite Dr. Sims to assist or to see the operation. Dr. Valentine Mott gave Dr. Sims his first case of vesico-vaginal fistula in New York; this he cured, and soon the leading men were operating upon lacerated perinæums and fistulae, but Dr. Sims was left out. Dr. Sims saw that he must have a hospital for his work. Dr. Francis was always true to Dr. Sims, and could be relied upon; but the leading clique were against him, and he could do nothing through them or through any one that they could control. Dr. Stevens had been carried away by Dr. Sims's enthusiasm, and had promised to give him a chance to bring his plans before the profession; but afterward he said: "I have been talking with my friends in the medical profession, and I find here such a degree of universal opposition to you and to your enterprise that, I am sorry to say, I can not now give you the privilege or opportunity of addressing the profession under my auspices." Such opposition as this, together with threatened want, would have driven Dr. Sims from New York, but his wife would not consent to leaving, and her cool courage kept him here. By chance a friend brought Mr. Henri L. Stuart to see Dr. Sims, to advise him about establishing the Woman's Hospital. After hearing the doctor's story, Mr. Stuart said: "We will rent Stuyvesant Hall; we will advertise in the newspapers for the doctors to attend a meeting which is to be addressed by Dr. J. Marion Sims, late of Montgomery, Ala., on the necessity of a hospital in the city of New York for the treatment of the diseases of women. We will invite all the leading doctors in town by special cards, and they will come to hear you; and they will be wise enough to indorse what you have to say. If you tell your story to the crowd of doctors that I will get there as you have told it to me, we will carry the day." Mr. Stuart at that time was influential with the daily press of New York.

In May, 1854, the meeting was held, and it was by this means that Dr. Sims obtained the public indorsement of the medical profession which he could not get by direct appeals made to leading doctors. Dr. Sims selected for a committee Dr. Delafield, Dr. Mott, Dr. Stevens, Dr. Green, and Dr. French; and, subsequently, Mr. Peter Cooper and Mr. E. C. Benedict were put on the committee. Nothing else was done till fall; then Mr. Stuart said to Dr. Sims: "Now you have done with the doctors all that you can hope to do. You have their public indorsement, and they can not take it back. You have nothing to hope for from the doctors; your only chance is by appeal to the heads and hearts of intelligent women." The first woman that Dr. Sims succeeded in getting interested in his work was Mrs. Elisha Peck, now Mrs. Abernethy; through her he got at several others, but made little headway until he saw Mrs. Doremus. After hearing his story, she said: "Mrs. David Codwise must be first directress of this institution; Mrs. William B. Astor, second directress; Mrs. Ogden Hoffman, third; Mrs. Webster must be the secretary; and Mrs. Jacob Le Roy, treasurer.*

* Examination of the first reports shows that Mrs. Forlyce Barker was the first secretary.

On the 5th of February, 1855, Dr. Sims saw Mrs. Codwise and succeeded in interesting her. "On February 10, 1855, a meeting of the ladies was called at the house of Mrs. Codwise, and the Board of Lady Managers was organized precisely as Mrs. Doremus had said that it should be, and they at once appointed a committee to rent a building and open a hospital as soon as possible. A few days after this, Mrs. Doremus and Mrs. Codwise were called upon by prominent doctors, who endeavored to convince them that they were making a mistake, that they had been deceived, that no such hospital was needed," etc. But they failed in their mission. Dr. Sims says: "The Woman's Hospital, from the day that it was opened, had no friends among the leaders of the hospital men. I was called a quack and a humbug, and the hospital was pronounced a fraud. Still it went on with its work." The Woman's Hospital was inaugurated, at 83 Madison Avenue, on the first of May, 1855. Patients came in, and it soon proved a success. Dr. Sims says: "The hospital had been opened about six months when I told the Board of Lady Managers that I must have an assistant. They assented, and I selected Dr. F. U. Johnston, Jr.; but he had other plans. I then offered the place to Dr. George F. Shrady; he did not see fit to accept it." Soon after this Dr. Thomas Addis Emmet was appointed.

(To be concluded.)

A CASE OF ADENOMA OF THE RECTUM.*

By WILLIAM M. POLK, M. D.,

PROFESSOR OF OBSTETRICS AND THE DISEASES OF WOMEN AND CHILDREN IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK; SURGEON TO BELLEVUE HOSPITAL, DEPARTMENT OF DISEASES OF WOMEN.

THE patient was admitted to Ward 23, Bellevue Hospital, December 12, 1882, being then forty-four years old. Up to six years ago she had good health, and yet for some fifteen years she has had some pains in the back and groin, which seemed to have some connection with menstruation, as they were worse during the periods. Having no other uterine symptoms, she paid but little attention to the matter. She has had four children, all born easily, by natural labor. Careful inquiry and examination have failed to elicit any evidence of syphilis, either in her own case or in that of her parents; nor was there any evidence of cancerous inheritance. All her functions have been in the best state, especially menstruation, which, however, has ceased for some years. I now copy from the history as prepared by the house physician, Dr. Fruitnight:

The present ailment dates back six years. It showed itself first by losses of blood at stool, which she attributed to piles. She does not know of what color the blood was at first, but for the past fifteen months it has been dark, clotted, and more abundant. She has had pain in defecation for the past three years, lasting several hours. The pain has gradually grown worse, and for the past eighteen months it has been intolerable. It was burning and aching in character. For the last year and a

half she has been very costive, the bowels moving only after taking a cathartic. Occasionally she has ardor urinæ. For four months past she has scarcely been able to walk, on account of the pain.

On admission, she presents a sallow appearance, and is greatly emaciated; her appetite is poor, her bowels are constipated, and she complains of pain, dull and aching in character, in the back and thighs, and of burning pain in the rectum when defecating. She complains also of dizziness and of a sinking sensation in the epigastrium. She is in a wretched condition, mentally and physically. The lungs, the heart, and the abdominal viscera are normal.

Digital examination of the rectum shows a stricture about half an inch above the anus, extending up the gut about two inches. The stricture admits the index-finger with difficulty. It is due to a growth in the wall of the rectum, extending entirely around the gut. The vagina is not involved. Just above the stricture there is a small ulcer on the posterior wall of the rectum. The growth is very firm to the touch, and a rectal examination is very painful.

December 18th.—At the clinic to-day the patient was etherized, and the tumor was removed. An incision was first made from the anus backward to the coccyx; then, by means of the finger and the handle of a scalpel, the tumor, with the lower part of the rectum, was cut away from the external sphincter, an effort being made to save that structure, as it was not involved in the degeneration. Care was taken to secure all vessels with ligatures, and the enucleation was continued until the tumor was detached from the surrounding tissues, avoiding puncture of the vaginal wall. Then the rectum was ligated in sections just above the tumor, after which it was divided just below the ligature. The amount of blood lost did not exceed half an ounce. The rectum was drawn down and stitched to the sphincter ani in front and at the sides. The first incision made was not closed. A drainage-tube was introduced, and the wound was stuffed with borated cotton saturated with carbolic oil. The mass removed was about as large as a duck's egg, the thickest portion of the growth being situated laterally and posteriorly.

An unfortunate result of the operation was sloughing of that portion of the vaginal wall that lay next the tumor. The stitches attaching the cut edge of the rectum to the sphincter tore out, so that a recto-vaginal fistula was formed. With this exception, everything went well. The patient made so good a recovery that at the end of six weeks it was determined to make an attempt to close the fistula and restore the action of the sphincter. She was so impatient of delay that it was resolved to complete both operations at one sitting.

The state of affairs at this time was as follows: The opening in the vaginal wall was as large as a three-cent piece; the anterior edge of the remains of the rectum was united to the upper edge of this vaginal opening. The incision made to the coccyx had closed along its posterior third, and the large excavation in the ischio-rectal fosse made by the removal of the tumor had filled up to within three quarters of an inch of the surface. The rectum was not in immediate contact with the cut ends of the sphincter, as the stitches at this point had fared the same as those in the anterior margin.

The operation now performed was this: The edges and the lower or rectal surface of the fistula were pared, and the

* Related, with the exhibition of the patient, before the New York Obstetrical Society, June 5, 1883.

inner face of the upper portion of the sphincter was treated in a like manner (the lateral portions of the sphincter having maintained their relation to the cut edge of the rectum); then the rectum was cut way from its attachment to the upper margin of the vaginal fistula, drawn down, and stitched to the sphincter. In this way the cavity of the rectum was cut off from that of the vagina, the anterior rectal wall filling the opening. As the sequel showed, it would have been better to stitch the wall to the opening, removing the stitches on the third or fourth day.

The next step was the closure of the sphincter. The incision in the post-anal region had closed, so that the superficial extent was an inch and a half, the depth being about three quarters of an inch. The two faces of the cut had now been covered by a thick cicatricial structure; this was pared down, and sutures were introduced as in perineorrhaphy. So much of the cicatricial membrane had been unwisely removed that, when the sutures were tightened, they tore out of the loose ischio-rectal tissue at the bottom of the wound, making it impossible to approximate the surfaces in their entire extent; it became necessary, therefore, to introduce and bring them out full two inches from the incision, well back on the buttock. Quills were then placed at the ends, and upon these the sutures were tightened. In this way the tension upon the tissue at the bottom of the incision was so far diminished, the lines of the sutures being nearly straight, that perfect apposition was obtained. The cut edges of the sphincter were connected by one suture passed close to the edge, as in the repair of this muscle when torn from above. The sphincter being relaxed, no tube was introduced to allow of the escape of flatus, but the bowels were kept constipated for a week, and were then moved without accident.

The result of the operation was not perfect, but enough success was obtained to add greatly to the patient's comfort. The post-anal region was closed to the edge of the sphincter, but the attachment of the rectum to the anterior margin of the sphincter was imperfect, so that the vaginal fistula remained. With the patient standing or sitting, however, the anterior rectal wall prolapsed enough to close the opening by a ball-valve action.

The net result of the first operation was the restoration of the patient to a sufficient degree of health to permit her to work daily as a dressmaker, the entire removal of pain and, with it, of the constipation—the prolongation of a useful life for two and perhaps a greater number of years. The result of the second was freedom from constant involuntary evacuation of feces and gas, for, unless the bowels are loose, a rare event with her, she has sufficient retentive power for self-protection.

The subjoined report and drawing, made by Dr. W. H. Welch, sufficiently explain the nature of the growth:

All of the coats of the rectum are greatly thickened. The situation of the mucous membrane is occupied by a new growth of the following characters: In a stroma of reticulated or adenoid tissue lie imbedded irregular tubular glands lined by cylindrical epithelium. These tubes are much more irregular in shape than the normal glandular tubes of the rectum. They frequently send off prolongations, which anastomose with each

other. The epithelial lining has in places the characters of the so-called goblet-cells. These glands occupy an extent of tissue of about four times the normal thickness of the mucous membrane. Occasionally the gland spaces are filled with epithelial cells. The intertubular tissue is extremely rich in small round cells.

The outer coats of the rectum are thickened by an hypertrophy of the muscular coats and by a new growth of dense fibrous tissue.

The tumor is an adenoma. The new-formed glands are atypical in arrangement, shape, and structure, which gives to the structure a malignancy which simple adenomata do not possess.

Many of these tumors of the rectum have all the clinical characters of carcinoma of the rectum. Secondary growths may form in the liver and other organs, of the same character as the primary growth.

Writers differ as to the classification of these atypical adenomata; thus, Cornil and Ranvier describe and picture them as cylindrical-celled epithelioma; Harrison Cripps, in his elaborate monograph on "Tumors of the Rectum," gives beautiful drawings of this form of tumor, and calls it cancer. While recognizing the malignancy of these growths in many cases, it seems preferable to call them atypical adenomata. The accompanying sketch shows the leading characters of the new growth.

Writing at this date, it may not be out of place to reproduce a summary of the reported cases that appeared in the "Medical News" of October 13, 1883. Under the heading "Is Extirpation of the Cancerous Rectum a Justifiable Operation?" we find the following:

Lest this number may be deemed too limited to represent the actual state of facts, we have to add to the cases of Czerny 198 additional ones of which we have a record. Of the entire number, or 223, 180 recovered, and 43, or 19·3 per cent., died. Of 142 in which the final result is known, 64 remained well for periods varying from two months to ten years, and 78, or 54·9 per cent., recovered. Omitting the cases in which the recovery at the date of the last report had lasted from two to sixteen months, we have 35 cases in which there was no reproduction of the disease for two years and upward, 13, indeed, having remained well for between five and ten years, so that 15 per cent. of the entire 223 were in all probability permanent cures. If three years and upward be regarded as still better representing a probable immunity from recurrence, the 28 cases which come under this category show 12·5 per cent. of cures, while the 21 cases which represent four years and upward make the number of cures 9·4 per cent. With these results before us, and they are far better than have as yet been secured for carci-

noma of other organs, we have no hesitation in answering our self-imposed question in the affirmative.

NOTE, April 1, 1884.—The patient has just come back to the hospital. An examination shows that the disease has returned, having now invaded the tissues in the ischio-rectal fossa, and the rectum being filled with a diseased mass. The vaginal fistula is no larger than a buckshot. Her general health is very good, and she has been able to work for the last ten months. The returning disease has pushed in between the cut end of the rectum and the sphincter, nearly closing the anus. The latter can easily be dilated, but the infiltration into the buttock is too extensive to justify more than this.

A CASE OF MALIGNANT PUSTULE CAUSED BY THE BITE OF A FLY.

BY A. C. GRIFFIN, M. D.

THE following case, which occurred in my practice, I deem worthy of notice on account of its comparative infrequency:

The patient, a male, aged thirty-five, of fair physique, and a moderate drinker, came into my office to be treated for a very painful swelling of the left cheek, for which he could assign no cause. It had grown very rapidly since the preceding day, when he had first noticed it as a small pimple.

On examination, the swelling was found to be of a somewhat circular form, about 25 mm. in diameter, and extending through the whole thickness of the cheek, implicating the skin and mucous membrane, to which it was firmly adherent. The swelling was indurated to such an extent as to greatly resemble the ivory hardness of carcinoma. It was extremely sensitive to pressure, and the patient complained of very severe lancinating pains radiating through it. In the center of this swelling, 15 mm. above and 20 mm. external to the ala of the nose, was situated a small ulcer, which was covered by a closely adherent layer of pus of a grayish, unhealthy appearance. Surrounding the ulcer was a wide areola of an angry red, erysipelatous hue. The cervical and submaxillary lymphatics were enlarged and tender to pressure. Pulse 120, temperature 103.2° F., tongue slightly coated, violent headache, and complete anorexia. The patient complained of great prostration, excessive nervousness, and an extreme fear of impending death. On questioning him in regard to this severe and sudden prostration, the patient remembered that, while eating dinner the previous day at a restaurant, he was bitten on the cheek by a large fly at the exact seat of the ulcer, but he had not suspected that as a cause.

I made a diagnosis of septic infection, or what I believe to be malignant pustule. I at once thoroughly cauterized the ulcer with pure carbolic acid, applied cooling and sedative lotions to the swelling, and placed the patient on full doses of quinine and alcohol. Sufficient morphine was given to relieve pain and quiet nervousness. On the following day the condition of the patient was much worse, the induration had greatly enlarged in size, extending from the upper lip to the orbital cavity, also implicating the nose, being fully 60 mm. in diameter. The ulcer had also increased by a process of sloughing to a diameter of 20 mm.; the destruction of tissue was quite extensive, as the ulcer extended nearly through the thickness of the cheek. The edges of the ulcer were composed of exuberant granulations, quite protuberant, and bled quite freely from the slightest contact, and from the cavity thus formed there was a profuse discharge of a thin, ichorous fluid of a peculiarly offensive odor. Delirium now supervened. Pulse 140, temperature 104.8° F., tongue heavily coated with a brownish-yellow fur, the bowels

were constipated, the cervical lymphatics were very much enlarged, quite tender to pressure, and threatening suppuration; the patient meanwhile complained constantly of severe pain. Pure carbolic acid was again applied to the ulcer, to destroy the exuberant granulations, and to prevent, if possible, further septic absorption. Poultices were applied over the swelling, morphine, quinine, and alcohol were given in increased doses; a mild cathartic was also administered. The patient grew progressively worse until the sixth day from the receipt of the bite, when his condition was one of extreme prostration, with very little hopes of recovery. The treatment had consisted of thorough cauterization of the ulcer each day, poultices to the swelling, and the free use of alcohol and quinine, with sufficient morphine to allay the pain. By the aid of this free stimulation the patient was enabled to overcome the virulence of the septic inoculation, and on the seventh day his condition had slightly improved. The induration became somewhat softer and slightly diminished in size, the ulcer began to assume a healthy appearance, normal granulations sprang up covered with laudable pus, and the areola had become less vivid in color. From this time on the case progressed favorably, the induration of the cheek and the swelling of the glands subsided, the cavity left by the ulcer filled up and healed, leaving a moderate-sized cicatrix, and the patient's general condition advanced steadily toward its normal standard.

On making inquiries about the restaurant, it was found that the employés had been in the habit of throwing waste scraps of meat and other refuse into a back yard. This practice having been complained of, it was stopped by an order from the Board of Health, and for several days afterward the flies swarmed about the restaurant, annoying all by their savageness. So far as could be learned, this was the only person of those exposed whose physical state was in a condition susceptible to the inoculation of septic material, which was undoubtedly conveyed to the blood of this patient by the bite. The fly, which was a common green-bottle or carrion fly, was killed on his cheek by a friend who was dining with him. The fly had bitten sufficiently to draw blood, and it was from this point as a focus that the malignant pustule began its career. That it was a malignant pustule, I think the clinical evidence fully bears out. Had material been convenient, I should have availed myself of the opportunity of submitting it to the crucial test, which is by inoculation. Pollender professes to have detected the presence of the *Bacillus anthracis* in the discharges from malignant pustule, but other observers have failed to verify this.

Although malignant pustule is not so very uncommon in France, Germany, and Switzerland, yet I believe that it is rarely met with in the eastern part of the United States, its occurrence being more frequent in the cattle-growing States of the South and West, where it is contracted from cattle suffering from murrain. It is also occasionally contracted by those who work in curled hair, wool, or rags, or handle hides or dead animals. Veterinary surgeons are occasionally infected with it. Several cases are related by Gross, in which the contagion was conveyed by the proboscis of the green carrion fly.

Of the nature of the disease but very little indeed is known. Heusinger believes it to be malarial in origin, operating through certain nervous ganglia of the blood-ves-

sel system, producing stasis, transudation, and extravasation, and forming in the foci of local disturbance some peculiar septic material, which, taken up by the lymph or blood, and acting as a ferment, is thus disseminated throughout the body. Brauell and Sanson believe that the disease is influenced by a geographical distribution, being limited to certain soils. That at any one time sufficient septic material is introduced into the blood to cause death, I do not believe. Primarily I consider it a purely local lesion, but, once introduced into the system, from whatever nidus it may select as favorable to its growth, rapid proliferation of the septic elements goes on, and it is the continued absorption of these that finally overwhelms the patient.

I believe that the proper treatment in cases of septic inoculation or malignant pustule lies in the prompt and thorough excision or cauterization of the point of inoculation, endeavoring by these means to prevent the growth and proliferation of the morbid elements, and thus check the absorption of those materials which would contaminate the whole system.

As for general treatment, stimulation should be carried to its fullest extent, and the best of the stimulants will be found to be alcohol. Quinine should be given in large doses to obtain its antipyretic, as well as its antiseptic, effects. Opium should be administered in quantities sufficient to quiet pain and allay nervousness. The bowels should be kept open by laxatives or mild cathartics. Poulices also seem to give some relief, especially when to them is added some sedative, as tincture of opium.

Book Notices.

Practical Pathology. A Manual for Students and Practitioners.

By G. SIMS WOODHEAD, M. D., F. R. C. P. E., Demonstrator of Pathology in the University of Edinburgh, etc. With one hundred and thirty-six Colored Plates. Philadelphia: Henry C. Lea's Son & Co., 1884. Pp. xv+484.

This book presents a very attractive appearance. The paper is good, the printing is excellent, and the colored plates are alluring. But in reality these are non-essentials. The questions which most interest the student, whether advanced or a beginner, are: Does the text give the accepted views in pathology? and Do the plates adequately and correctly illustrate the text? Answered affirmatively, the book at once has special merit; answered negatively, it goes immediately with the horde of honest efforts, but lamentable failures, by which it has been preceded. Probably "alf and 'alf," as the near neighbors of the author would say, will better describe the true status of the work than either an unqualified assent or dissent.

In the first place, as to the text. The general scope of the book is elementary. The matter is presented in a fairly systematic manner, and the text is sufficiently well written, although the views given do not indicate special erudition or research, and in many places fall unnecessarily short of what the modern student in pathology has a right to expect from such a volume.

To illustrate, the author's text leads the reader to the conclusion that locomotor ataxia is primarily a disease of the con-

nective tissue, whereas excellent, if not the best, and probably the majority of authorities maintain that the primary lesion pertains to changes affecting the nerve tubes, which are not mentioned at all, except in connection with secondary changes. The addition of two or three lines would have given the student a much broader view of the subject than has been presented.

The first chapter is devoted to post-mortem examinations, and the writer has evidently followed Virchow closely—none too closely, however, for the text might have been improved by making complete rather than partial quotations. To simply "remove the contents of the pelvis," "cut out the rectum," "remove and note the condition of the vagina," "take out the semilunar ganglia," "remove the liver," etc., will prove to be very meager instruction for the man who undertakes his first autopsy.

Chapter II is entitled "Pathological Histology," but its contents refer merely to the steps necessary to be taken before the student can begin the study of the structure of morbid products.

Instruments, reagents, mounting sections, hardening tissues, section-cutting, section-staining, etc., receive the usual amount of attention, and, for the most part, the directions and descriptions given are plain and practical. Methylated spirit, however, should be banished from the pathological laboratory. Surely such a chapter would be incomplete without reference to Valentin's knife, although there is nothing in the entire armamentarium of the modern histologist or pathologist with which it can be appropriately compared except a dirty stylographic pen, with the chances vastly in favor of the pen.

If to this the manipulation for preparing Farrant's mounting fluid be added, recommended by the author, a combination will be effected which will surpass any exciting cause of profanity ever made known. We believe, also, that the student will be disappointed if he places implicit confidence in all the author says concerning the use of methylaniline, and will find that it is not so easily handled, if good results are obtained, as he would be led to infer from the text.

In Chapter III the author begins the study of the morbid anatomy of the different organs of the body, directing attention first to the liver. The general plan adopted in this chapter extends throughout the book—that is, the histology of the organ is given first, and this is followed by the pathological anatomy.

It is worthy of notice that the author regards cloudy swelling, fatty degeneration, and fatty infiltration as identical in nature, varying only in degree, and yet he describes a degeneration of the nucleus as well as the protoplasm of the cell, which manifests itself microscopically in a mass of granules without any fat droplets.

The author also prefers the name "biliary" cirrhosis to "hypertrophic" cirrhosis, the term in general use.

In the section on acute yellow atrophy of the liver the author speaks of an interstitial inflammation and of the existence of a number of small bile-ducts in the newly formed tissue. This is by no means beyond dispute, and the text would have been less likely to mislead had it been less dogmatic.

Chapter IV contains the histology and the morbid anatomy of the various diseases of the heart. Here it is stated distinctly that cloudy swelling is *not* the earliest stage of fatty degeneration, and the statement is based upon the effect produced by such reagents as ether, chloroform, and osmic acid, which leave the cloudiness unaffected.

The ten succeeding chapters are devoted to the blood-vessels, the kidney, the lung, the spleen, the alimentary canal, bone and joints, the nervous system, tumors, parasites, and vegetable parasites.

Scattered here and there throughout are statements which fall under the general criticism already given. Just here we see

one with reference to Weigert's staining for the central nervous system. It is that the method is of no use, according to Weigert, for peripheral nerves. We have no doubt that Weigert does not entertain this opinion, for one of the most satisfactory differentiations in nerve tissue we have ever seen was a section of the sciatic nerve stained according to the acid-fuchsin method, and we believe that it is recognized as one of the most admirable means of demonstrating the axis-cylinder which have ever been offered.

With regard to the illustrations: Beautiful colors are attractive, but it has always been a question whether or not they add to the intrinsic value of the plate. If such plates are colored just enough, and no more, their value may be increased as illustrations, provided the original drawing has been correctly sketched and the transfer made artistically. To take these steps successfully is a work of art of high order, and, unfortunately, in a large proportion of instances is so poorly done that the practical worker with the microscope is greatly disappointed when he finds himself, after careful manipulation, unable to reproduce the picture given in the book.

In the present instance the work has not reached the degree of excellence which has been exhibited in publications that have from time to time been presented to the profession. There is such a marked difference between the illustrations from Klein and Noble Smith, Thierfelder, Kyber, and others, and those prepared by the author, that it is at once apparent, even on the most superficial examination. Some of the original illustrations are fairly creditable as pictures, although failures as illustrations of morbid anatomy; others are unsatisfactory, both as colored plates and as pathological sketches, while still others are mere daubs.

The general criticism is that the author's illustrations of low magnifying power fail to show what they should, and those of high magnifying power give exaggerated and, not infrequently, incorrect notions. For example, the illustrations of common cirrhosis of the liver are failures; a certain number of red lines and dots are not sufficient, while the student will work for a long time before he will encounter such a beautifully penciled specimen as is illustrated by Fig. 23. The illustrations of cloudy swelling of the liver show nothing of the lesion; all that can be seen is a series of lines and dots. The plate showing the cortex of the kidney in a state of chronic venous congestion is faulty, for the reason that the epithelia of the tubules do not present themselves with such clean-cut dividing lines. If so distinct in the tubules, why should not the bodies of the epithelial cells covering the capillary tuft of the Malpighian body and lining Bowman's capsule have been mapped out quite as distinctly, instead of being given as a few purple dots representing the nuclei?

It is very doubtful if any one can recognize the intention of the author in Fig. 61 without consulting the text. It is a failure as a staining with picro-carmin, and an abortion as an illustration of the second stage of lobar pneumonia. Fig. 60 ($\times 50$) does not show what it should, even with this magnifying power. Fig. 54 is an illustration of staining with picro-carmin, but it has not until now been our privilege to see the red-blood corpuscles colored distinctly green. The only near approach which the author's illustrations have to those by Kyber, Thierfelder, and others, is in Fig. 79; but this is none other than a failure as an illustration of the morbid anatomy of the spleen in leucocythemia. Fig. 123 (scirrhus cancer of the breast) is unworthy of a student who has worked industriously for six months in a pathological laboratory. Fig. 119 (adenoid cancer) is exceedingly coarse as a work of art, and as an illustration of disease it is nearly worthless.

The reviewer is aware that these are unpleasant criticisms, but he believes they are fully justified on close inspection from

a scientific standpoint. The author has evidently failed to grasp the details essential to the making of good colored plates.

While there is a good deal in this book that will prove acceptable to students, there is very much that will prove unsatisfactory to the practical worker with the microscope and the advanced student in pathology.

Correspondence.

LETTER FROM PHILADELPHIA.

The Medical Colleges.—The County Society and the Question of the Admission of Women.—The Medical Jurisprudence Society.—The Hospitals.

PHILADELPHIA, April 7, 1884.

On the first of May the medical department of the University of Pennsylvania will graduate a class of about a hundred, four of whom have taken the four years' course. The freshman class numbered one hundred and forty, which is the largest class since the school was reorganized. Professor Alfred Stillé has resigned the chair of the practice of medicine, and it is thought that in all probability his successor will be Dr. William Pepper, the present professor of clinical medicine and Provost of the university. At the recent commencement of the Jefferson Medical College the degree of doctor of laws was conferred on Professor J. M. DaCosta, of Philadelphia, and Professor Benjamin Silliman, of New Haven, and the degree of doctor of divinity on the Rev. J. F. Dripps. I understand that the Medico-Chirurgical College, which has lost several members of its faculty by death, is about to come under different management, and that it will be made in every respect a superior institution. It is believed that there is room for a third medical school in this city, and the professional standing and character of the men who are understood to be concerned in the reorganization of the Medico-Chirurgical may be inferred from the fact that nearly all of them are connected with the Polyclinic. Whether the two institutions will be merged into one, or not, is a question which can not now be answered. At the Woman's Medical College Dr. William W. Keen has recently been elected professor of surgery.

The Philadelphia County Medical Society has again rejected a woman candidate for membership, but at the same meeting, that of April 2d, an amendment intended to settle the question by making women ineligible for membership failed to get the requisite two-thirds vote for adoption.

The Medical Jurisprudence Society promises to be popular with both the professions concerned, each of which is represented by able and prominent men. At this week's meeting, with Professor Gross in the chair, a paper will be read on "Trial by Jury," and Professor J. Reese will read a paper on "Medical Experts." This will be the second monthly meeting of the society.

Dr. D. Hayes Agnew has resigned from the medical staff of the Pennsylvania Hospital, on account of the growth of his other engagements. The old lying-in wards of the Philadelphia Hospital having become so pestiferous as to forbid their further use, an appropriation of \$8,000 has just been made by the City Council, to build two new maternity wards.

THE GARFIELD MEMORIAL HOSPITAL.—It is reported by the Washington correspondent of one of the Boston newspapers that a struggle has arisen between two sections of the board of lady managers, one section being clamorous in favor of allowing the practice of homoeopathy in at least one wing of the hospital.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, APRIL 12, 1884.

THE ADJOURNED MEETING OF THE COUNTY SOCIETY.

THE meeting held last Monday evening, for the specified purpose of listening to the report of the Committee on the "Collective Investigation of Disease," seems to have devoted its chief attention to a matter altogether foreign to the special order for the evening, namely, the consideration of the attitude which the society ought to take on the measure of legislation looking to the regulation of practice by midwives. The reading of the committee's report was even cut short—its conclusion and the discussion thereon being postponed—in order that the meeting might proceed to the consideration of the matter of midwifery practice. We can only infer, either that but a lukewarm interest was felt in the committee's report, or that the midwifery bill was looked upon as claiming the society's immediate attention. Of these two inferences, we prefer to think that the latter is the correct one.

As the matter stands now, we can not allow that the society's "collective investigation" of the subject of intestinal obstruction has been so conducted as to heighten the value that should be attached to inquiries of the sort. As we feared would be the case, the report was chiefly a recital of clinical histories, preceded by a meager statistical summary, the great therapeutic questions involved being scarcely touched upon except by the individual contributors. On account of the reading of the report not having been finished, it is impossible to say how many of the latter there were whose work was lost to the meeting, or to judge of the character of the contributions thus buried. This we may say, however—and it is pleasant to be able to point to a redeeming feature—that the cases contributed by Dr. Burchard and Dr. Atherton are interesting and instructive, and that the remarks added by those gentlemen to their reports were of a nature to shed considerable light on the subject under investigation. If the society is to make any further efforts in the way of "collective investigation," we trust that the committee will lay aside its modesty, and really give shape to the material it may have to work with. We can not suppose that in this instance no effort was made to secure the co-operation of the two or three surgeons in the city who would have been able to bring a well-digested personal experience to bear, but we would suggest that in the future, in case those most qualified to take part can not be induced to do so, the proposed investigation be dropped.

Turning our attention now to the threatened incorporation of a college of midwifery, with the attendant legal recognition of midwives as practitioners, it is to be hoped that the committee appointed to proceed to Albany will succeed in strangling the bill now pending. In the light of Dr. Piffard's statement

at the meeting, the Committee on Legislation of the Medical Society of the State of New York must be absolved from the suspicion of negligence that was suggested in our last issue. An extension of that committee's field of action and an increase of the funds at its disposal may commend themselves to the next meeting of the State society, in view of the strait to which the profession has been brought in this matter by the lack, apparently, of any adequate provision for meeting such schemes of legislation promptly. Whatever may be the fate of the particular bill with which the deputation to Albany has to deal, the broad question is likely to remain, as to what legislation, if any, is advisable in the matter of recognizing and regulating the practice of midwives. Cogent as Dr. Garrigue's argument was against tolerating those functionaries under any circumstances, the midwives are with us, and how they should be dealt with will yet have to be decided.

THE NIAGARA UNIVERSITY AND ITS MEDICAL DEGREE.

THE medical department of Niagara University, of Buffalo, is meeting with trouble very early in its existence. Before it has completed the first year of its work, the legality of its degree is questioned by the board of censors of the Medical Society of the County of Erie. This in itself would amount to at least a temporary misfortune for the school, but, when it is added that an elaborate opinion has been published in the newspapers, setting forth the reasons which have led the attorneys of the society to the conclusion that the university can not legally grant the degree of doctor in medicine, it will be seen that additional embarrassment is thrown upon the institution for the time being, for the public is apt to be prejudiced at the outset in favor of the opinion first in the field. In the interest of justice, therefore, we think it is to be regretted that the legal opinion in question has been laid before the community while yet, so far as we are aware, the matter has not come before the courts. Especially is this fact to be regretted when the publication is made under such head-lines as we find in one of the Buffalo papers: "Niagara University. The Erie County Medical Society gets after an Institution which Professes to Make Doctors—A Legal Opinion. Illegal Medical Degrees."

It is unquestionably proper for the society to interest itself in regard to the legality of the degrees granted by any institution within the county, and, in case of doubt, to test the matter in any legitimate way, but we can not suppose that the society has been the mover in the publicity given to the inquiry, especially as the opinion given by its attorneys is qualified by a doubt as to the construction that should be put upon an act of the Legislature that has a material bearing on the question. It seems that it has been the custom of the Legislature, when chartering colleges, to invest them with the same privileges and powers in regard to degrees as those enjoyed by Columbia College, instead of defining those privileges and powers specifically in the individual cases. In the case of the Niagara University, according to the attorneys, the question turns upon whether its charter, as recently amended, invests it with the same degree-granting powers as those now held by Columbia College, or

only with those that Columbia enjoyed under its original charter, before the supplementary act of 1810 was passed, defining the powers of the college more specifically. Besides, it does not appear certain that the original charter of Columbia College did not carry with it the right to confer the degree of doctor in medicine, although the attorneys think it did not.

Pending a judicial exposition of the powers of the colleges in the State, and of the bearing of the various acts of the Legislature on the status of Niagara University, it can scarcely be said to have been shown logically that the university has exceeded its prerogative in conferring the degree in medicine. It is doubtful, we think, if this particular case ever comes before the courts, for a readier way of settling the point at issue, and one that will in all probability be resorted to by the university, is to ask the Legislature now in session to pass a supplementary act defining its powers.

ELOCUTION IN MEDICAL LECTURES.

COMMENTING ON M. Remy's first lecture in the course in physiology given by him as M. Bédard's substitute, the "*Progress médical*" takes occasion to make some particularly wholesome reflections on the methods of scientific teaching in vogue in Paris, especially in the demonstrative courses. We are surprised to learn from our contemporary's article that M. Remy's lecture-room is defective in some of the appliances needed for efficient demonstration, including even such commonplace matters as facilities for illustration. But it seems that it is not alone in respect to these material features that the French scientific courses are in need of improvement, for the journal in question takes pleasure in contrasting M. Remy's clear and precise statements with what it terms the turgid periods void of sense still so frequently brought into play by the lecturers of Paris, adding that the students of the present day are not much taken with rhetoricians, but, without being wholly indifferent to the form in which instruction is given them, prefer to have the greatest number of facts stated in as few words as possible.

It seems to us that the Paris journal's criticism strikes to the kernel of one thing that lies at the door of scientific teaching, not only in France, but elsewhere, as a prime obstructive. Not that eloquence is always and necessarily out of place in scientific courses, for in some of its phases the study of natural phenomena leads the mind to a state in which the words that clothe an idea, or even a statement of fact, together with the glance, the mien, the gesture with which it is emphasized, play a leading part. Moreover, what is termed the personal magnetism of a lecturer is not to be set down as merely meretricious; it enters into and vivifies the impression made, as the "atmosphere" of a painting lifts it above the level of a photograph. But eloquence is only in place, and therefore only effective, when it flows in obedience to the natural demands of the theme, and such demands are not common in scientific expositions. Clearness is the one element that, above all else, should characterize a lecturer's talk when he has to deal with technical matters, and the main features of clearness are simplicity and precision.

MINOR PARAGRAPHS.

THE "ASCLEPIAD."

This is the title of a new serial publication, termed "A Book of Original Research and Observation in the Science, Art, and Literature of Medicine, Preventive and Curative." It is to be issued quarterly, and, judging from the first number, each part is to contain ninety-six pages. Dr. Benjamin Ward Richardson, of London, is the author—not the editor, for the entire contents are of his own writing. The first number shows a variety of contents such as was to be expected from an author of Dr. Richardson's versatility, and all the articles, eight in number, are very readable. The matter of an author's issuing a serial made up wholly of his own articles is not altogether new, and such a venture is quite likely to prove welcome, especially when the writing comes from a man so well known and so highly thought of as Dr. Richardson. We look forward with pleasure to subsequent issues of the "Asclepiad."

THE "QUARTERLY EPITOME OF AMERICAN PRACTICAL MEDICINE AND SURGERY."

This well-known periodical, "collateral to 'Braithwaite's Retrospect,'" enters with its March number upon its fifth volume under the guidance of a new editor—new to the journal in question, but a veteran in the work of medical editing—Dr. Wesley M. Carpenter. To those who know Dr. Carpenter, and he reckons among his acquaintances and, we may truly add, his friends nearly all those members of the profession who during the past ten or fifteen years have attended the meetings of our local societies or those of the national societies—to all these we need not say that he possesses to a rare degree the faculty of conducting a journal of this character in such a manner as to give his readers (what the "Epitome" has always aimed to give) "the cream of medical literature." To the few who do not know Dr. Carpenter we have only to say that, if they will read the "Epitome," they will not be slow to discover that he knows the difference between an abstract and a clipping, and, furthermore, that he has the art of making unusually satisfactory abstracts. Add to this a wide knowledge of medicine and an exceptional conscientiousness, and we have the picture, both of Dr. Carpenter and of what the editor of such a journal should be.

THE PHILADELPHIA MEDICAL DIRECTORY.

We have received a copy of the "Medical Directory of Philadelphia," for 1884, and we find it a distinct improvement on the issues for previous years. The lists of names include those of homeopathic physicians, registered practitioners without a diploma, veterinarians, dentists, and apothecaries. The usual information is given in regard to the charitable institutions, but the data concerning the medical societies are exceedingly meager. The arrangement of the matter is such as to facilitate hasty reference. The volume is edited by Dr. Samuel B. Hoppin, and published by the Messrs. Blakiston.

THE NEW YORK DISPENSARY.

It is evident from the ninety-fourth annual report of the board of trustees of this institution, for the year 1884, that the good work which it has done for a long term of years is not declining. Indeed, certain indications are to be noted that it is more alive than ever to the advance of the work of charity. Among these, we may mention the comparatively new feature of the providing of trained nurses to accompany the district

physicians in their rounds, a plan which, we understand, has been adopted by one of the other dispensaries also, the Demilt.

NEWS ITEMS, ETC.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 8, 1884:

DISEASES.	Week ending April 1.		Week ending April 8.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	8	5	4	1
Typhoid Fever	5	3	6	0
Scarlet Fever	96	12	89	13
Cerebro-spinal meningitis	6	5	6	6
Measles	68	9	63	13
Diphtheria	42	16	47	18
Small-pox	0	0	1	0

THE PROPOSED MARINE HOSPITAL FOR NEW YORK.—The purchase of the Seaman's Retreat property, on Staten Island, has been reported upon favorably in the House of Representatives.

THE NEW YORK STATE BOARD OF HEALTH.—Mr. Erastus Brooks, of Richmond County, Dr. J. E. Delavan, of Albany County, and Mr. George W. Cooke, of Ulster County, have been appointed members of the board.

"RYE AND ROCK" CONFECTIONERY, as was confessed by the makers on the occasion of a hearing before Health Commissioner Raymond, of Brooklyn, recently, is flavored with an extract, and mention was made of fusel oil being used in the manufacture. A more gratifying admission was to the effect that the recent talk about the unwholesomeness of the product had led to a falling off in its sale.

THE LAY NURSES OF THE PARIS HOSPITALS do not seem to have given the satisfaction that was expected of them at the time they were substituted for the Sisters of Charity, judging from a report to the effect that a well-known surgeon of *la Charité* has written a letter denouncing the exclusion of the latter.

OLEOMARGARINE.—The bill prohibiting the manufacture and sale of this factitious butter within the limits of the State of New York has passed the Senate, with an amendment reducing the penalty to between \$100 and \$500.

CHARITABLE BEQUESTS.—By the will of the late Mrs. Oswald Ottendorfer, the German Hospital and the German Dispensary are each to receive \$10,000, and the German Hospital of Newark, N. J., \$5,000.

SANITARY APPOINTMENTS IN BOSTON.—The Boston board of health has appointed Mr. George W. Forrestall superintendent of health, Dr. John H. McCullum city physician, and Dr. Arthur C. Griffin port physician.

THE ADULTERATION OF DRUGS IN MASSACHUSETTS.—A remonstrance has been laid before the Massachusetts Legislature against any change in the present law relating to the adulteration of drugs. It is signed by Dr. Alfred Hosmer, the president of the Massachusetts Medical Society, Dr. George C. Shattuck, Dr. George H. Lyman, Dr. Benjamin E. Coting, and Dr. Henry W. Williams. The document urges that the United States Pharmacopœia should be the only standard of the strength and purity of drugs.

SMALL-POX IN PENNSYLVANIA.—A report from Easton last week represented that a number of immigrants from Hungary, by way of New York, had been taken from a railway train and

placed in the Lehigh County Almshouse, having been found to be suffering with small-pox.

THE NEW YORK ACADEMY OF MEDICINE.—At the next meeting of the Academy, Thursday evening, April 17th, Dr. Robert Abbe will read a paper entitled *A Study of "Dupuytren's Contraction of the Hand."*

THE INSPECTION OF MEAT IN NEW YORK is in a fair way to be made much more thorough than it has been heretofore, bills having been introduced into both houses of the Legislature providing for the appointment of five inspectors of meat by the board of health, and making it a punishable offense to offer for sale any meat that has not been inspected by them, the inspection to be repeated every second day until the meat is sold.

THE ISOLATION OF CONSUMPTIVE SOLDIERS, according to the "Progrès médical," has been decreed in the military department of Prussia.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from March 30, 1884, to April 5, 1884:*

WOODHULL, ALFRED A., Major and Surgeon. Granted leave of absence for twenty-two days, to take effect about April 6, 1884. Par. 13, S. O. 72, A. G. O., March 28, 1884.

WHITE, ROBERT H., Captain and Assistant Surgeon. To be relieved from duty at U. S. Military Academy, West Point, N. Y., August 28, 1884. Par. 7, S. O. 74, A. G. O., March 31, 1884.

MEARNS, EDGAR A., First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Verde, A. T. Par. 1, S. O. 22, Headquarters Department of Arizona, March 19, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending April 5, 1884:*

WALES, P. S., Medical Director. Granted one year's leave of absence from March 28th, with permission to leave the United States.

BATES, N. L., Medical Inspector. Ordered to Washington to attend sick officers.

BRADLEY, M., Medical Inspector. Ordered to continue duty at League Island Navy Yard.

WHITAKER, H. W., Assistant Surgeon. Ordered to Naval Rendezvous at Philadelphia, Pa.

GUNNELL, F. M., Surgeon-General. Appointed Chief of Bureau of Medicine and Surgery, and Surgeon-General of the Navy, with the relative rank of Commodore, from March 27, 1884.

RUSH, C. W., Passed Assistant Surgeon. Ordered to Naval Academy.

MCMURTRIE, D., Surgeon. Detached from Naval Rendezvous, Philadelphia, and to await orders for duty at Navy Yard, Washington, D. C.

NELSON, H. C., Medical Inspector. Ordered before Retiring Board.

GORGAS, A. C., Medical Inspector. To be Medical Director from the 4th of March on the Active List.

MARINE-HOSPITAL SERVICE.—*Official List of Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service—January 1, 1884, to March 31, 1884:*

ESSENDEN, C. S. D., Surgeon. To proceed to Cairo, Ill., and Memphis, Tenn., as Inspector, March 5, 1884.

PURVIANCE, GEORGE, Surgeon. Granted leave of absence for thirty days, February 16, 1884.

SMITH, HENRY, Surgeon. To rejoin his station at Norfolk, Va., March 7, 1884.

IRWIN, FAIRFAX, Passed Assistant Surgeon. Relieved from

duty at Norfolk, Va.; to assume charge of Cape Charles Quarantine Station, March 7, 1884.

CARMICHAEL, D. A., Assistant Surgeon. To report to Surgeon Purviance for examination for promotion, March 5, 1884.

ARMSTRONG, S. T., Assistant Surgeon. To report to Surgeon Fessenden for examination for promotion, March 5, 1884.

BENNETT, P. H., Assistant Surgeon. Leave of absence extended ten days, January 18, 1884.

AMES, R. P. M., Assistant Surgeon. Detailed for temporary duty on relief-boat, Ohio River Flood Sufferers, February 16th, and March 1, 1884.

DEVAN, S. C., Assistant Surgeon. Upon expiration of leave of absence, to proceed to St. Louis, Mo., for temporary duty, February 6, 1884.

KALLOCH, P. C., Assistant Surgeon. To proceed to Charleston, S. C., for temporary duty, February 1, 1884.

BEVAN, A. D., Assistant Surgeon. Granted leave of absence for seven days, March 13, 1884.

WASDIN, EUGENE, Assistant Surgeon. Granted leave of absence for fifteen days, March 4, 1884.

BATTLE, K. P., Assistant Surgeon. To proceed to New York, N. Y., for temporary duty, February 4, 1884.

Resignation.

COOKE, H. B., Passed Assistant Surgeon. Resignation accepted by the Secretary of the Treasury, to take effect February 5, 1884. January 31, 1884.

Appointment.

BATTLE, KEMP P., M.D., of North Carolina, having passed the examination required by the Regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, February 2, 1884.

Promotions.

CARMICHAEL, D. A., Passed Assistant Surgeon. Promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from March 1, 1884. March 18, 1884.

ARMSTRONG, S. T., Passed Assistant Surgeon. Promoted and appointed Passed Assistant Surgeon, by the Secretary of the Treasury, from April 1, 1884. March 28, 1884.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, April 14th:* New York Academy of Sciences (Section in Chemistry and Technology); New York Ophthalmological Society (private); New York Medico-Historical Society (private).

Tuesday, April 15th: New York Academy of Medicine (Section in Theory and Practice of Medicine); New York Obstetrical Society (private); Medical Society of the County of Kings; Ogdensburgh, N. Y., Medical Association; Medical Society of the County of Passaic, N. J.

Wednesday, April 16th: New Jersey Academy of Medicine (Newark); Medical Society of the County of Windham, Conn.

Thursday, April 17th: New York Academy of Medicine; Medical Societies of the Counties of Hartford and Tolland, Conn.

Saturday, April 19th: Roman Medical Society (private).

OBITUARY NOTES.

PROFESSOR ALLEN THOMSON, OF EDINBURGH.—We regret to learn, from the "Medical Times," of London, that Allen Thomson, M.D., LL.D., F.R.S. Lond. and Edin., died recently, in the seventy-fifth year of his age. Professor Thomson was a most successful teacher of anatomy and the author of several exceedingly important papers on embryological subjects, being perhaps best known in this country by his chapter on Embryology in Quain's "Anatomy."

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE.

Meeting of April 3, 1884.

H. T. HANKS, M. D., Vice-President, in the chair.

THE REMOVAL OF THE PLACENTA.—Dr. H. J. GARRIGUES read a paper on this subject. He did not propose to consider abortion cases. The method which he practiced was that of Credé, described as long ago as thirty years. It was eight years since he had adopted it; when he became connected with the Maternity Hospital it was introduced into his service there, and had given entire satisfaction. In one year four hundred and eight women were delivered; two of them aborted in the fifth and sixth months, respectively, and the placenta was removed piecemeal by means of the dull wire curette and the forceps. Among the remaining four hundred and six there were six cases of retained placenta, and in six the membranes had to be removed after separation of the placenta. Therefore, out of over four hundred cases in which Credé's method had been practiced, in only six had it failed. In four there existed abnormally intimate connections between the placenta and the uterus, and it might be taken for granted that in those cases any amount of pulling on the cord would not have brought the afterbirth away. In six cases, or one and one half per cent., more or less of the membranes were retained; in one of these the whole hand was introduced into the uterus in order to remove them; in the five others the index and middle fingers were employed for this purpose, and no trouble was observed in consequence. Credé had not observed any bad result arise from leaving the membranes in the uterus, and would not advise their removal, as the introduction of the hand might cause infection. Dr. Garrigues had seen very serious post-partum hæmorrhage occur in such cases, and instructed his assistants to remove any part of the afterbirth, whether placental or membranous, which was left in the uterus. Antiseptic precautions being used, the danger from removal of such parts was comparatively small. He formerly used solutions of carbolic acid, a five-per-cent. solution for the hands and a two-per-cent. solution to be thrown into the uterus. Since October, 1883, he had employed a solution of bichloride of mercury, 1 to 2,000.

Credé's method helped nature by her own means; it only increased the strength of the normal contraction of the uterus by which the placenta was expelled. When the third stage of labor was left to nature's own efforts, in some cases expulsion followed immediately upon the birth of the child; in the majority more or less time intervened after the birth of the child before the placenta was thrown off; more or less blood collected in the membranes, and was afterward pushed out in the form of a clot and fluid blood, and in some the placenta did not come off at all. Help was therefore called for. Dr. Garrigues divided the muscles of the uterus into two groups, the proper and the common. The first approximated the walls of the organ; by the second it was drawn backward into the pelvic cavity, and at the same time it was tilted in such a manner by the co-operation of the round and utero-sacral ligaments that the fundus moved forward and the cervix backward, while all the lower bundles probably contributed to the expansion of the os. All these movements were closely imitated by Credé's method. By shortening the third stage of labor, and by increasing the muscular contraction, Credé's method counteracted the tendency to hæmorrhage both immediately, during the third stage, and after labor. During the period at the Maternity Hospital mentioned they had only had two cases of post-partum hæmorrhage, besides

two in which there was a moderate amount of blood lost. In both the cases of post-partum hæmorrhage the bleeding began immediately after the birth of the child, before Credé's method could be practiced. Both patients were exhausted and the latter had blood extravasation all over the body, the case being one of purpura hæmorrhagica. In no case had post-partum hæmorrhage occurred after the expression of the placenta. When properly executed, Credé's method for the expulsion of the placenta was the best for the prevention of post-partum hæmorrhage. Inversion of the womb was prevented, but it could not be too often repeated that the uterus was seized from all sides over the largest possible space, and downward pressure on the fundus should never be practiced except when the womb was contracted. In some cases the whole afterbirth was expelled by this method outside the genitals, and, when not, the membranes could be withdrawn from the vagina without introducing the finger into the canal. In this way the method became a part of the preventive antiseptic treatment. He placed the patient on the left side during delivery, but after the birth of the child she was turned on the back, which was the more convenient position in which to practice Credé's method, or, in case it should prove necessary to do so, to compress the aorta or make intraterrine injections.

Credé's originality in introducing this method had been questioned, but Dr. Garrigues had not been able to find that it had been previously described and practiced in all its details by any author.

The distinguishing features of Credé's method were:

1. That it was to be used in all cases.
2. That the uterus was to be grasped from all sides with both hands.
3. That the placenta was to be squeezed out by the outside pressure during a uterine contraction.
4. That the cord and placenta never were touched except in those rare cases in which the placenta was really adherent, and had to be peeled off from the uterine wall.
5. That the fingers were not introduced into the genital canal after delivery, at which time the danger of infection was much greater than before the passage of the child.

The advantages of this method were:

1. The certainty with which the end was accomplished.
2. The exact imitation of the natural processes.
3. The prevention of hæmorrhage.
4. The prevention of hour-glass contraction.
5. The prevention of inversion.
6. The prevention of avulsion of the cord or of the uterus itself.
7. The prevention of infection.

Dr. Garrigues thought it unnecessary to say anything about the old method of pulling on the cord, as it was attended by corresponding disadvantages. As to the let-alone method, by which no interference with the processes of nature whatever was made, not even removing the placenta when it lay loose in the vagina, a method practiced by some obstetricians in Germany, he thought there was nothing to be said in its favor. Of one hundred cases treated in this manner, it was recorded that in twenty-four the placenta came away within half an hour; in twenty in the second half-hour; in twenty-five in the second hour; in eleven in the third hour; in nine in the fourth; in five in the fifth; in three in the sixth; in two in the eighth, and in one in the twelfth hour. Behind the placenta blood-clot formed, in one case there was a decided foetid odor present, and in two hour-glass contraction took place. This method was not that of nature, as was alleged. The placenta was artificially prevented from coming out by keeping the patient lying on her back. It was presumable that in the natural state the woman

would, shortly after the birth of her child, get up and move about, and thus an opportunity would be given for the discharge of the placenta from the genital canal within a short time after the second stage of labor. Total expectancy, in his opinion, had many disadvantages and hardly any redeeming qualities. All savage tribes used massage and expression, and even the elephant, whose labor had been observed by Dr. Sussdorf, pressed its womb against a post in the ground.

Dr. A. S. HUNTER fully indorsed the conclusions given in the paper. He did not know that he could add anything to increase the appreciation of Credé's method, but he would suggest that it be begun just before the expulsion of the child. It had been his experience since he had adopted this course that the uterus had followed up its contraction firmly upon the placenta, and that the period between the expulsion of the child and that of the placenta had been very short. The amount of hæmorrhage which usually followed manual aid in the removal of the fœtus was, in his opinion, by this means much diminished.

Dr. A. HADDEN said that during twenty-five years of considerable obstetrical practice he had never lost sight of the importance of proper attention to the third stage of labor, and the results of his experience he thought abundantly proved the wisdom of that course. Out of the last thousand cases which he had attended, the statistics of which he had examined during the past few days, he found only one case of death from hæmorrhage. In that case there was purpura hæmorrhagica, and the patient died a few hours after the rupture of a very large varicose vein. In one case death occurred from paralysis of the diseased heart after a difficult labor; in one from rupture of the uterus; in one from an abscess a few weeks after childbirth. The practice which he had adopted for the removal of the placenta consisted partly in pressure upon the fundus of the uterus, or Credé's method, and partly in traction upon the cord. He always took pains to have the uterus firmly contracted and present a globular form, and he watched the patient an hour and a half after the expulsion of the placenta. He was a little skeptical about slight traction favoring inversion of the uterus. He had always practiced it, and had never known it to produce any such effect. He had had but one case in which partial inversion took place, and in that instance it had begun, as indicated by a hollow in the fundus, before anything was done toward removing the placenta. The attachment had been at the fundus, and not, as was usual, on the sides.

Dr. M. PUTNAM JACOBI thought there was no question but that Credé's method was the best for the removal of the placenta. She would only refer to two theoretical questions which had been suggested to her mind by the paper. As the completion of pregnancy approached, nature began to prepare for the throwing off of the uterine contents. This, she thought, was done by supplying increased arterial for venous circulation, for it was arterial blood which favored muscular contraction. The veins began to become closed by the formation of thrombi and the coagulation of blood within them. Credé's method tended to diminish the size of the uterine cavity and thereby to diminish the size of the veins and cause their obstruction by thrombi. The other theoretical suggestion was, that the construction of the placenta in the human female rendered her more liable to danger than the lower animals, and this fact might be one of nature's provisions against an over-increase of the population.

Dr. P. F. MUNDÉ had found Credé's method a very excellent one, and free from danger when carried out aright, but, when carried to too great an extent, or applied in a manner which the originator had not intended, it might cause too rapid expulsion of the placenta and favor inertia. He had found the best method to consist in making gentle compression with the hand

on the fundus of the uterus, beginning with the expulsion of the child's head, and continuing it until the uterus, which at first reached perhaps as high as the umbilicus, extended up no more than half that distance, and assumed a globular form, indicating that the placenta had become detached. In some instances it would be found that the placenta lay in the cervical canal after its detachment, in which case he would not hesitate to insert the whole hand, properly disinfected, and remove it. Care should be taken at the same time not to tear off the membranes. The placenta could not be expressed until it was detached, but the uterus could be made to contract by manipulations and detach the placenta, after which it could be expressed. He had met with the condition called encystment, in which the detached placenta was retained by the contracted cervix. He believed we should always remove retained membranes. He did not think harm would come from gentle traction upon the cord. He did not believe at all in the let-alone method.

Dr. J. H. FRUITHIGHT said, with regard to the let-alone policy, that the placenta should be looked upon as a foreign body, and he could not understand how any reasonable obstetrician could leave it in the genital canal longer than was absolutely necessary. He had not often used traction, but in one case, in which he made what he thought was gentle traction, the placenta separated in the central portion while the circumference was still attached, and it resulted in very troublesome concealed hemorrhage. He thought, as Dr. Mundé had suggested, that there might be some cases in which Credé's method would not be applicable, but the physician would be able to judge of such cases when he encountered them.

Dr. ISAAC E. TAYLOR looked upon everything connected with childbirth as physiological, and not as pathological, and he did not think that we ought to interfere with a normal physiological process. He did not believe he had introduced his hand into the uterus to extract the placenta more than six times during his entire practice. The uterus did not always look directly down into the pelvic cavity; its direction varied according to the attachment of the placenta. By making gentle traction upon the cord it could be determined whether it was attached to the posterior surface, to the fundus, or to the orifice. The physiological method of removing the placenta would be imitated by making gentle traction upon the cord, which would excite the fundus to contract upon the placenta and cause its expulsion. We should not use forced expression, supposing that the placenta ought to be expelled within five or ten minutes after the birth of the child. Nature's method was to wait twenty minutes, or even an hour. She was fatigued, and needed rest, and we should not compel her at once after delivery to renew her efforts to expel the placenta. He thought the placenta might be attached at such a portion of the uterine wall, for instance, at the opening of the Fallopian tube, that Credé's method would prove of no effect.

Dr. RAMSDELL said he was once called to see a patient whose physician had waited forty-eight hours, and the placenta was found to be retained on account of hour-glass contraction of the uterus. Septicæmia followed, and she died. He had practiced gentle traction with friction over the region of attachment of the placenta. Out of over seven hundred cases of confinement, he had but one death to record, and in that instance the nurse, contrary to his rules, gave vaginal injections for several days before he learned of the fact. In two or three cases he had been obliged to introduce the hand and tear off the placenta. As it was torn away it caused a sound like that of stripping the kidney of the hog from its fatty envelope. The placenta usually came away within twenty minutes; he did not believe it had ever been detained more than thirty minutes.

Dr. SELL had not practiced any method specially; formerly

he had waited from half to three quarters of an hour, according to the teaching of Dr. Taylor. In later years fifteen to twenty minutes embraced about the whole of the time from the birth of the child to the birth of the placenta. The method which he had practiced usually was about that recommended by Denman, before the introduction of Credé's method. But he did not think we need be governed by any absolute standard. It could not be too strongly impressed upon the young physician that he should not be in too great a hurry.

Dr. GARRIGUES, in closing the discussion, said he thought we should all agree that the physiological process should be imitated as far as possible, but there might be a difference of opinion as to what the physiological process was. To leave the placenta in the genital canal for some hours was certainly not natural. To make traction upon the cord he believed not to be a natural process, and he favored letting the cord alone; it would come away by gentle pressure. As to the case mentioned by Dr. Taylor, of attachment of the placenta around the Fallopian tube, it was probably a case of tubal pregnancy, in which the ovum afterward descended into the uterine cavity. Such cases were very rare, and could not have much bearing upon rules for so common a process as the removal of the placenta. He would not feel justified in introducing the hand into the womb to extract the afterbirth before the lapse of an hour and a half. On the other hand, he did not believe it was right to leave the placenta until it became decomposed.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Adjourned Meeting of April 7, 1884.

ALFRED C. POST, M. D., LL. D., Chairman *pro tem*.

REPORT ON INTESTINAL OBSTRUCTION, BY THE COMMITTEE ON THE COLLECTIVE INVESTIGATION OF DISEASE.—Dr. DAVID WEBSTER, the chairman of the committee, read a summary of the replies to the circular which had been distributed, and then read the histories of a number of the more interesting cases. Reports, more or less complete, of fifty-one cases had been sent in. In forty-seven there was total obstruction of the bowels, while in four it was incomplete. In twenty-four there was no stercoraceous vomiting. In one case there was no vomiting at all; only nausea. In two cases in which the vomited matter was not stercoraceous it had a gangrenous smell. In three there was not obstinate constipation. Twenty-one patients out of the fifty-one recovered. Out of nine cases in which the abdomen was opened, and constricting bands were found and divided, there were two recoveries, and there probably would have been a third but for imprudence on the part of the patient and his friends. The age of the patient was reported in thirty-one cases. Seven were five years of age or under; one was between five and ten; one between ten and twenty; eight were between twenty and thirty; five between thirty and forty; two between forty and fifty; six between fifty and sixty; and one was seventy-five years of age. Of those whose sex was reported, twenty-two were males and eight females. In sixteen cases the obstruction was demonstrated by operation or by autopsy. There were peritoneal adhesions in eleven cases; twists of the gut in two cases; stricture in one; invagination in one; and impacted feces in one.

Dr. T. H. BURCHARD had reported nine cases, seven of which were verified either by an autopsy or by an operation. They were all seen also by other physicians.

CASE I.—A bar-tender, aged twenty-nine, was taken with severe abdominal pain and distension, with obstinate constipation, followed by stercoraceous vomiting and great prostration. Death took place from collapse on the fourth day. At the autopsy there were signs of perito-

nit, with old peritoneal adhesions, stricture at the splenic flexure and upper half of the descending colon. The transverse colon was dilated.

CASE II.—A man, over sixty years of age, whose wife said he had always had a weak stomach and would swell up if he ate heavily, was accustomed to put his hand over the left side of his abdomen and say that all his trouble was there. The fatal attack began with pain over the umbilical and right hypochondriac regions. There was distension of the colon, with hiccough, vomiting, constipation, prostration, and a rapid pulse. There was stercoraceous vomiting. On the third day a single peritoneal band, two inches wide, binding down the descending colon and a small loop of the small intestine, was divided. Death from collapse took place eight hours afterward. There was no autopsy.

CASE III.—A woman, aged forty-two, had had peritonitis several years before. Her bowels were always constipated, and she was subject to distension from gas and violent attacks of flatulent colic. The attack began with great distension and distress, and attempts to relieve the distension were unavailing. There was vomiting, but not of stercoraceous matter. Death occurred within twenty hours, from heart-failure. At the autopsy some turbid fluid was found in the peritoneal cavity, also a few drops of pus on free surface of peritoneum, old peritoneal adhesions, and a cicatricial band binding down the duodenum about five inches below the head of the pancreas.

CASE IV.—A man, aged fifty-four, who had been in excellent health, whose bowels moved regularly every day, and who had had no previous history of intestinal or peritoneal trouble, was attacked, after four days of constipation, with pain in the shoulders and back. Vomiting, great distension, and symptoms of collapse set in, and there were persistent hiccough and vomiting four hours before death, but no stercoraceous vomiting. Aspiration of the bowel *per rectum* was attempted. Death took place from collapse twenty-nine hours after the severe symptoms set in. At the autopsy there were found commencing peritonitis and two old peritoneal adhesions, one seven inches long at the splenic flexure, and one five inches long at the hepatic flexure. The transverse colon was enormously distended with liquid feces which could not pass through the splenic stricture.

CASE V.—A patient, aged nineteen, who gave no previous history of peritonitis, but had been told by a physician always to keep the bowels free, was attacked with severe pain in the left hypochondriac region and slight constipation, and passed several days of abdominal distress and distension. Rapid aggravation of symptoms took place, with stercoraceous vomiting, and intestinal obstruction of an obscure nature was diagnosed. The abdomen was opened, and an adhesion was found binding down a portion of the jejunum to the transverse colon. The bowel was greatly congested. The stricture was divided with scissors, with strict antiseptic precautions, and the wound healed by first intention. The patient was ultimately cured.

CASE VI.—A man, fifty-five years old, whose previous health was fair, although he was dyspeptic and constipated, never had had peritonitis or any serious illness, but had been failing in health for about a year, his bowels becoming more and more constipated. He was taken suddenly with intense pain referred to the right hypochondriac region, and very marked distension of the ascending colon. There was a rapid development of acute general peritonitis, with collapse, but no stercoraceous vomiting. A diagnosis was made of peritonitis, probably with peritoneal adhesions binding down the colon at the hepatic flexure. No operation was done, on account of the collapse, and death took place on the fifth day. At the autopsy there were found signs of acute general peritonitis, with adhesions binding down the colon to the gall-bladder and liver; also a small cancerous nodule just beneath the adhesion.

CASE VII.—A man, of middle age, whose general health had been excellent, the bowels being regular as a rule. There was a sudden development of symptoms of intestinal obstruction, and a small umbilical hernia was suspected of being the cause of the trouble. Abdominal section being performed, the hernia was found not to be strangulated, but a short, circular band was found binding down the ileum to the meso-colon. The patient rallied well, but on the seventh day an imprudent friend gave him a bowl of oatmeal gruel. He vomited, peritonitis developed rapidly, and he died the same night. This was the case in which it was thought recovery might have taken place.

Dr. Webster then read from the reports of cases by Dr. A. B. ATHERTON, of New Brunswick, to whom one of the members of the society sent the circular. He reported four cases, in three of which he had operated.

CASE I.—A man, aged fifty-five, ate about a quart of choke-cherries. The next morning he suffered from colicky pain and vomiting. He was given castor-oil and other cathartics. When Dr. Atherton was called, the extremities were rather cold, and the pulse was small and feeble. A large enema of warm water was given through a long tube, but with no effect. Before he was called several movements had taken place, and quantities of cherry-stones had been discharged, with fecal matter. Laparotomy was performed, and a twist was found in the descending colon. By nicking a peritoneal band, Dr. Atherton was able to untwist the gut, when fecal matter passed readily. The bowels moved on the third day after the operation, and several times afterward; but on the fourth day some fecal matter was seen at the wound, and death occurred on the seventh day. There was no autopsy.

CASE II.—The patient was found to be suffering from peritonitis on the right side of the abdomen. He had had a somewhat similar attack the summer before. Under treatment the inflammatory symptoms subsided in about nine days, but a week later the patient was seized with pain in the abdomen again, accompanied with vomiting and eructations, no flatus passing downward. On the sixth day the abdomen was opened, and a band was divided of about the size of a crowquill, almost buried in the peritoneal coat, stretching across the gut just above the cæcum. Improvement took place almost immediately. About the tenth day the patient walked into an adjoining room, and a day or two later began to complain of pain in the right inguinal region, where there was a swelling. The swelling was hard and dull on percussion. For several months this swelling kept coming and going, and finally disappeared altogether. The patient for the past two years had been quite strong and well. In both these cases it had been necessary to puncture the gut in several places to let out gas in order to return it.

CASES III and IV.—In one of these cases no operation was performed, but in both an autopsy was made. In the first, the patient died soon after the operation. A constriction was found situated three feet and a half from the pyloric end of the stomach, which accounted for the absence of intestinal distension. In the second there was gangrene of the whole transverse colon, with a twist of the gut below that point, which could not be undone until it was cut.

In his remarks upon these cases Dr. Atherton said there was no question but that it was of the utmost importance that an operation should be undertaken as early as possible, after perhaps one or two attempts had been made to give relief by large enemata. But it should first be pretty certain that strangulation existed. The points he relied upon in diagnosis were: The sudden onset of the symptoms; the persistence of the eructations and vomiting; the non-passage of wind *per anum*, except where the occlusion was incomplete; the absence of the board-like feel of the abdominal walls, which was present in ordinary peritonitis; the occasional irregular form of the abdominal enlargement; in some cases, in which the strangulation was situated high in the small intestine, entire absence of distension of the abdomen; and, finally, stercoraceous vomiting after the second or third day. This symptom was apt to occur rather late, and therefore was not useful in early diagnosis. It was present in greater or less degree in all the cases reported, but only in the first was the stercoraceous character distinct. The previous history might throw light on the diagnosis. In all three of the cases of operation the incision was made below the umbilicus, near the median line, and Lister's precautions were used throughout.

Dr. B. A. CLEMENTS, of the army, reported three cases:

CASE I.—In this case there was no stercoraceous vomiting. There was inflammation at the caput coli, which had given rise to constriction of the ileum.

CASE II.—The patient was a lady who had a vaginal hernia due to a fall, a portion of small intestine coming down by the side of the *cul-de-sac*. For two years afterward she suffered at intervals of two weeks to six months from symptoms of strangulation, which were relieved within six to eight hours by opium. There was no stercoraceous vomiting or obstinate constipation. It was probable the symptoms were due in part to local peritonitis.

CASE III.—A man was taken with severe abdominal pain, enormous distension of the abdomen following, with stercoraceous vomiting. Warm water was injected into the bowel with a long tube, but it returned. The great distension was relieved somewhat with an exploring-needle. Dr. Clements's assistant practiced Simon's method of examination, and found the sigmoid flexure apparently twisted. The hand was passed up sixteen inches, and no further obstruction was met with. The patient died, and at the autopsy general peritonitis was found, with intestinal inflammation. At two points the ileum was gangrenous, and at these places the bowel was twisted. There was no twist or obstruction of the large intestine.

The CHAIRMAN had seen a considerable number of cases of intestinal obstruction, but had not kept a record of them. The obstruction had occurred in the course of hernia, stricture of the rectum, cancer, adventitious bands, etc.

Dr. WEBSTER read additional reports of cases, and others remained to be read, but, as there was other business to come before the meeting, on motion of Dr. H. G. PIFFARD, the further reading of the report was dispensed with, and it was ordered to be printed and circulated among the members, the discussion to take place at some future meeting.

THE COLLEGE OF MIDWIFERY.—Dr. PIFFARD said the impression had gone out through the medium of the "New York Medical Journal" that it was the duty of the Committee on Legislation of the Medical Society of the State of New York to take action to prevent the passage of a bill relating to the establishment of a certain college of midwifery in this city, and the regulation of the practice of midwifery in this State. That bill, as was well known, had many very objectionable features, and it was a duty of the profession to the public to have it defeated. But it was a mistake to suppose that the Committee on Legislation of the State society should assume this responsibility. That committee had too much to attend to already, and had not been furnished with means to enable it to assume and execute further work.

Dr. A. W. WARDEN offered the following preamble and resolutions:

Whereas, An effort is being made to incorporate, by act of Legislature, a private institution under the name and title of the College of Midwifery of the City of New York, asking that such proposed institution have the right to confer the degree of graduate of midwifery, and that such diploma be a license to practice midwifery in the State of New York; and,

Whereas, The bill to incorporate such institution is defective in many important respects, and the objects sought by such legislation are considered injurious to the interests of the people of the State of New York and the medical profession of the State; and,

Whereas, No opportunity has been afforded the medical profession of the State or the Medical Society of the County of New York to be heard in regard to the measure; therefore,

Resolved, That the Medical Society of the County of New York hereby petition the Assembly of the State of New York to defer action until such time as this society can be heard in opposition to such measure.

Resolved, That a copy of this resolution, signed by the President and Secretary of the Medical Society of the County of New York, be transmitted without delay to the Assembly of the State of New York.

In the discussion, Dr. T. H. MANLEY said that he supported the plan of licensing midwives on general principles, and the bill in question in particular. The records of the Bureau of Vital Statistics showed that one third of the women in New York were attended in confinement by midwives, and, that being the case, the midwives should be educated and the practice of midwifery regulated by law.

Dr. H. J. GARRIGUES said he was not opposed to this bill because he favored another; he was against anything tending to produce midwives. A hundred years ago the whole of obstetrical practice, in normal cases, was in the hands of midwives. Then doctors began to take hold of this kind of practice. From France the new system spread to England, where it met with very great opposition, but yet prevailed. It was long afterward that Germany was drawn into it, but now they were so far advanced in that country that in the larger cities ladies who could afford it were attended in confinement by physicians. Until now, the Scandinavian countries had employed midwives exclusively, but of late a discussion had begun there with the aim of substituting doctors. All this showed that there was a current running through all Europe in the direction of placing parturient women, so far as feasible, under the care of physicians, and the cause of that was that the midwives did not give satisfaction. Often irreparable evil had been done before the midwife sent for a doctor. The midwives were not only incompetent, but dishonest. Any honest doctor stitched up a torn perineum nowadays. The midwife never admitted that the perineum had been torn, and thus the germ of a long series of diseases was planted. Midwives were not progressive. Even a good midwife would be entirely behind the times after ten years, while every doctor read some kind of journal, by which he was enabled to keep pace with the improvements introduced into midwifery. Midwives were the greatest quacks. Besides confinement cases, they took gynecological cases, and dabbled in children's diseases and many other things which belonged to the domain of the physician.

A previous speaker had said that the midwives should be women with an ordinary English or German education, but the want of education was just the chief cause of complaint of them in Europe. The midwives were recruited from the lowest classes; they had no social standing, and were miserably paid. They were an evil, but they could not be dispensed with in Europe. Russia had only one physician for six thousand inhabitants; Germany one to two thousand. In the United States there was one for every six hundred, and in New York city one for every four hundred and eighty. Under such circumstances midwives were not necessary here. The United States presented greater facilities than any other country for women who wanted to study medicine, so that those who wanted to be attended by persons of their own sex might have female doctors. If, in much-governed Europe, the midwives gave so much trouble, how would it be here with our free institutions? In the proposed law there was not the slightest guarantee that the midwives would be taught well; the only thing that was sure was that their number would be increased.

Dr. DANIEL LEWIS said that, whatever might be our ideas regarding the propriety of regulating the practice of midwifery and the training of midwives, it was very evident that the bill before the Legislature was objectionable, and that the profession of this city, as represented by the society, should take steps to prevent its becoming a law.

The resolutions were adopted with only one dissenting vote.

Dr. PIFFARD moved that a committee be appointed to go to Albany to oppose the passage of the proposed law. The motion was adopted, and the President appointed Dr. A. W. WARDEN and Dr. H. J. GARRIGUES such committee.

MEDICAL SOCIETY OF THE COUNTY OF KINGS.

Meeting of March 18, 1884.

The President, Dr. JOHN A. McCORKLE, in the chair.

THE TREATMENT OF DIPHTHERIA AND CROUP BY LARGE DOSES OF BICHLORIDE OF MERCURY.—Dr. WILLIAM M. THALLON read a paper with this title. [See p. 401.]

Dr. G. G. HOPKINS had listened to the paper of Dr. Thallon with great interest, and, from the able and precise manner in which it had been presented, the principle laid down, in his opinion, was all the more dangerous. It was now some fifteen years since he first met his friend Dr. Prout in consultation over a case which had been under treatment by a late homœopath in the city of Brooklyn. It was a case of cystitis, and had been diagnosed as a case of spinal irritation. As a last resort, the doctor had administered bichloride of mercury freely, and the result was a profuse salivation. Since that time this speaker had been very much afraid of mercurials in frequently repeated doses, and he looked upon the present return to these frequent and free administrations as exceedingly dangerous. He believed that diphtheria could be treated successfully without mercurials. Several diphtheritic epidemics had been encountered by him, and he had never found it necessary to deviate from the stimulating plan of treatment. When he came to Brooklyn, stimulation was not in favor, but he was using it. Since then the treatment had become quite popular, and he was willing to compare the results of his stimulating treatment in diphtheria with those of any one in the city of Brooklyn. He had always found it work well. He had never had a case of paralysis following diphtheritic trouble, except of the fauces, and he had always administered stimulants. It was wonderful the amount of alcohol that these patients would tolerate. He recalled a case, occurring ten years ago, of a child eight months of age. He began with the administration of brandy, which he knew to be of the best quality, as the grandfather was a dealer and would, of course, furnish nothing but what was of first quality. He began by administering fifteen drops once in two hours. There was a diphtheritic membrane in the throat, and as the membrane increased the stimulation was increased, and *vice versa*. He finally, in this case, increased the dose to a teaspoonful once every hour. Then the membrane began to disappear, and in a short time it had vanished. He decreased the stimulant, and the membrane reappeared; increased the stimulant again, and the membrane entirely disappeared, and the child made a complete recovery. He did not remember the exact amount which was given, but it was very large. In the same street, the next year, he had another case in a young lady—a most severe case of diphtheria. When well, if that young lady were given a teaspoonful of brandy, she would be tipsy. She had never taken brandy before in any amount, but in this instance she took two tablespoonfuls of the best brandy every hour for a week. It was one of the most terrific cases of diphtheria that he had ever had to deal with. She made an entire and complete convalescence. He believed that in the use of brandy we had a treatment which was not dangerous. Mercurials had had a terrific history, and he thought great caution ought to be observed in their use. The profession ought to beware of their indiscriminate use. While he appreciated the paper read, yet he was glad to be present to protest against the use of bichloride of mercury in cases of diphtheria. He was not one of those who believed in the identity of croup and diphtheria. In diphtheria he deprecated the use of anything that depressed or debilitated the system. But in *true* croup it was the lesser of two evils, and his chief dependence was on mercurials. For the past three years tincture of the chloride

of iron was all that had been needed in most cases of diphtheria.

Dr. SAMUEL G. ARMOR, in commenting upon the paper, spoke of the care with which we should accept any new suggestions as to the treatment of diphtheria. If all the varied and boasted modes of treatment were collated, it would be one of the most curious chapters in all therapeutic literature; and doubtless much of the discrepancy grew out of experience based on entirely different types of the disease. Without accurate diagnosis, therapeutic suggestions were comparatively valueless. We recognized clinically the three types: simple, croupous, and malignant. He would not dwell on the characteristics of these. They were readily recognized. But the treatment of one of these types might be worse than useless in the others. Great reputations were often established in the treatment of the simpler varieties, which really require little or no treatment. In the more malignant variety a large number died under any kind of treatment. There were some points, however, in the excellent paper just read that were of peculiar interest—*first*, as to the remedy itself, and, *second*, as to the unusually large dose in which it was administered—a dose of the drug never heretofore recommended in any form of disease. The writer of the paper had alluded to Professor Pepper, of the University of Pennsylvania—an able, learned, and careful practitioner. It might be known to most of the members of this society that Professor Pepper read a paper before the American Medical Association some years ago, advocating the use of the bichloride of mercury in the relatively large doses recommended in this paper, and it might be of interest to the society to know how he came to thus use it. In a recent personal interview with Professor Pepper, he (Dr. Armor) had gathered from him the circumstances under which he came to use it in such apparently dangerous doses. The tolerance of such a dose was established by the merest accident—the blunder of a nurse. Dr. Pepper did not claim originality in its use. While attending a meeting of the State Medical Society of Pennsylvania, at Pittsburgh, a professional friend, whom he knew as a cautious and conservative man, read a paper detailing the use of the bichloride of mercury in the croupous forms of diphtheria in the large doses suggested in the paper of Dr. Thallon. Great success was claimed for the remedy. Amazed at the statements made in the paper, Dr. Pepper sought an interview with his friend, and learned from him that he stumbled upon the treatment by an accident of the blundering nurse referred to. In a severe epidemic of the disease he had been, like others, very unfortunate, losing a large percentage of his worst cases. Although discouraged, he still persevered with his quinine, muriated tincture of iron, chlorate of potash, etc., on one occasion prescribing these remedies every two hours, day and night. Within the first twenty-four hours, to his great surprise, his patient was better, the membrane was breaking up and sloughing off, and the child was in every respect better. During the next twenty-four hours it continued to improve, and now, for the first time, he learned from the nurse that the little patient, for forty-eight hours or more, had been taking by mistake a solution of the bichloride of mercury instead of the quinine and iron—the $\frac{1}{2}$ of a grain every two hours! It was to him a new revelation that such a dose, so oft repeated, had not destroyed the life of his patient, instead of curing his diphtheria! But, profiting by the blunder of the nurse, he prescribed the remedy in the same dose in other similar cases, and was gratified by the results obtained. He reported to the society over fifty cases thus treated, and with a success he had attained with no other remedy. Encouraged by the report of these cases, Professor Pepper, on the suggestion of his friend, had used the remedy with very gratifying results, but only, of course, in the *croupous variety*.

Dr. Armor had also used the remedy in the class of cases referred to, and, he was quite sure, with a success he had attained with no other remedy. In the more malignant varieties there was, of course, no substitute for quinine, stimulants, and alimentation, and he advocated the use of alcoholic stimulants at much shorter intervals than they are usually administered. In this connection, he alluded to the general action of mercury on the fluids and solids of the body. For a long time the general antiplastic action of mercury was taught by the schools and practiced by the profession. The profession had faith in it. Next to blood-letting, calomel and opium were regarded as the "sheet anchor" in the treatment of inflammatory conditions, especially in inflammatory conditions of serous and sero-fibrous structures. For a time the use of these agents was well-nigh universal, and we could readily understand that, in such extensive use, it was much abused. A reaction was natural. Finally, its antiplastic action was denied, and for the last ten or twenty years few practitioners had ventured to use mercury for this purpose. But a reaction was slowly taking place. The pendulum was swinging from one extreme to another. The younger members of the profession were finding, sometimes, as in this case, by merest accident, that the old doctrine as to the action of mercury in fibrous exudates was founded in fact. The drift of professional observation at the present time was certainly in that direction. In this connection Dr. Armor expressed the belief that in the background of these croupous exudates there was often a scrofulous diathesis. He had frequently observed that croupous children had fleshy or rather leucoplegmatic parents. There was a predominance of the adenoid element in one or the other parent. And this led him to remark on the use of small doses of mercury in the treatment of scrofulosis. Dr. Stokes attributed almost specific virtues to it in this class of cases; children often improved and fattened on it. At one time "Huxham's tincture of bark" with small doses of the bichloride of mercury was an exceedingly popular remedy, and it might be a question whether we had ever found anything better. A unique property of mercury, especially of the bichloride, in the estimation of Dr. Armor, was that it separated lowly vitalized from highly vitalized structures, and by this means relieved structures from lowly organized "cacoplastic" infiltrations. It drew the line of demarkation between healthy organized tissue and these diseased, lowly vitalized, and degenerate infiltrations—i. e., it rendered them capable of being acted upon by the absorbents. Hence its value in scrofulosis, and hence the fact so often observed that during its use there was a marked increase in the solids of the urine. In a case of croupous diphtheria with scrofulous diathesis recently treated by Dr. Armor with the bichloride of mercury in large doses, on the recovery of the child his attention was called by the mother to the fact that the scrofulous enlargement of the glands of the neck had disappeared with the diphtheria, a result probably due to the bichloride.

Dr. Armor further remarked upon the addition of small doses of the bichloride of mercury in combination with the chloride of ammonium in some forms of bronchial difficulty, especially in chronic cases in which the small divisions of the bronchi were loaded with a tough, viscid secretion, giving rise to combined dry and moist wheezing râles. He was quite confident that in many such cases it was a valuable addition at least to the chloride of ammonium, and tended to limit the peribronchial exudates that so frequently followed these catarrhal states of the mucous membrane. Finally, on the general question so well presented in the paper, Dr. Armor thought the bichloride of mercury was deserving of the attention of the profession. Other remedies of a stimulating and supporting character could be used at the same time as individual cases might

seem to require. In the more malignant forms, representing typhous states of the system, in which there was early and dangerous "blood poisoning," the profession would probably continue to rely on quinine, iron, chlorate of potash, and stimulants.

Dr. A. J. C. SKENE thought the merit of the paper depended on the fact that it only offered by way of suggestion this bichloride-of-mercury treatment as being possibly of value, and the suggestion was backed up by some clinical facts. One had a right to be somewhat skeptical when a remedy was presented for diphtheria which was said to be of infallible efficiency. But when the profession heard of something that promised good, it should at least claim attention; and therein he thought the merit of the paper lay. In the treatment of croup and diphtheria he had had some experience with this remedy, and he was of the opinion that either we had been entirely mistaken in regard to the doses of bichloride, or else a wonderful tolerance of the remedy had been established by diphtheria. He had used it in more cases than had been recorded in the paper—he had watched these carefully, and so far he had not seen the slightest harm arise. So far as his experience went, he was convinced that large doses could be given with perfect safety. Whether there was a tolerance of the remedy in these cases, or whether the profession had been mistaken in the dose, he was unable to say, because he had never given such doses to persons in health. With reference to the other method of treatment, in his medical childhood he might say he was brought up on whisky, in proof of which assertion it was enough for him to say that on his diploma he had the name of Dr. E. N. Chapman! If there ever was a man who taught others to use whisky in medicine, he was the man! He took all Dr. Chapman said regarding the use of stimulation as law, and he employed it faithfully in his practice. Still, he could not accept the challenge of Dr. Hopkins in regard to a comparison with the results of his alcoholic treatment. He could not, like the doctor, produce his cases in court, many of them having "joined the majority," yet he was satisfied that there were many cases where alcohol did a wonderful amount of good with reference to the bichloride as a depressing agent. He hoped the society had not forgotten the fact that the red globules were increased under its use. This had been demonstrated beyond doubt by Professor Keyes. His observations were made on syphilitic patients. Anæmic patients would also do better upon the bichloride than upon any other treatment. That bichloride was a dangerous remedy he thought was a mistake. He would like to take issue with Dr. Armor as to the use of the bichloride in malignant forms of diphtheria—conditions in which alcohol was demanded and called for. He saw no good reason why he might not employ it and at the same time give stimulants. He would not, with his experience, hesitate to use it in those malignant cases. He was perfectly sure of one thing—and that was that the results could not be very much worse than were obtained under the more fashionable modes of treatment. He thought there was no danger in a reasonable, rational use of the bichloride. Nor was it necessary to use it to the exclusion of other proper modes of treatment. If it aided us in any way, he was sure it would be of value. There was one point which he wished to call attention to, and that was that the bichloride treatment in many of the cases was not purely such. In most of the cases other remedies were used in conjunction therewith, so that it would be a little difficult to say to which one exclusively the benefit could be attributed. In the scarlatina case, eucalyptus was also given, but in such small doses that it was possible it had no effect. In conclusion, he would merely suggest that, while there was good evidence that mercury was of great value in croupous inflammations, there were also good reasons for giving it a full and fair trial in diphtheria. This could be done at last without danger.

Dr. HOPKINS wished to refer to one point in the remarks of Dr. Skene, and that was in relation to the use of bichloride in syphilitic disease. Would the doctor administer iodide of potassium in twenty-grain doses to a healthy person and expect the blood corpuscles to increase? They would increase if such dose was administered to syphilitic patients, but in healthy persons it would be otherwise. They would soon diminish in number.

Dr. SKENE, while he did not pretend to know much about syphilis, could take a chlorotic patient, anæmic, flabby, with pale mucous membranes, and a well-marked bruit, put her on the bichloride for a month or two with ordinary nourishment, and increase her red-blood globules and improve her condition markedly. Iodide of potassium would not increase the red-blood globules in a syphilitic patient, so that we must not pass the bichloride over the back of iodide of potassium. The bichloride would increase the red globules in tonic doses in syphilitic patients, and in patients free from syphilis. This fact was proved. The question had been raised at the time the observations of Keyes were made, and he thought it was fully demonstrated that the red-blood globules were actually increased by the use of bichloride, not only in syphilitic but in non-syphilitic patients.

Dr. G. H. ATKINSON remarked that something had been said about the action of mercury in syphilis, and, as he had more or less to say about this remedy in teaching, he desired to add his testimony in favor of using the remedy in some cases referred to in the paper. There was no doubt of the certain effect of the bichloride in plastic deposits of a low grade. The remedies he used most, however, were quinine, iron, and alcoholic stimulants, and, if any question arose about abandoning these, we had an opportunity to test the absolute value of bichloride, viz., in that class of cases where, after tracheotomy for croup, the disease (membrane) extended below the tube. Here, when all hope from medicine was abandoned, bichloride could be given a full trial, and, if successful, take its place in the list.

Dr. L. C. GRAY thought it very seldom that life was in danger in diphtheritic patients on account of the amount of exudation upon the mucous membrane. It was much more frequently the case that life was endangered from the great weakness which the disease induced; and the question had never fully occupied the minds of medical men as to what the cause of this weakness was. It was usually in no ratio with the fever present, and very often in no ratio with the amount of exudate. We were all familiar with cases where a very small amount of exudate and minute ulceration were accompanied by great prostration. The patient was within a day or two obliged to go to bed, and it took weeks for him to become strong and healthy again, and yet the thermometer might not range above 101° to 102°. Now, in a certain number of cases of diphtheria there occurred paralysis—a paralysis that, if it affected certain important nerves, as the pneumogastric or the spinal accessory, might end in sudden death. In every case where it affected the nerves it affected nerves of motion, terminating in motor paralysis. A sufficient number of these cases had been followed by autopsies and careful microscopic examinations, and it had been found that the pathological explanation was molecular disintegration of the great cells occupying the anterior or motor horns of the spinal cord. These cells were among the larger cells in the body, and it had been found that, when paralysis ensued in diphtheria, these cells were molecularly disintegrated. There was no effusion, no dilatation of vessels, no inflammation in the ordinary sense—simply this disintegration. The morphology of the cell was altered. It lost its shape. The nucleus, the nucleolus, the branching masses of protoplasm run-

ning off from the cell, *its processes*—all became involved in a more or less amorphous mass. Now, was it not a question whether this peculiar diphtheritic poison had not a predilection for these anterior-horn cells, causing in each case a motor weakness out of proportion to the thermometric record or exudate, and proceeding to well-marked cases of actual paralysis? It certainly seemed a very reasonable assumption to suppose it. There was certainly a close relationship between diphtheria-influences and the molecular disintegration of these anterior-horn cells. Now, if that was the pathology of diphtheria, there was nothing to show whether or not any known remedy had any effect, or what effect. Molecular disintegration of the anterior-horn cells constituted a very large group of diseases. It was the same in infantile paralysis. Many cases of adult motor paralysis were of the same group, also progressive muscular atrophy. In the light of these remarks, was there anything to show that quinine in small or large doses would arrest or in any way interfere with this fatal disintegration which was going to take place? In a disease like diphtheria, before a remedy could be especially relied upon there ought to be a much more careful study of the pathology than in the past. Every epidemic and endemic would vary in virulence; and who was to tell whether any set of cases belonged to the milder or the more virulent types, or whether this remedy should be milder or not? What record was there that would enable one to make a distinction between those cases having a fatal tendency and those that were modified by drugs? Until that was done, gentlemen might get up and sit down, and all they said after getting up would be but a mere expression of personal opinion in regard to the matter.

Dr. F. F. STUART had had but a limited experience in the use of bichloride in the treatment of diphtheria—three cases, with entirely satisfactory results. He had been very much pleased with the treatment. Dr. Atkinson's remarks reminded him of a case where tracheotomy had been performed in a case of diphtheritic croup. The membrane had extended down the trachea. A spray of the bichloride was used, and the membrane seemed to be dissolved. The patient, from the time the spray was used, made a rapid and entirely satisfactory recovery. Those who had done tracheotomy in these cases of croup, no matter what view of the pathology you might choose—whether there was a difference between the so-called membranous and diphtheritic croup or not—would recall some of the cases where the secretion of the bronchial tubes was thick, and where the tube was inserted the exudate was so thick as to clog it up, and, unless assistance was rendered, the life of the patient was greatly endangered. In such cases as these it seemed to him great benefit might be expected from the use of the bichloride spray. He was aware that the use of any spray, or even unmedicated steam, had a tendency to liquefy the bronchial secretions. But, at any rate, in future he would certainly use the bichloride spray. He had recently seen a medical work, popular about fifty years ago (Billing's "Principles of Medicine"), in which the *tonic* effects of the bichloride of mercury were spoken of. He (Dr. Billing) mentioned the use of bichloride in extremely small doses as a tonic.

Dr. B. F. WESTBROOK thought that Dr. Thallon was on the right track in endeavoring to find a remedy that would strike at the root of the evil. It should not be forgotten that, in the treatment of diphtheria, we were dealing with a malignant toxæmic disease—one of those diseases produced by the introduction of a poisonous germ into the body. The primary object of all our investigations should be to ascertain if there was any remedy which, by ordinary antiseptic, or a specific action upon the poison, would decompose it or antagonize it in such a manner as to obtund or entirely prevent the malignant influence

which it would otherwise exert upon the body. He believed, however, that Dr. Thallon, in making his calculations, had been overtaken by a very important fallacy—one the elimination of which would, in the opinion of the speaker, tend to overturn the theory that the bichloride of mercury had a neutralizing effect upon the diphtheritic poison, through its ordinary antiseptic properties—that is, of course, when given internally. He had not heard the first part of the paper, but he understood that the calculations were based upon the amount of antiseptic material that would be required to sterilize a given quantity of blood. The fallacy, he thought, lay in ignoring the fact that the blood was only one thirteenth of the body. The body was a succulent structure, made up of cells, blood, and other fluids. There was a constant interchange going on between the fluid in the vessels and that in the cells, processes of exudation and transudation, under the influence of the forces of osmose and capillarity. Any substance introduced into blood could not remain long in it exclusively, but must pass out into the cellular and intercellular structure. On this account it would be necessary, in order to conduct a sterilizing experiment successfully, to have a sufficient quantity of the antiseptic agent to act upon the entire body. That quantity, he thought, would be altogether too large to administer to a human being with safety. The body was made up of a collection of minute organisms. We were not individuals, except in the sense that we were, each one of us, an individual community made up of myriads of lesser individual members, each one of which was susceptible to the action of the germicide or antiseptic agent. A sufficient quantity to arrest a putrefactive process would, while it stopped the nutrition of the bacteria, also devitalize the cells and embalm the body, so that it would indeed no longer be affected by diphtheria, but at the same time would become a useless member of the body politic. It was possible, however, that, aside from the simple antiseptic action of the bichloride, it also possessed some specific power over this poison, as the cinchona salts did over the toxic agent of malaria. There seemed to be some doubt as yet whether the poison of diphtheria was a bacterial poison. The researches of pathologists had, so far, failed to identify any particular specific microscopic organism. Of course, a bacterium of diphtheria had been alleged, but, so far as the speaker knew, there was no means of identifying it and isolating it from the other organisms. Bacteria, particularly micrococci, were found in the bodies of diphtheritic patients, but whether they were the poison, or only acted as carriers of it, was hard to determine. In the further investigations which he hoped Dr. Thallon would make, this question ought to receive special attention.

In regard to the action of the bichloride, there seemed to be a diversity of opinion among the gentlemen who had used it. Professor Armor had referred to two kinds of diphtheria, croupous and malignant. The speaker did not understand what was meant by these terms. If by croupous was meant a diphtheria which involved the larynx and was not accompanied by severe constitutional manifestations, it might possibly be classed with ordinary inflammatory croup, and could be treated with bichloride or the other mercurials, iodide of potassium, pilocarpine, or any of the other well-known drugs. If, however, by croupous he referred to the form of membrane which was found on the surface of the mucous membrane, and which did not involve the latter to the extent observed in the other varieties, which could be removed without destroying the mucous membrane so as to produce hemorrhage, he thought it might be ruled out of the discussion, inasmuch as these mild forms were not the ones for which we were seeking a remedy. As to the nature of the diphtheritic process, there was no doubt that it was a constitutional affection. It was probable that the infected blood had

such an effect, in one way or another, upon the epithelium that it induced a coagulative necrosis—that is, a peculiar necrotic process in the cells analogous to the coagulation of albuminous fluids. This coagulating process solidified the cells, destroyed the nuclei, and welded them together into a homogeneous mass. The migration of leucocytes and accumulation of other substances helped to make up the false membrane. The depth to which the process went seemed to be the main anatomical distinction between croup and diphtheria. If the bichloride had the effect of liquefying or loosening such products as this, a part of its action might be readily explained. He believed that the view held by therapists was that mercury acted on abnormal deposits by producing some kind of soluble albuminate, which was absorbed and excreted from the body. In the case of a coagulative necrotic process in the substance of a mucous membrane, it might, by causing liquefaction of the deeper layers, favor the separation of the rest.

Another explanation might be found in its well-known action upon the glandular epithelium. It increased secretion. It was in this way that it softened the cough in bronchitis, increased the fluidity of the exudation in croup, etc. So, in diphtheria, by increasing the secretion of the mucous glands beneath the pseudo-membrane, it might loosen it and favor its expulsion. If it could be ascertained that it really had this effect in diphtheria, it would be a very valuable addition to our knowledge; but it should be remembered that this property was entirely different from an antiseptic one. It still remained to be demonstrated that, given internally, it had any general or specific antiseptic influence.

Dr. E. H. BARTLEY recalled the fact that children tolerated both the bichloride and the mild chloride of mercury in large doses. He had given both for days together, and the only perceptible effect was their action on the bowels; there was no salivation. He had seen children take a quarter of a grain of the mild chloride of mercury every three or four hours for some days and without evil effects. The idea of administering the bichloride of mercury as an antiseptic seemed to him mere nonsense, as, when the patient has a high temperature, over 100°, the mercury would be reduced to metallic mercury, or the oxide of mercury, in a short time. Experiments had proved that a large proportion of mercury was reduced to the metallic state, and was eliminated in that way. Of course, it was not all reduced, otherwise we could not get the peculiar effects of the various forms in the treatment of disease. That a large proportion was reduced could be demonstrated by placing a specimen of the contents of the duodenum under the microscope after its administration, when the characteristic globules might be observed. If such was the case, it could, in his opinion, be relied upon as an antiseptic agent for internal administration to a very great extent. It seemed to him that, in order to render the body aseptic, a sufficient quantity of the antiseptic material must be accumulated in the blood to antagonize the poison; and he did not see how material such as mercury could be made to meet the conditions. Alcohol was probably the only agent we had that could be administered in sufficient quantities to render the blood aseptic by accumulation, except possibly some of the benzoic or salicylic compounds. But, when we consider that the bichloride, when administered with other vehicles, as the elixir of bismuth, might be changed to oxychloride of bismuth and oxide of mercury, a compound not calculated upon, and that the bichloride was also decomposed in the alimentary canal, as he had stated, and its effects upon the peptones of the body, it was pretty clear that any attempt to administer a sufficient quantity to render the blood aseptic could not be successful. There might be a local effect upon the diphtheritic membrane, and probably some of the bichloride might be absorbed, and in

this way a beneficial action be experienced. In that way the spray-solution might be of benefit. When we gave a child, moreover, who was constantly struggling, and whom the nurse and all the family can not control, a spoonful of medicine, that medicine, by the time the operation of giving it was finished, was pretty well smeared over everything. If that medicine happened to be the 32d of a grain of the bichloride, he did not think that the child received very much benefit from it, except from its local antiseptic effect. If there was a certain amount absorbed, it entered the system in some mysterious way, but it could not remain as bichloride in the blood, and, if any antiseptic action was obtained, it was not from the bichloride. In regard to the manner of administering alcohol, the speaker thought it should not be given at the expense of rest. To wake a child up every quarter of an hour did not appear to him to comport with the principle of rest, for it was certain that the child was exhausted, and by that method of administration it was utterly impossible to give the child a sufficient quantity of rest.

Dr. CHARLES JEWETT asked whether the exudate which we sometimes noticed in the fauces of scarlet-fever patients indicated the presence of diphtheria.

Dr. WESTBROOK replied that he could not give a very positive answer to the question. From what was known of the two diseases, however, it was altogether probable that it did not. The scarlet-fever poison, it was well known, manifested a great predilection for the mucous membrane, particularly of the upper portion of the alimentary canal. One of its first effects was to set up an intense irritation of these membranes, accompanied by vomiting, red and heavily coated tongue, which afterward assumed a typically inflamed appearance, and erythema of the fauces and pharynx. When the disease was severe, the tonsils ulcerated and pseudo-membranes formed upon them. But this occurred during periods when diphtheria, as a distinct disease, was not prevalent, and in regions where no cases of diphtheria were observed. Epidemics of diphtheria also prevailed without a coincident increase of scarlet fever. The clinical history and the sequelæ of the two diseases were quite distinct, so that it could hardly be said that the presence of a false membrane on the fauces of a scarlatinal patient was evidence of the presence of diphtheria. It was the scarlatina anginosa, or scarlatina maligna of the old writers, and appeared to have prevailed independently of diphtheria epidemics.

Of course, it could not be denied that a scarlet-fever patient might also become infected with the diphtheritic poison, but the speaker believed that such combinations of different diseases were not common.

Dr. THALLOX, in concluding the debate, did not expect to say much, at the late hour reached, in reply to the various criticisms upon his paper. In the early part of the discussion the sentiment of the gentlemen speaking seemed to be in favor of the use of the bichloride in the first condition of croupous cases; that it was of great value in the inflammatory type. With that statement, all who took part in the discussion from a clinical standpoint seemed to agree. Regarding the criticisms of Dr. Hopkins, which were directed entirely to the last part of the paper, which dealt with malignant cases, he had taken great pains to state that the evidence that he had to offer was almost entirely concerned with the first type of the disease. The cases which he had related nearly all belonged to the first type. The second part of the paper contained a mere *suggestion*, to which he attached little value himself compared with the clinical evidence, but it had been taken up as if that were the main part of the paper. His friend, Dr. Westbrook, had said that he came in late and did not hear the first part of the paper, which might account for so much of the gentleman's criticism being wide of

the mark. He would not pretend to reply to the pathological sermon which had been preached, and he did not think it was worth while to spend much time in answering theoretical speculations of that sort. The same might be said in reference to Dr. Bartley's remarks. He did not intend to reply to them. Whether there was a changed condition of the bichloride according to the vehicle in which it was administered, or whether its chemical effects were local merely, mattered but little when it was evident that the medicine did good constitutionally. If we were to wait for clinical results, until the doctor could explain chemically the action of the remedies, before we accepted them as valuable, we had better stop the practice of medicine altogether. Therefore, because the doctor was unable to reduce the whole question to a formula counted for very little. In support of the treatment there was a vast mass of material. Cases had been given by members to-night and many others quoted, and the mere fact that we were or were not able to explain on chemical principles the matter under discussion did not invalidate such evidence. With reference to the use of the bichloride in malignant cases, he had but little experience, but that little and the reasons he had alleged were strongly in its favor. So far as the paper went, he thought it had served its purpose in drawing out the ideas of members as to the treatment in the first class of cases—i. e., membranous croup—and that was his object. He thanked the society for the manner in which his paper had been received.

Z. T. EMERY, M. D., *Secretary*.

NEW YORK PATHOLOGICAL SOCIETY.

Meeting of March 26, 1884.

GEORGE F. SHRADY, M. D., President, in the chair.

WEIGERT'S METHOD OF STAINING THE NERVES AND THE CENTRAL NERVOUS SYSTEM.—Dr. T. M. PRUDDEN presented some specimens of nerves and of the spinal cord, a part of which illustrated lesions of locomotor ataxia, stained with acid fuchsin, or the sulphate of rosaniline, after the method of Weigert, of Leipzig—a method which, although announced a year since, had not come into common use in this country, England, or even Germany. It was of special advantage in studying the nervous system. All the parts were alike stained red by the agent, but afterward, when treated with a dilute solution of caustic potash, the color was extracted from some of the elements sooner than from others. The axis-cylinders and parts of the myelin retained the color longer than other parts, and in some of the specimens presented they could be very distinctly seen as red lines standing out on a colorless background. The reagent had to be quite pure, and he had been unable to obtain any in this country which would answer the purpose, but it could be obtained of Dr. Grüber, 17 Dufour Street, Leipzig.

COLLOID CANCER OF THE PERITONEUM.—Dr. H. N. HEINEMAN presented the specimen on account of its great thickness and extent. The portion of peritoneum presented, which had undergone colloid degeneration, was more than two inches in thickness. The patient was forty years of age. There was no clinical history.

SACCUCLATED EMPYEMA; PNEUMOTHORAX.—Dr. HEINEMAN also presented a specimen removed from the body of a man forty-five years of age who died the evening before at Mt. Sinai Hospital, to which he had been admitted March 15th. His health began to fail a year ago; he suffered more or less from dyspnoea and cough, with slight expectoration. A short time previous to admission he was seized with shortness of breath, pain, muco-purulent expectoration, and a severe chill followed by sweating, and afterward almost regularly every afternoon

there was a rise of temperature, with sweating. The cough and dyspnoea increased. Health rapidly failed, and he was obliged to cease work. His physician treated him for pneumonia. After admission, the afternoon temperature during the remaining days of life varied between 102.5° and 104° F., the pulse was rapid, the respirations were from 48 to 50, and there was a lesser elevation of the morning temperature. He continued to grow weaker, three days before death oedema set in, and death took place from asthenia and oedema of the lungs. At the autopsy the pleura was found to be thickened and adherent, and on one side it inclosed two sacs, non-communicating and filled with pus, and there was another similar sac at the diaphragmatic portion. There seemed to be no channel by which the pus contained in the three separate cavities could have reached the bronchi. The other lung was emphysematous and the seat of chronic bronchitis. The heart was somewhat fatty, the aortic and mitral valves were thickened, and the kidneys were the seat of slight chronic diffuse nephritis. It would be interesting to know just how the pleuritic lesions took place. Dr. Heineman thought it probable the man had had empyema, and that it had tended toward recovery, but relapses had taken place and pus was inclosed between the adhesions, forming the cavities referred to.

Dr. E. G. JANEWAY had seen two similar cases during the present year. One had followed pneumonia. The house surgeon would draw off about four ounces of pus from one sac, and, failing to get more at that locality, would insert the needle at another point and draw off perhaps four ounces more, and in this way the presence of several distinct pleuritic sacs containing pus was demonstrated. A second case began with hydro-pneumothorax, and the patient finally recovered. In a third case, in which an autopsy was made the preceding week, hydro-pneumothorax had developed quite suddenly.

HORSE-SHOE KIDNEY, THE SEAT OF CHRONIC DIFFUSE NEPHRITIS.—Dr. F. FERGUSON presented the specimen, which was removed from the body of a man who was brought to the hospital on the 18th of January, with the statement that he had been suffering for three or four days with dyspnoea, and had been using opium for the last five years. At that time he was taking fifteen grains daily. At the time of his admission the dyspnoea was extreme; the urine contained thirty per cent. of the column of albumin.

CONGENITAL ABSENCE OF THE LEFT WING OF THE DIAPHRAGM.—Dr. FERGUSON presented the body of a colored infant from the morgue, showing absence of the diaphragm on the left side. The stomach, the left lobe of the liver, the greater part of the small intestine, and the caecum were all in the left pleural cavity. The left lung was not developed beyond the size of a hickory-nut, and was emphysematous. The right lung was well developed.

HEMORRHAGE INTO THE PONS.—Dr. FERGUSON also related the following case, and presented specimens: The patient was brought to the hospital by the ambulance on the 16th of March. He had worked out of doors. The friends said he had been paralyzed for twenty-four hours and had become comatose. The surface was dry, the muscles were relaxed, the pupils were equally contracted and irresponsive to light, and the bladder was distended with urine, which was withdrawn and was found to contain ten per cent. of albumin; the temperature was 100° F., the pulse was 80, the respiration was slow and stertorous. Pilocarpine and hot-air baths failed to produce diaphoresis. The patient became partially conscious. The reflexes were lost in the afternoon, and the patient died the same day. At the autopsy the ordinary lesions of chronic diffuse nephritis were found far advanced, and the condition of the heart invariably associated with chronic diffuse nephritis was present. A hemorrhage of considerable extent was found in the pons, which

had escaped into the fourth ventricle, completely filling and distending it with fluid blood. There had been no escape of blood into the subarachnoid space. It was only the second instance in which Dr. Ferguson had seen hemorrhage in this locality in cases of diffuse nephritis.

Dr. HEINEMAN recalled a case in which Dr. Alonzo Clark had diagnosed absence of a part of the diaphragm from the tympanitic resonance given by the intestines within the thoracic cavity, and from the coexistence of congenital heart disease.

Dr. R. W. AMIDON said that Dr. B. G. Wilder had presented the brain of a cat at the meeting of the American Neurological Association, in 1883, in which there was absence of the corpus callosum, and had referred to the case of a man in whom there was a similar abnormality, but of whom it had only been recorded that he was very profane and quarrelsome.

Dr. JANEWAY said, in reference to the fourth specimen, that it was commonly noted in books on diagnosis that the presence of albumin in the urine was one of the evidences of coma due to uremia. As a matter of fact, however, it was quite common to find albuminuria in cases of cerebral hemorrhage.

CHRONIC PROLIFERATIVE PERITONITIS.—Dr. L. H. SAYRE presented the specimen for Dr. L. A. SAYRE, and read the history. The patient was sixty-six years of age, a large and robust man, always healthy until 1876, when he suffered from a severe attack of double pleuro-pneumonia, after which he was never entirely well. Two years after he fell and sustained a severe concussion of the spine, which was followed by complete temporary paralysis of the lower extremities and of the bladder. In 1879 he fell again from a hammock, and afterward suffered from intense pain across the stomach, extending over the abdomen, and indicating acute peritonitis. For the remaining six years of his life he took daily hypodermic injections of morphine to relieve pain. Swelling of the limbs and ascites developed, and he was tapped one hundred and eighty-seven times and large quantities of fluid were drawn off, amounting, in all, to 1,203 $\frac{1}{4}$ pounds. Only once or twice was a trace of albumin found in the urine. The quantity of urine passed daily since 1879 had gradually diminished from year to year, until during the last forty-eight hours of life it amounted only to seven ounces, and the patient died of uræmia. Dr. Welch made the post-mortem and microscopic examinations, and, in addition to the lesions of peritonitis, found lesions in the heart, pericardium, lungs, pleura, liver, spleen, kidneys, and bladder, and atheromatous degeneration of the arteries. The brain and cord were not examined.

DIPHTHERITIC DYSENTERY FOLLOWING CONFINEMENT.—Dr. JANEWAY presented a large intestine the whole length of which was involved by diphtheritic inflammation, probably of not more than four days' duration. The interesting feature of the case was that it should have happened just after confinement. The woman was twenty-three years of age, a domestic, who was delivered of her first child on March 18th, at 6 P. M., labor being normal and lasting six hours. The temperature on the following morning was 99° F., and remained at that point until the afternoon of the second day, when it suddenly went up to 104.4°. And the uterus, which had contracted well after delivery, increased to a large size, extended above the umbilicus, and was flabby. There was a discharge from the vagina, somewhat colored, which was increased by pressure upon the uterus. There was no perceptible odor. Intra-uterine douches of bichloride solution, 1 to 2,000, were given when the temperature rose. On the night of the 22d she had a number of diarrhoeal movements, perhaps eight. These were afterward controlled by suppositories of opium. On the last day of her life, although the temperature continued high and the heart-beat was comparatively strong, there was no pulse at the ankle or wrist, and the hands were cold. She had taken full, but not

excessive, doses of ergot. She had had morphine, whisky, and quinine. At the autopsy there was found to be some diphtheritic endometritis, with some patches on the vagina, but the lesions were not so striking in the genital tract as in the large intestine. There were no other lesions except slight parenchymatous nephritis and a large, soft spleen. The case was interesting, as it demonstrated that in some of these cases the intra-uterine injections would not touch all the disease. In this case the lesions in the intestine had the appearance of being older than those in the uterus. It was further interesting as illustrating a point which Dr. Janeway had frequently remarked, namely, that simple inspection of the discharges would not always enable us to determine the absence of a serious diarrhoeal disease; and, even should a little blood or a few clots be found in the stools after delivery, they might readily be attributed to the lochia.

TUBERCULAR PLEURISY.—Dr. JANEWAY also presented a specimen removed from a patient who had suffered from tubercular pleurisy, with absence of tubercles in the lungs and other portions of the body. There was also hypertrophy with dilatation of the left ventricle, caused by aortic regurgitation, and the usual sound accompanying that lesion was preceded by a louder sound heard at a higher point, due to the blood passing over the calcareous and roughened valves.

DEATH FROM PERITONITIS FOLLOWING PERFORATION OF THE APPENDIX VERMIFORMIS.—Dr. J. LEWIS SMITH presented a specimen with the following history: On March 16th he was called to a woman of about twenty-five years, fleshy, and of robust appearance, a seamstress, who, for two or three months preceding the attack, had complained of a dull, aching pain low in the abdomen on the right side, and in the pelvis. At the time of his visit the pain had suddenly become more severe, and it extended over the entire abdomen, but the tenderness, though general over the abdominal cavity, was most severe in its lower part, especially on the right side, in the iliac region. She complained that the pain extended even to the right shoulder. With these grave symptoms he was surprised to find the temperature, taken under the tongue, normal, and the pulse not accelerated. The respiration was normal. There was no appreciable meteorism or distension of the abdomen, but it was unusually hard on pressure. She had no vomiting and no diarrhoea. A large poultice of flaxseed and mustard was applied over the abdomen, and sulphate of morphine was directed to be given every three hours, or oftener if needed for the pain, in quarter-grain doses.

On the following day the symptoms remained about the same. The temperature, taken under the tongue, was still not elevated. On the third day she stated that she had vomited occasionally, the temperature was elevated, but not more than two or two and a half degrees, and subsequently it did not rise above 102.5° F. The pulse was about 100. Her monthly flow had now begun, which was about one week before the usual time. Its early appearance was attributed to the poulticing. She stated that similar pains had always accompanied her catamenia, though perhaps less severe.

Her features now began to show more serious sickness than at first, and the doctor became anxious as to the result, so that she was visited twice daily, though he was not apprehensive of her immediate death. It seemed to him that she had inflammation in the region of the right ovary, with some surrounding peritonitis, and he thought of perforation of the appendix vermiformis, but was not prepared to accept the diagnosis of a general peritonitis from the history of the case and the symptoms. The flow of blood continued, and the patient remained about the same, with occasional vomiting and the aspect of more serious sickness than at first, till the afternoon of the sixth day,

when she suddenly went into collapse and died. The physician who saw her at this time, in the absence of Dr. Smith, believed that she had sustained an internal rupture of some kind.

Autopsy, twenty-three hours after death.—The body had been surrounded by ice. There was no appreciable meteorism, or distension of the abdomen; the abdominal walls were thick from fat. On opening the abdominal cavity, very fetid pus escaped, filling the room with the offensive odor. General recent peritonitis was found, with agglutination of the intestines. The peritoneum was of a pink color, and readily stripped from the intestines. The inflammatory lesions were most marked in the right iliac region, and in this locality, extending down into the pelvis and reaching the ovary, the walls of an abscess could be made out, especially on the parietal surface of the peritoneum. The appendix vermiformis, curled around so as to lie against the cæcum, was of about the size of the little finger, of a slate-color, as were also adjacent parts, probably from long contact with pus, and firm or solid to the feel from infiltration. Near its middle was a perforation large enough to allow a slate-pencil to pass. On account of the offensive odor of the pus, the foreign body was not searched for. The uterus was not opened, but it was normal in size and appearance.

It seemed evident, from the lesions and the history, that some foreign body had lodged in the appendix, probably three, perhaps four months before death, and that when this body, by ulceration, had reached the peritoneal covering of the appendix, perityphlitis occurred, producing the abscess. Rupture of the abscess and escape of fetid pus and the foreign body into the abdominal cavity caused the fatal peritonitis. Usually peritonitis, when acute and general, could be diagnosed readily, but in some instances, as in the present, a clear and certain diagnosis was not readily made. Dr. Smith had once attended a young woman in her confinement who, immediately after the birth of the child, had intense general peritonitis, of which she died in a few days. At the autopsy it was found that a similar abscess, produced by the perforation of the appendix by a baked bean, had ruptured. Were such a case, without an autopsy, reported nowadays at any of our medical meetings, it would undoubtedly be said that the patient died of septic peritonitis, and the neglect to wash out the uterine cavity would be deplored.

It appeared, from the history of this case and those of others, that in a considerable proportion of instances perforation of the appendix did not cause immediate death, but gave rise to perityphlitis and an abscess, which, so long as it did not rupture into the peritoneal cavity, was not fatal. If the physician were consulted before the abscess broke, it seemed probable that he might, as a rule, save the life of the patient by opening it externally. Life had, in one instance that had been reported to him, been saved in this way.

Dr. FERGUSON had seen a case in which the extremity of the appendix was necrotic.

Dr. W. M. CARPENTER asked Dr. Ferguson if there were old adhesions which held the vermiform appendix in an abnormal position in his cases.

Dr. FERGUSON said there were only such adhesions as belonged to the last sickness.

Dr. CARPENTER remarked that the late Dr. Krackowizer had advanced the view that in most, if not all, cases of perityphlitic abscess, with perforation of the vermiform appendix, there had occurred a peritonitis, perhaps early in life, which resulted in fastening the appendix in an abnormal position that favored patency of its opening from the mucous membrane, and hence rendered it especially liable to receive foreign bodies traversing the alimentary canal. He had been unable to confirm the statement by autopsies made at Bellevue.

Dr. JANEWAY said it was a mistake to suppose that the vermaform appendix, the seat of a foreign body, always became perforated very easily. He had seen one case in which it had become distended to the size of a child's head, and in another to that of a Bologna sausage.

Miscellany.

THERAPEUTICAL NOTES.—*Sulphate of Iron in the Treatment of Hemorrhoids and Proctocoele.*—Dr. Samuel Wimpelberg writes to the "Medical Bulletin" that he has had more favorable results with the persulphate of iron in the treatment of hemorrhoids than with any other drug in the pharmacopoeia. He recommends an ointment of the subsulphate, in the proportion of twelve grains to the ounce, to be applied night and morning. In cases of proctocoele, he uses the persalt internally, in doses of two grains three times a day, in conjunction with the local use of the ointment. He speaks particularly of the rapidity with which he has known piles to disappear under this treatment during pregnancy.

The Action of Salicylate of Sodium on the Uterus.—According to the "Bulletin général de thérapeutique," M. Balette has arrived at the following conclusions in regard to the action of salicylate of sodium on the uterus: In ordinary therapeutical doses, it allays the pains of dysmenorrhœa, probably by its sedative action on the central nervous system. It appears to promote the menstrual flow, and, in some cases, to provoke its reappearance. In four instances, given in large doses, it was followed by abortion, but moderate doses seem to have no tendency to act as an abortifacient. No oxytocic effect was ever observed in experiments on animals. Nevertheless, the caution is added that it should never be given during gestation, except on very precise indications, and that then its action should be watched carefully.

The Physiological Action of Paraldehyde.—At a recent meeting of the Paris *Société de biologie* ("Gazette hebdomadaire de médecine et de chirurgie," March 21, 1884), M. Hénoque gave an account of some of the results of his experiments with this agent on animals. He insisted particularly on the decided reduction of the interchange of material produced by it in the tissues, accompanied by a notable and rapid lowering of the temperature, slowing of the respiration, and diminution of the oxy-hæmoglobin in the blood. These effects, he considers, furnish an explanation of its retarding and even arresting the action of certain poisons, such as nitrite of sodium and strychnine, without the need of supposing that any real antagonism exists between them, as has been maintained in the case of strychnine.

The Salts of Lead in the Treatment of Erysipelas.—Several letters having lately been written to the "Lancet" concerning the use of white lead in the treatment of erysipelas, Mr. J. H. G. Drummond, of Manchester, writes to that journal that he has made free use of a preparation termed "Wilson's linimentum plumbi lactatis compositum," which, he intimates, contains the albuminate and the salicylate of lead. On these constituents, he thinks, the efficiency of the preparation as a surgical dressing largely depends. He has always found it successful in erysipelas, and, although he has applied it to extensive surfaces, he has never known toxic symptoms to arise.

THE MISSISSIPPI STATE MEDICAL ASSOCIATION met at West Point on Wednesday, the 2d inst.

THE ASSOCIATION OF AMERICAN MEDICAL EDITORS will hold its annual meeting in Washington, May 5th, at 8 P. M., in Medical Hall, Southeast corner of Sixth and F Streets. The Annual Address will be delivered by President Leartus Connor, M. D., on "The American Medical Journal of the Future, as Indicated by the History of American Medical Journals in the Past." Dr. N. S. Davis will open the discussion on "How far can Legislation Aid in Elevating the Standard of Medical Education in this Country?" in which Dr. A. B. Palmer, Dr. Henry O. Marcy, Dr. L. S. McMurtry, Dr. C. H. Hughes, Dr. Frank Woodbury,

Dr. William Brodie, Dr. A. N. Bell, Dr. William E. Atkinson, Dr. W. C. Wile, Dr. W. R. D. Blackwood, Dr. Henry Leffmann, and Dr. Deering J. Roberts will take part. All members of the profession, especially journalists and authors, are invited to be present and take part in the meeting.

[Signed.]

JOHN V. SHOEMAKER, M. D., Secretary.

THE NEW YORK NEUROLOGICAL SOCIETY held its annual meeting Tuesday evening, the 1st inst., and the following-named gentlemen were elected officers for the ensuing year: Dr. W. J. Morton, president; Dr. C. L. Dana, first vice-president; Dr. R. W. Walsley, second vice-president; Dr. E. C. Wendt, recording secretary; Dr. W. M. Leszynsky, corresponding secretary; Dr. E. C. Harwood, treasurer; Dr. E. C. Seguin, Dr. L. Weber, Dr. T. A. McBride, Dr. G. M. Hammond, and Dr. W. R. Birdsall, councillors.

THE ILLINOIS STATE BOARD OF HEALTH will hold its regular quarterly meeting at the Grand Pacific Hotel in Chicago, beginning Thursday, April 17th. At this session candidates for certificates will be examined, both non-graduates, who must undergo an examination upon their preliminary education as well as in the usual branches of medical study, and also graduates of colleges which have not fully complied with the schedule of minimum requirements adopted by the board in 1880, and in force from and after the session of 1882-'83.

A NEW TEST OF WATER PURITY.—Dr. Angus Smith, F. R. S., reports to the Local Government Board, as one of the inspectors under the Rivers Pollution Prevention Act, that in all natural waters sugar ferments and hydrogen gas is given off, the proportion varying with the organic impurity of the water. The proportion of hydrogen evolved will prove a quantitative test of the virulence of the microbes present in the waters.—*Medical Times and Gazette.*

A LITTLE KNOWLEDGE.—A candidate at a recent examination for a scholarship under the School Board is reported to have made the following statement concerning the process of digestion: "The food passes through the liver, and evaporates by means of little holes called capillaries." The examiner who published the answers suggests that this novel theory had its origin in the study of some cheap diagram of the digestive system. Knowledge of this kind is indeed a dangerous thing, and worse than conscious ignorance. There is a simple ignorance, and there is a compound ignorance—that is, there are people who are ignorant and know that they are, and there are people who are ignorant and think they know. The latter only are a dangerous class.—*British Medical Journal.*

FOOD FOR THE WORKING MAN.—The Paris correspondent of the "British Medical Journal" (February 28, 1884) says: M. George, in a lecture "On Food for the Working Man," given at the Conservatoire des Arts et Métiers, stated that, in 1841, when the railway from Rouen to Paris was constructed, the English employed on it did more work than the French. The authorities, on inquiry, ascertained that the English workmen were fed principally upon meat, and the French principally on vegetables. The French were consequently put on the same diet, and achieved more work than their neighbors. M. George impressed upon his audience the necessity that working men should eat "butchers' meat," not pork. He recommended horse-flesh. By means of a magic lantern, M. George showed representations of a series of edible animals, and indicated the best and most healthy portions for working men's food.

TOXIC ACTION OF COPPER.—It seems to grow more and more doubtful whether copper can be reckoned among the poisonous metals. Of course, in large quantities it is noxious; but this is true of alcohol and of many other compounds, which can not fairly be considered as poisons. The latest experiments tend to indicate that, at any rate, copper is not a cumulative poison, like lead. MM. Houllès and De Pietra Santa, in a recent communication addressed to the Académie des Sciences of Paris, report that they have been unable to discover any injurious action on the health of the workmen engaged in the copper industry, and have come to the conclusion that the so-called "colique de cuivre," asserted in the eighteenth century to be a definite disease, does not exist.—*Lancet.*

Original Communications.

SUPER-ALIMENTATION, ARTIFICIAL ALIMENTATION AND GAVAGE, AND THE EMPLOYMENT OF ALIMENTARY POWDERS, ACCORDING TO THE METHOD OF DR. DEBOVE.*

By HENRY B. MILLARD, A. M., M. D.,

MEMBER OF THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK; VICE-PRESIDENT OF THE NEW YORK MEDICO-CHIRURGICAL SOCIETY; HONORARY MEMBER OF THE SOCIÉTÉ ANATOMIQUE DE PARIS, ETC.

THE system of treatment of numerous chronic diseases by the method indicated in the foregoing title, as introduced and practiced by Dr. Debove, of Paris, has become in the medical world, of that city at least, a subject of great interest. Except in France, however, no full exposition of it has been published, and such *excerpts* as have appeared have been so meager as to give but a faint idea of its character.

In 1882, while I was in Paris, some of the medical friends of Dr. Debove gave me an account of the remarkable effects of his treatment, which seemed to me at the time a little exaggerated. I had made an appointment to visit the Bicêtre with him for the purpose of observing the practical working and results of his system, but was prevented from keeping it. I was more fortunate last summer, and passed considerable time with Dr. Debove at la Pitié, where he was then on duty, in examining patients treated by him by artificial and super-alimentation, taking notes of their histories, etc. I had then his own explanation of his method, the preparations of the powder used, etc., amplified by later interviews and correspondence; and, as I have since employed his system to a considerable extent, I look upon it as a duty to present to my medical brethren at home a brief exposition of what I consider a most valuable addition to the therapeutic art. Although since leaving Paris I have perused everything, I believe, likely to be of importance upon this subject, still, had not my own experience been favorable, I should perhaps not be inclined to write upon the subject.

The essential features of Dr. Debove's system may be mentioned as:

Artificial alimentation, by the œsophageal sound (*gavage*).

Super-alimentation, or alimentation by considerable doses of aliment, which, according to Debove, can be effected only by the sound, and

Lavage (washing or rinsing the stomach).

In papers read before the Société Médicale des Hôpitaux, in November, 1881, and April, 1882, upon the treatment of pulmonary phthisis by forced alimentation and upon the subject which constitutes the title of this paper, Dr. Debove presented his theories relative thereto, illustrating them by numerous cases of hospital patients who had been treated with benefit. Dr. Amanieux, of Paris, published in

1883 an elaborate thesis upon the direct administration of the powder of beef.* The "Bulletin général de thérapeutique" of May, 30, 1882, contains an interesting article by Dr. Dujardin-Beaumetz on the use of powdered beef, and Dr. Broca contributed to the "Progrès médical" in 1882 a series of articles upon *lavage* of the stomach; and the same year the thesis of Robin, on alimentary powders and artificial alimentation, was published. These by no means include all the literature of this subject, but they are among the most important publications.

The comprehension of the utility of artificial and super-alimentation involves the recognition of some commonplace facts—namely: that certain diseases destroy by inanition; that without the constant formation in a certain abundance of the products of assimilation to replace wasted elements and tissues, life can not be sustained; and that in many ailments where life is waning there is often a duplex condition of inanition and disease of such a character as to make it difficult to discriminate whether it be inanition or the disease which is destroying the patient, and which it is that is keeping up the other.

"Inanition," says Chossat, "is the cause of death which marches abreast of and in silence with every malady in which alimentation is not in a normal state; it reaches its term sometimes sooner, sometimes later, than the disease it accompanies, and may become a principal disease where at first it had been only an epiphenomenon."

In pathological conditions, as well as in functional derangements, the appetite may undergo a variety of disturbances, from simple anorexia and nausea to vomiting upon the prehension of food. The two former, though comparatively unimportant when transient, become of grave importance when they persist and can not be overcome.

"Anorexia is not," says Debove, "a banal phenomenon, but a deplorable complication which enfeebles the patient and delivers him, so to speak, without defense, to his malady. Often it is the cause of the disease, it has preceded it, prepared for it a favorable soil, and, the malady existing, it contributes to its maintenance. We often see hysterical subjects seized with disgust for all food, unable to take it in more than insignificant amount, despite the advice of the physician and their own efforts. I have already seen such patients die thus from inanition. Last year I was consulted by the family of a young girl, eighteen years of age, who had taken for several months, and that with difficulty, only a few grammes of nourishment daily. She was reduced almost to a skeleton, without any special lesion of any organ. This appeared to me a case where I should advise artificial alimentation; the parents, however, were frightened at the idea of introducing the sound, and my urgent representations could not change their ideas. The patient continued to refrain from food, and two months later, complaining of greater weakness than usual, with vertigo, was taken with syncope, and died without suffering."

Debove also treated last winter an hysterical woman whose symptoms were of a very serious character, especially spasm of the pharynx. For several months she scarcely ate,

* Read before the New York Medico-Chirurgical Society, March 11, 1884.

* "De la poudre de viande, son administration directe. Ses effets."

and her debility was extreme. It became necessary to introduce food by the sound, progressively increasing the dose. The patient improved visibly, and when at last she had gained sufficiently in weight, and her color had returned, the hysterical symptoms (not the *hysteria*) disappeared.

"Anorexia," says the same author, "is not a phenomenon special to hysterical subjects, it may be observed in a great number of patients; it prepares the ground for various diseases, and notably for tuberculosis. If it is not absolute, if the alimentation is simply insufficient, the physician is less struck by the relation of cause and effect; I know a number of tubercular cases having such an origin. These facts have not escaped authors, but they have interpreted them in a different manner, usually considering that the constitutional malady, still latent, has caused the anorexia; often, according to my own observations, the inverse pathogenesis is to be admitted.

"It is necessary, then, to watch with care the appetite of patients, to insist on their overcoming their disgust for food, and, should this be insurmountable, to resort to artificial alimentation. This method of treatment is applicable in cases of vomiting so frequent as to threaten the patient with inanition, or at least to alter profoundly the general health. Cases of vomiting called 'nervous' are often met with in the hysteric, in which the pathogenesis is very obscure; in consumptives vomiting often occurs, attributed (wrongly, in my opinion) to a mechanical cause, as the compression of the stomach by the diaphragm from paroxysms of cough; both these kinds of vomiting are usually amenable to artificial alimentation."

That the vomiting in phthisis after paroxysms of violent cough is not simply mechanical is shown by the fact that, after food has been artificially introduced into the stomach by the sound, violent spasms of coughing, sufficient to extricate large quantities of mucus, do not dislodge the food.

"Such is the series of arguments which led to the idea of forced alimentation. I admit them to be theoretical, but scientific results are seldom to be obtained, except by the aid of theories one is seeking to verify.

"Super-alimentation differs from artificial alimentation: by the former we propose to nourish the patient, and to prevent the disastrous results of anorexia, or vomiting; in the latter, to introduce into the economy considerable quantities of food, and to increase organic combustion."

Anticipating somewhat at this point the description of aliments used by Dr. Debove, I would mention that the powder of the muscular fiber of beef is usually employed by him, being mixed with milk or hot water, so as to be of about the consistence of cream. Upon the excellence of the powder employed, and its proper preparation when administered, depends, most of all, the success of the treatment.

Other aliments than the powder of beef may be given by the sound, as eggs in beef-tea, milk, etc.

Debove was led to the invention or preparation of powdered beef by the difficulty he experienced in making other articles of nutriment pass through the sound.

The two methods of administration consist in direct alimentation and forced alimentation, by the former method the food being given as any other food would be, with cer-

tain precautions and restrictions; by the latter, the food being introduced into the stomach by the esophageal tube, or sound, this being employed when anorexia, nausea, or vomiting exists to such an extent that nourishment can not otherwise be taken.

The class of ailments to which these methods are suitable are those characterized by emaciation from non-assimilation of food, chronic diarrhœas, nausea, and vomiting, unless dependent on organic diseases of the stomach, and sometimes even then; the vomiting of pregnancy, chlorosis, and anemia, nervous maladies dependent on these, and in various conditions of exhaustion—as after acute illnesses, hæmorrhages, etc.—and, above all, phthisis pulmonalis. I have seen in Paris, and in my own practice at home, all these conditions relieved and cured.

Dr. Debove states that under the influence of super-alimentation—

1. Sweatings cease.
2. Cough and expectoration diminish and then disappear.
3. Patients gain in weight.
4. The strength returns.
5. Physical signs are modified; the signs due to pulmonary indurations or cavities subside, while those dependent on pulmonary secretions disappear. In cases of phthisis far advanced, with pulmonary lesions, the most that can be hoped for is that life may be prolonged. In acute and galloping consumption this treatment is useless. Fever is a contraindication, unless it come on in evening exacerbations.

Debove compares tuberculosis to plants that grow in a certain soil; the soil modified and enriched, other parasitic plants may grow, but they will be different from those that flourished when the soil was not enriched. Dr. Debove, it should be mentioned, is a firm believer in the bacillar origin of tuberculosis. (His lectures upon this at la Pitié, recently published,* are of great interest.) "I may say," says this author, "that by super-alimentation we give our patients strength to resist their malady; and our idea here may be rendered clear by this comparison: when the vine is attacked by the phylloxera, one of the best remedies is to manure the ground well. The parasite is not destroyed, but the plant is endowed with strength to support its harmful action. Super-alimentation is the inverse process of that by which a great number of subjects become tuberculous. It has been for a long time recognized that the cause of phthisis with many subjects is insufficient alimentation, and that this in its turn is of a character positive or relative, as poverty, excess of any kind, diabetes, lactation, etc."

Here, as I shall refer to cases in which artificial alimentation has been employed, I will describe the manner in which it is used. Dr. Debove employs for the introduction of the mixture into the stomach a soft elastic tube, about three quarters of an inch in diameter, and having at the bottom two fenestræ; this part of the tube is twenty-two inches in length, and, although flexible, is of sufficient

* "Leçons cliniques et thérapeutiques sur la tuberculose parasitaire," Paris, 1884.

firminess to introduce easily; at the opposite extremity from that which enters the stomach there is a joint, and the tube after this is of a softer consistence, this part being thirty-nine inches long and terminating in a funnel-like expansion; into this end a large glass funnel is placed, into which the liquid is poured. This tube is a modification by Debove of Faucher's, who invented it in 1878. It may also be used for rinsing the stomach (*lavage*), the principles and methods of which will be given in another place. It can also be used as a stomach-pump, as it acts on the principle of the siphon, and is free from the danger of sucking in the mucous membrane, to which the ordinary stomach-pump is liable. I can not speak too highly of this beautifully contrived tube. It is easy of introduction, it can be used in cases of poisoning, and is the best long elastic tube I have seen for deep injections into the bowel.

The patient, sitting up or recumbent, throws back the head, the mouth wide open; the rounded extremity of the tube is placed behind the larynx and pushed down the œsophagus, the patient at the same moment being asked to make an effort to swallow; the sound introduced into the œsophagus, the joint will be, in an adult, in the mouth. This part of the operation is, the first two or three times, disagreeable enough and may produce retching, threatening to displace the tube. It is necessary to await the subsidence of the nausea before introducing the alimentary mixture. To do this, the funnel is inserted into the extremity of the tube, a little above the head of the patient, if he is sitting up; if lying down, about a metre above the level of the bed; the mixture is then gently poured in. When this has completely entered the stomach the tube is slowly withdrawn. This part of the operation is sometimes, at the commencement of the treatment, accompanied by the rejection of a small quantity of the food; this accident does not occur after a few *séances*, when the sensitiveness of the pharynx is diminished. In withdrawing the sound, not only the funnel but the tube must be entirely empty, as otherwise a few drops of the mixture might enter the larynx. It is not necessary to lubricate the sound before its introduction; it is sufficient to wet it in any liquid, as milk or water. After the third or fourth trial the patient is usually able to introduce the tube, swallowing it up to the joint—the mixture, of course, being poured in by another person.

As regards the danger of accidents from *gavage*, they should not occur; difficulties there sometimes will be. The size of the sound would make its entrance into the larynx by no means easy, still the possibility of this should be taken into consideration. The greatest difficulty usually experienced, aside from the existence of strictures or organic changes, is from spasmodic closure of the pharynx or œsophagus. In such a case force must not be used; the sound must be patiently withdrawn and its reintroduction attempted. Should the spasm persist, which does not often occur, however, the attempt should be deferred.

Debove recommends, after the funnel has been emptied, to pour briskly into it a small quantity of water or milk, to prevent adhesion of any of the food to the tube. Though the quantity be small, if it be lost several times daily it is

of importance, when it is considered that the powder represents four times its weight in beef.

"The question is often asked," says Debove, "if the sound is indispensable, and if super-alimentation can not be employed without it. It seems to me impossible to obtain super-alimentation, continued a sufficient length of time, if one simply forces the patient to *eat*; and precious time is thereby lost."

As I shall show hereafter, the powder can, I think, in most cases be administered *directly*, but not usually in such full doses as when it is given by the sound.

The first case in which Debove employed his method was that of a patient at the Bicêtre, with symptoms of advanced tuberculosis, with large cavities, profuse night sweats, great emaciation, and such weakness that he could sit up but a few hours. Whenever he attempted to eat he was seized with violent nausea, followed by vomiting and cough. The only food he could take was a glass of milk. "I introduced," says Debove, "by the sound, October 1st, a litre of milk, first having washed out the stomach. It was perfectly tolerated, there being neither nausea nor diarrhœa. Afterward, encouraged by this experience, we increased the ration, using the sound twice a day, in these two times administering two litres of milk, two hundred grammes of finely minced raw beef, and ten eggs.

"Digestion was performed well, as there was no diarrhœa, and the perfectly clear liquid which ran out after each rinsing showed the stomach to be acting well. Another proof that the food was being digested and absorbed was that the patient increased in weight on an average ninety-two grammes a day.

"The treatment was followed by other effects no less remarkable; the profuse sweatings ceased; he had suffered from insomnia, and sleep returned and strength was restored to such an extent that our patient, who had remained all day in or near his bed, and who easily lost his breath, could now rapidly ascend two flights of steps of the infirmary, and walk outside a great part of each day. Expectoration was diminished, and the physical signs improved; the cavities underwent no change, but the bronchial râles, diffused throughout the chest, diminished. The results in this case were too favorable for me not to employ the treatment in other cases.

"The second case was one of phthisis, in a much less advanced stage than the first. There were some crepitant râles at the apices of the lungs, especially the left; patient coughed much, had night sweats; no appetite, taking with difficulty a little broth. Forced alimentation, without *lavage*, was resorted to. In a few days it became possible to introduce by the sound, daily, in two doses, 200 grammes of beef, with ten eggs and two litres of milk. There were no untoward results. The average daily gain in weight for twenty days was 192 grammes; the sweats ceased, sleep and strength returned, and the patient could take a long walk without shortness of breath. Râles diminished. At the end of twenty-one days the daily average of urea excreted had increased from 16 to 34 grammes.

"The condition of the third patient was still more unfavorable. He was in the last stage of pulmonary phthisis;

there were large caverns in both lungs, tubercular laryngitis, and an uncontrollable diarrhœa, which had existed for several months. This patient was subjected to the same regimen as the others, except that bouillon was given instead of milk. There was, however, an average loss of weight of 50 grammes daily, though it may have been greater previously.

"In spite of the deplorable state of the patient, many important phenomena were modified: the sweating ceased, sleep returned, and the diarrhœa which had existed for months improved greatly, diarrhœic stools occurring only every three or four days.* Urea increased from 16 to an average of 27 grammes daily.

"One phenomenon especially was observed in each of the three patients. They experienced the sensation of hunger, complained when the sound was not introduced at the usual hour; and this return of appetite led me to hope that the treatment might soon be suspended; the anorexia occurring most easily in patients who have sunk below a certain level, the general health improved, this tends to disappear."

The utility of artificial alimentation was discovered, as it were, accidentally by Debove. He first resorted to it in a case of phthisis with vomiting, because the patient could be nourished in no other way, and, upon augmenting progressively the dose of the food, was surprised to find nearly all the morbid phenomena improve in an unexpected manner.

The benefits resulting from the treatment are evident; they followed close upon it, the patients had been for a long time previously in the hospital under Dr. Debove, and they were not of that class of cases that, coming to a hospital, having been badly nourished, lodged, and clothed, experience a steady improvement from hospital diet. Frequently, in autopsies after death from pulmonary phthisis, lesions so extensive as to be necessarily incurable are often met with. Nevertheless, the lesions cicatrized, and the caseous products eliminated, there may remain a sufficient respiratory surface. The important practical point is not the intensity of the affection at a certain point, but the extent of the lesion. Whatever the condition of the apices may be, if the two lower thirds of the lung respire sufficiently there are many chances of success.

(To be continued.)

MEMORIAL SKETCH OF THE LIFE

OF

J. MARION SIMS, M. D.

By W. GILL WYLIE, M. D.

(Concluded from page 408.)

The first anniversary of the Woman's Hospital was held at Astor Place, January, 1856. It had proved a great success, the lady managers saw the necessity of a larger hospital, and steps were taken to get a charter from the State. Dr. Sims says: "The charter of the Woman's Hospital of the State of New York was obtained in 1857. The Hon. James Beckman was my chief adviser and

* It should be stated that a full dose of subnitrate of bismuth was added to the food.

coadjutor. I spent a great deal of time at Albany that winter, neglecting my private business very much, and leaving Dr. Emmet in charge of the hospital. . . ." He also says: "The most difficult thing and work I have ever achieved in connection with the founding of this Woman's Hospital was the procuring of the land on which the building stands to-day. . . . This I accomplished after a great deal of hard work and political wire-pulling."

In 1856 he had fully recovered his strength and worked steadily at the hospital, and had a large private practice to attend to. In 1861 he went to Europe for the first time. He says: "It was in June that I went, because I needed a little holiday; I had worked too hard, and was tired out; but I went more particularly to investigate the hospital treatment in the Old World."

He first went to Dublin, and there operated upon a patient with vesico-vaginal fistula before Dr. Fleetwood Churchill and others. From there he went to Edinburgh to see Sir James Y. Simpson; he was especially interested in seeing Simpson operate for dysmenorrhœa, but did not think it well done, and formed an unfavorable opinion of the man. Of Mr. Syme he writes: "I saw him operate repeatedly. I have seen great surgeons operate all over the world, operating in my own country, in London and Paris, but I have never seen such operating as his, or such an operator as Syme." He went to London and operated before Spencer Wells and others; the patient died in six days, the first that he had ever lost from this operation. The autopsy showed that the sutures had closed the ureters. He went to Paris in September, 1861. There no one had yet successfully closed a vesico-vaginal fistula. Dr. Johnston introduced him, and soon he was invited to operate by Hugier at the Beaujon, and Nélaton and others were present. Then he operated for Vernier at the St. Louis Hospital. Both cases were successful, and it created a sensation. He also operated successfully for Loguier at the Hôtel Dieu. Soon after this he was invited by Velpeau to go to La Charité and operate on a young woman who had been the subject, so it was said, of seventeen previous operations by Jobert de Lamballes. This case succeeded, making four in succession.

Soon after this he was called to Brussels to operate in the hospitals there. Dr. Sims says: "I then returned to Paris, and was on the eve of going to Vienna, there to show the operation. I forgot to mention the fact that about three or four years before I went to Paris an American surgeon had gone there claiming to have been the author of the operation for vesico-vaginal fistula, and he gave me some credit for having initiated the work, but claimed my speculum and all the instruments as his own. He had set the blade of the speculum at a little more of an acute angle with the handle, and he had put an ivory handle to the tenaculum instead of ebony. He used what was called a button for fastening the silver wire. He had operated only once in Paris. The operation was only a partial success, for very soon after the sutures were removed there was an absorption of the line of union, and the fistula opened and the urine escaped; so his operation was pronounced a failure." A case of vesico-vaginal fistula in a

woman about forty years old, who had been subject to this infirmity for more than twenty years, was brought to Dr. Sims. "She had been seen and examined by many of the leading surgeons of Paris, and pronounced incurable. She had also been seen by the American surgeon who preceded me to Paris three years previously, and who had refused to operate upon her." Dr. Sims hired rooms for her and operated on her in the presence of Nélaton, Velpeau, Civilale, Bonn, Leroy, Sir Joseph Olliffe, Campbell, Hugier, and others. Dr. Johnston gave the anæsthetic. The operation lasted one hour. In one week's time the sutures were removed, being about twelve in number, and the patient was perfectly cured.

Just as he was getting ready to go to Vienna, M. Nélaton sent for him to see a case with him. The patient was brought to Paris; she needed preparatory treatment, and detained the doctor so long in Paris that he did not go to Vienna. This was the celebrated case where Nélaton resuscitated the patient from the influence of chloroform by hanging her head down.

He writes: "Soon after M. Nélaton's case was perfectly cured I returned to America, . . . arriving in New York on the 11th of January, 1862. When I left home, in July previously, there was marshaling of forces North and South for the great civil war. On my arrival in Europe we heard of the battle of Bull Run. On my return I was obliged to provide myself with a passport to come into my own country. When I got home I found that we were in the very midst of a great civil war, and I was made so unhappy by the state of affairs then existing that I made up my mind to take my family abroad, and we sailed from New York in the *Great Eastern* in July, 1862. My programme was to establish my family in Paris, where I thought I would remain six months in the year, in the summer time, and then return home and practice my profession to make money to support them abroad. I was so sure of coming back again to America in the autumn that I had paid for a return ticket on the *Great Eastern*; but, as soon as I got to Paris, I found that the work I had done there the summer before in the hospitals and for M. Nélaton had given me so much reputation that I had no trouble at all in getting business enough to support my family without the necessity of returning to New York for that purpose." He was consulted by many of the nobility. "Thus I was detained abroad quite unexpectedly, but, viewing the political condition of the country and the disturbed state of affairs, I easily resigned myself to the force of circumstances and remained abroad, thinking every year that I would return."

When he began writing his book it was in 1863, while he was at Baden-Baden, where he was attending Lady Hamilton. He fully intended to write a complete work, but changed his mind and commenced a pamphlet on "Sterility." He says: "I went on with the subject, and, instead of its ending in a pamphlet form, it was a book on all the diseases of women, leaving out the subjects of ovariectomy and the accidents of parturition, but embracing everything else in the department of gynaecology. This book was entitled 'Clinical Notes of Uterine Surgery.' It was so radical and revolutionary in all the methods adopted, and so startling in

the results claimed in the treatment of many affections, that the profession did not at first readily accept its teachings; but in a few years it has revolutionized completely the subject of gynaecology, and now it is received everywhere as authority. Before that day and time there was not a professorship of gynaecology worthy of the name connected with any of our medical schools, and now we have professorships of this department in every medical school in the country; and, indeed, throughout the civilized world. I have always said this book was a mere accident, that I never intended to write it, and the book that I went to Baden to write has never yet been written." He remained abroad until 1868, spending most of the time in Paris and London. He performed many operations, and his reputation was as great throughout Europe as it was in his own country. Dr. Sims was a true American, and a believer in the republic. In September, 1868, he returned to New York and took an office at 13 East Twenty-eighth Street, and soon had a large practice. On December 7, 1868, he read a paper "On the Microscope as an Aid in the Diagnosis and Treatment of Sterility," which was afterward published in the "New York Medical Journal."

He remained here for the winter, visited his family in the summer of 1869, and returned to New York in the fall.

In 1870 he took part in organizing the "Anglo-American Ambulance Corps for service in the Franco-Prussian War." He was made its chief.

During the winter 1871-'72 the Medical Board of the Woman's Hospital of the State of New York was reorganized. It would have been an easy matter for Dr. Sims to divide the service with Dr. Emmet, but he believed that it was for the interest of the hospital to add other prominent men to the staff, and it was finally settled by appointing Dr. J. Marion Sims, Dr. Thomas Addis Emmet, Dr. T. Gaillard Thomas, and Dr. E. R. Peaslee.

The beds of the hospital were divided between these four, each having sixteen beds, and they went on duty May 1, 1872. The writer first met Dr. Marion Sims in 1868. At that time he was fifty-five years old, but he was as erect, as active, and as young in heart and mind as a man of thirty-five or forty. My father and mother knew Dr. Sims as a boy, and he could tell me about my mother when she was an infant in arms. And I could tell him of the old campus grounds of South Carolina College, from which I had just graduated. His house was always open to me, but our real acquaintance began in May, 1872, when I came before the Medical Board of the New York State Woman's Hospital as a candidate for the position of interne. Before this the place was had by appointment without competitive examination. I was senior assistant in 1872-'73, when the trouble began which a year later ended by Dr. Sims resigning his position. The hospital was crowded with patients, and its increased fame drew many visiting doctors to the clinics, and many patients with desperate cases applied for treatment. Among the latter were a large number with cancer. At that time the use of antiseptics was not so well understood, and some of these patients, when tamponed after being curetted, occasionally caused offensive odors in the wards. The lady managers believed this would injure the hospital, so they urged

the Board of Governors to pass a by-law prohibiting the admission of cancer cases to the hospital. This some of the Medical Board thought was rather high-handed, and maintained that the medical men of the hospital were the proper ones to decide what patients should be admitted. On account of the crowds of doctors coming to the clinics, the governors passed another by-law allowing only fifteen medical visitors to attend each clinic, and the Medical Board protested against this regulation. At the annual meeting these by-laws were under discussion, and Dr. Sims read a protest and said that unless these by-laws were rescinded he would resign his position as a member of the Medical Board, and he afterward sent in his resignation and it was accepted.

About this time Dr. Sims was the subject of very harsh criticism, and much was said about his rash and reckless operating. His operation for division of the cervix uteri for the relief of dysmenorrhœa and sterility and the great danger in using his so-called sharp curettes were especially commented upon and condemned. During my hospital service of eighteen months I saw much of the doctor, and, after leaving the hospital, was frequently at his house, and often assisted him at operations, but he rarely said anything about his relations with the hospital, and, as was his habit, he rarely made any other than complimentary statements about members of the profession. If he did say anything, he was frank and intense, but, until the open rupture of friendly relations took place between him and his former associates in the Medical Board, he never uttered a word against them, nor would he allow others to do so in his presence. Others did talk indiscreetly and unjustly, but not Dr. Sims. He was too much of a man. He was totally incapable of an under-handed trick. No one who knew him could doubt his courage and his frankness. Neither fear nor selfish policy ever seemed to me to influence him. If he made mistakes, they were honestly made. He had the moral courage, that few men possess, to acknowledge a wrong even in the midst of an excited discussion. His convictions were strong, his feelings intense, and he was very impulsive, but behind these was a noble-hearted and chivalrous nature. It was not he that first brought the matter before the public. It came about in this way. Mr. Henri Stuart, already referred to as having rendered Dr. Sims invaluable aid and advice in starting the Woman's Hospital, wrote a biographical sketch of Dr. Sims and sent it to two medical journals for publication: one the "Virginia Medical Monthly," the other the "New York Eclectic Medical Journal." That published in the "Virginia Medical Monthly," of January, 1877, was revised by Dr. Sims, and all reference to the cause of his resignation from the Woman's Hospital was, at his request, left out. But that published in the "Eclectic Journal" was printed without Dr. Sims's knowledge or consent. It was this article which led to the unfortunate controversy that followed.

Dr. Sims was very decided about anything which he had once taken time to master, but he was as a little child about all matters out of his special work. He was conscious of what he did not know, and for that reason all the more certain and convinced as to what he did know. What he did, he did well. He was always prompt to the minute.

He hurried in going to or getting at his work, but he never hurried in the performance of it. He did not hesitate, but he was deliberate, exact, and threw his whole being into whatever he did. It was marvelous to see the quick, impulsive, playful man settle down to deliberate, exact, unerring work with his instruments. Of all the letters that I have ever seen of his, only one admitted "haste," and not one showed evidence of it. They were always plainly and neatly written, and clearly stated.

It was his consciousness of what he did not know, together with a sincere desire to do well all that he did do, that prevented him from writing more than he did.

In 1872 he wrote an article on "Septicemia in Ovariectomy," published in the "New York Medical Journal," December, 1872, and April, 1873.

On February 6, 1874, he read a paper at Albany before the State Medical Society on "Intra-uterine Fibroids," which was published in the "New York Medical Journal" of April, 1874; and in 1874 he addressed a meeting at Steinway Hall on "The Discovery of Anaesthesia," and later in 1874 he wrote a paper giving Dr. C. W. Long the credit of being the first to give ether and do a surgical operation while the patient was under its influence.

In 1875 he was elected president of the American Medical Association, and delivered an address "On the Prevention and Regulation of Syphilis in America," and in his farewell address at Philadelphia he came out boldly on the code question.

He always lent a willing ear to an enthusiast, and was ready to give any one the credit of meaning right. He knew what it was to be looked upon as an innovator. A plausible story enlisted his sympathy, and many an unworthy person has received both money and encouragement from him. He was too much occupied with his special work to study human nature closely, and he was naturally inclined to credit every one with honest intentions.

In 1877 he decided to go abroad. His reasons were twofold: First, his work here in New York was more disturbing and exacting than his work in Europe, and he got better fees and was not so much overrun with charity cases in Europe. He wanted to complete his book, and it was nearly impossible for him to work steadily while here. He had much more leisure abroad. Second, he wished to start his son alone, in order to make him self-reliant by throwing him entirely on his own resources. He settled Dr. H. Marion-Sims in San Francisco, and subsequently sailed with the rest of his family for Europe.

Before leaving he turned over his business here in New York to me. He returned to New York in 1879, and for a year's time I was with him constantly. He had an immense practice, operating on something over a hundred cases in private practice in a year.

While abroad he became a convert to complete Listerism, excepting the spray, and this he allowed me to use.

One of the three deaths in his practice during that year was that caused by the use of bromide of ethyl, which he reported in a paper before the Academy of Medicine.

He wrote a paper on the "Treatment of Stenosis of the Cervix Uteri," and it was published in the "Am. Gyn.

Trans.," vol. iii, 1878; and in the "American Journal of Obstetrics" for July, 1879, he published his views on "The Treatment of Epithelioma of the Cervix Uteri."

In 1880 his son, Dr. Harry Marion-Sims, returned from California and entered into practice with his father.

Dr. Sims was elected president of the American Gynecological Society in 1880. In December, 1880, Dr. Sims, when tired out from constant work late in the afternoon, gave his seat in his brougham to two ladies, and mounted the box with the driver and rode thus some distance. This little act of gallantry was like Dr. Sims, but very unusual and, in such weather, very imprudent for a man of sixty-nine years. It undoubtedly was the exciting cause that lighted up an attack of pneumonia which nearly cost him his life. Up to this time his physical elasticity and activity were extraordinary for one of his age. And his mind was so receptive and progressive—in other words, so fresh and active—that his last teachings seem to be only fully appreciated by the younger men of the profession. Many that took up his early teachings and made good use of them had passed the age of receptivity before Dr. Sims had finished furnishing new ideas and new instruments, which was up to within a few days of his death.

During the first six weeks of his severe illness I was in constant attendance. For ten days he was in a typhoid and semi-delirious state. For him it was a fearful struggle. He never could bear pain well, but he had no fear of death. He said repeatedly: "If I had my book finished and a few notes of my life written out, I would be ready to die." His mind was so active that it helped to exhaust him. It was wonderful to see how completely the special work of his life, his ambition, absorbed his whole nature. In his delirium he was constantly contriving instruments and going through with operations. He was very willful and difficult to manage. He had often said to me: "Wylie, I have an iron will," and I saw that he was right. If ever a man did have completely the courage of his convictions it was J. Marion Sims. He did not have much faith in drugs, and often we could not make him take them. Even in his delirium he fought against them, and imagined that certain persons were trying to poison him. He willingly took nourishment. For weeks his left lung was completely solidified; but his heart stood the strain, and surprised both Dr. Metcalfe and Dr. Loomis; the latter visited him daily. About the 1st of February, 1881, his temperature, which had never remained any length of time near normal, began to rise steadily higher and higher every evening, and it was plain that in this climate he would not live much longer. We waited for a change for the better in the weather, but it did not come. With his temperature at 102° F., and the weather thermometer at 20°, we took him South. After leaving Washington, every mile that we traveled seemed to improve him, and when he reached Charleston, in his native State, we felt sure that he would get well. His recovery was slow, and, although he never was the same man physically, yet in a year's time he looked well, and was again at work.

He returned North still quite feeble, and went abroad in June.

While abroad he did some work in practice, but spent

the winter in the south of France. He did some writing, but was too feeble to work as usual.

In September, 1882, he came home, much improved in health. His digestion was poor, and he complained of severe pain about his heart. While in San Francisco, in 1877, he had what may have been one or two mild attacks of angina, but they were not repeated. He was examined both abroad and at home by the best experts, but none could find positive indications of organic disease of the heart. We all thought the trouble was functional, or perhaps, in a measure, due to old adhesion about the pericardium, for it had been affected when he had pneumonia.

He was positive that he had serious disease of the heart, and it often caused deep mental depression.

Notwithstanding his poor health, he delivered his paper on "Treatment of Gunshot Wounds of the Abdomen" at the New York Academy of Medicine, and for three quarters of an hour held a crowded house spell-bound by his eloquence and masterly treatment of the subject.

As the weather grew cold in November he went abroad, and spent most of the winter in Rome, where he had a most successful practice among the nobility of Italy. He returned home July 13, 1883. He had regained his flesh and color, but still complained very much of his heart. During the summer he was busy writing his autobiography. In September he came to town, and, with his son, Dr. H. Marion-Sims, was busy at work seeing patients and operating, but he could not do much work without great fatigue, and to us who knew him he was greatly changed.

He intended to sail for Europe early in November, but was persuaded to remain over a week longer to do a very serious operation. On November 13th, at 9 p. m., he went with his son, Dr. H. Marion-Sims, to see this patient. On his return home he coughed considerably, and, after taking some morphine to check it, went to bed. He had a habit of writing down ideas at night, by means of a pamphlet, the edge being placed on paper so as to guide his pencil without a light. At 3 a. m. he was writing in this way, sat up to take some water, and fell back and expired without uttering a word. An autopsy showed that he died of atheromatous degeneration of the coronary arteries.

He was truly master of himself. Vices he had none, not even of the smallest kind. The animal in him was completely under control. His habits and his appetites were always guided by his reason. I have known him, day after day and month after month, rise at seven, take a simple breakfast, consisting of a glass of milk and Southern hominy, bread and butter, and sometimes an egg. At eight enter his carriage, and make a few morning calls on severe cases. At nine return to his office and see patients till one or one thirty; and take a simple lunch of steak, potatoes, etc. At two enter his carriage, visit patients, operate, etc., returning home usually about five or six, write letters, and at seven take a plain dinner of one kind of meat and vegetables. He never took wine nor coffee nor tea, nor condiments of any kind. At the table he was usually talkative and playful, talking about the topics of the day, the theatre, of which he was very fond, etc. After dinner he usually wrote letters and did light work, reading journals, etc., or passed his

time with his family or friends in the drawing-room. About nine thirty he would usually go to his bedroom, where he read or wrote, sometimes lying in bed, until midnight, when he would retire for the night. It was always marvelous to see him so continuously and persistently intent upon his work. When one was familiar with his capacity for endurance, his power of concentration, his unbounded enthusiasm, his deliberate, persistent, painstaking work, backed up by his unselfishness and undaunted moral courage, it was not surprising to witness his success. His motto as a boy was: "Duty before pleasure." Later in life he needed no motto; it had become a habit for him to do what he thought was right. Difficulties, obstacles, and trouble were as nothing to him when once he had made up his mind to act. He went directly at a thing, and he kept at it until it was mastered. It was this great painstaking and persistent work that made things so clear and so definite to him, and enabled him to express his ideas so lucidly. It was also this power that developed his self-reliance and his moral courage, and made his instruments and his methods of operating so near perfect that those who claim to improve or modify them are merely working backward over the same ground that Marion Sims traveled over in perfecting them. His was the inductive method, or working and perfecting method—a developing method. He cleared away complications, and gradually simplified ideas and instruments till they approximated the truth and the best.

He was no idle dreamer; he never wandered into intangible mysticism; there was neither confusion about his work, nor indefiniteness about his aims.

His mind was always aggressive, progressive, receptive, and ingenious. He was a leader—a *practical genius*.

ON

DUPUYTREN'S FINGER-CONTRACTION; ITS NERVOUS ORIGIN.

By ROBERT ABBE, M.D.,

SURGEON TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL.

THE one deformity of the hand which has of late most interested surgeons is known as Dupuytren's contraction of the fingers—a deformity which, till his day, had been regarded as irremediable, and which even to-day is so considered, with the vicious contractions from tendon defects, by the majority of physicians and surgeons to whom the scanty literature of the subject is unknown.

It was indeed an inspiration on the part of that surgeon, whose name will always be honored by the association, that enabled him to distinguish between this disease of the palmar aponeurosis and others that resembled it closely. It was the inspiration born of hard work in a man whose energy was never tired, and who seemed to see almost all there was in the new subject at the first discovery.

If we accept the popular idea of the palmar fascia as shown in many text-book illustrations, and spoken of by some authors, we shall conceive of it only as a fan-shaped, fibrous expansion, with its narrow point touching the annu-

lar ligament of the wrist where the tendon of the palmaris longus is inserted into it, while its expansion covers the breadth of the palm at the roots of the fingers, where each of the four bundles into which it has separated divides into two leaflets, attached to the sides of the proximal phalanx of each finger. This, it is true, is the grosser part of the fascia, the glistening fibrous sheet of tissue filling the space over the flexors, the palmar arches, and the muscles. But, if we dissect with care a very lean hand, we find more that concerns us in understanding the disease now considered.

Continuous with the coarse part of the fascia alluded to is a layer or network of the same white fibrous structure—more open, looser, and thinner—covering the outer and inner sides of the palm far beyond the lines of the flexor tendons, and presenting well-marked borders, especially in the fold between the base of the thumb and the index-finger, where it gives a clean, crescentic edge, while over the palmar surface of each finger the same delicate layer continues from its base far out over the tendons toward its tip.

At every point of the grosser and finer parts of this fascia some of the fibers are seen to come toward the surface and terminate in the skin, thus interweaving through the tangled subcutaneous cellular tissue a network which effectually prevents the skin from sliding. The gross white fibers are disposed lengthwise of the palm, but everywhere cross-fibers are seen, delicate but firm, at the web of the fingers, where they constitute the fibers of Gerdy (so called by the French), and in the fold between the thumb and the index-finger. These, as we shall soon see, are often the seat of this malady, though usually the long fibers are first affected.

With this understanding of the anatomy, let us consider the history of the disease. Though Sir Astley Cooper undoubtedly recognized it, it was an unknown disease to the profession until Dupuytren described it, in 1832, giving its clear-cut characteristics as distinguished from contraction of tendons, which to the ordinary observer it resembles, being classed with the "main-en-griffe," or claw-hand, resulting either from traumatism, from abscesses, or from nerve disturbances.

He had the good fortune to dissect a hand so affected, and but a dozen other dissections of marked cases have since been made. They all verify entirely what he found—namely, that there was a tightly drawn band of fibrous tissue, an enlarged fasciculus of the palmar fascia, lifted far above the flexor tendons and drawing down the fingers at one or more points in the palm; that the skin was quite adherent to the band in places; that the tendon itself lay below it, in its normal position, glistening white, and unaffected by the morbid process; and that the bones and joints were entirely free from disease.

He located the disease in the fascia only, and most surgeons agree in this view, though M. Le Fort thinks it a general inflammation of the cellular layer of the subcutaneous tissue, and not of the aponeurosis alone, because, as he says, this contraction runs down on the fingers and is sometimes found on the thumb, while the palmar-aponeurosis tendons terminate practically at the phalanges.

Thus it is evident he shares with many the erroneous

* Read before the New York Academy of Medicine, April 17, 1881.

views of the narrow limits of the fascia. Eulenberg, in 1864, insists that the thumb has no connection with the palmar fascia. Practically the entire palm is very rich in tissue which has for its base white fibrous tissue, and it is impossible to separate this from the simple cellular tissue.

In an excellent review of the subject, eight years ago, Dr. Post expressed the opinion that the sheaths of the tendons were also involved in some cases.

Goyrand's dissections proved that they were sometimes involved at the root of the fingers when the fascia draped over the tendon beyond the arch of exit. The tendon itself in these cases is still healthy, though tied down by external fibers.

Contrary to Dupuytren, Goyrand held the new bridges to be entirely new tissue. It is a matter of little importance, as the microscopical structure, according to Richer (the only observer), shows it to be simply hyperplasia of the white fibrous tissue.

The true "Dupuytren contraction" rarely appears before middle life. This observation, noted by all writers on the subject, is verified by the admirable paper by Dr. W. W. Keen, of Philadelphia, published two years since, in which he reports a collection of 105 cases from every possible source, and finds the average time of development is at forty years. It is rare in women—not oftener than one case in twelve.

From a clinical point of view, the cases present themselves about as follows: The sufferer, otherwise in good health, notices a slight hardness of the palm of one hand—either a small kernel, like a split pea, fixed beneath the skin at the center of the middle transverse crease, or else a hard cord, at the same site, in the line of the tendon of the ring-finger. It is usually painless, and perhaps for years scarcely excites curiosity until the ring-finger or little finger, as the case may be, resists being straightened out with the others.

Several nodes and bands may show themselves, or there may be only one from first to last. The band can early be felt beneath the skin before it can be seen. Then in time it forms a ridge, and finally, after progressing and shortening for from two to twenty years, it appears like a tight string to a bow, extending from near the wrist to the proximal joint of the finger, which it draws over until it approaches the palm. The skin is lifted from a quarter to half an inch from its former level, adheres to the band in parts, is puckered and wrinkled, and dimpled where fibers of attachment hold it back against the drawing tendency of the band toward the wrist.

It is with great difficulty at first that one can convince himself that this is not a tendon below the skin; indeed, Mr. Adams, who has given our best English *résumé* upon the subject, says he cut at first many times, believing he was cutting tendons. I have been asked by one of our most eminent surgeons, while my knife was just ready to cut the band, "if I was *really* sure I was not cutting the flexors."

Three convincing proofs are these: The flexor tendons are bound down at the metacarpo-phalangeal articulations by such arched fibrous sheaths as *can not* stretch to allow them

to rise from their beds, while it is exactly at this point that the fascial bands are most prominent, and certainly rise from half to three quarters of an inch above the tendons.

Secondly, the tense cords are not always in the line of the tendons, sometimes lying between instead of over them and forking at the web of the fingers by the tightening of the fibers of Gerdy, so as to take firm grip on the neighboring sides of the two fingers, while in some cases rigid cords appear on the thumb or in the web between it and the index, entirely out of the course of any tendon.

Thirdly, when the bands have been divided and the fingers stretched, the patient has the power at once to put the flexors in action and close a tight fist. Could he do this if the tendon had been cut?

The malady affects, by choice, the ring and little fingers of either hand. In Keen's collection of 105 cases, the ring-finger suffered in 88, the little in 77, the middle in 45, the index in 13, the thumb in 9.

Within from six months to a year or two, however, after the first hand is seized, the opposite one is affected in a large majority of cases; and by preference the malady fixes itself on the corresponding part.

Throughout the literature of the subject I find little reference to the associated pains, and, though I am aware that many cases are without it, there are many where it is an important symptom.

CASE I.—In the first case that came under my notice, in 1881, the successful termination of which I reported in the "Illustrated Quarterly of Medicine and Surgery," in 1882, there had been contraction of the left little finger for seven years, and of the right ring-finger for one year. The latter had given the patient increasing pain for a few months before I saw him, so that he was obliged to give up work, and, as I then reported (and repeat here, as it illustrates a point in the theory of the ætiology of the disease), "for two months this band in the right palm had been so constantly in pain that he could not move this hand up to touch his head without almost unbearable suffering, and at times, especially if the palm was struck, it was much worse." (See Fig. 1.)

FIG. 1.

As the left finger had shown prior trouble and was drawn most into the palm, I operated on it two weeks before the other by subcutaneous sections. To the patient's great surprise and my own, the right hand ceased to be painful immediately after the operation on the left, and he found on the following day that he had been able to lie at night with his right hand behind his head and sleep on it without pain, which he had been un-

able to do for many months. He could also swing this hand over his head, brush his hair with it, and do various things that for months past would have caused him great suffering; and yet this hand had not been touched. I shall refer again to this case again after speaking of others. It is sufficient to say, I subsequently operated on the right stiff finger also, and the patient remained perfectly cured and resumed his work as a cloth-cutter six months afterward.

I will ask you to follow me now in three more well-marked cases, and then speak of some others in a group.

CASE II.—G. C. H., aged fifty-eight, a cloth-cutter, showed Dupuytren's contraction of both hands, with other extraordinary symptoms.

He had been a cutter for twenty years. Fifteen years ago he first noticed contraction of the left ring-finger, and thought it had come because he helped squeeze the large shears with this hand in cutting very thick cloths.

FIG. 2.

The contraction steadily increased, but was painless at first. Very soon afterward the right ring-finger began to draw up, and about the same time he began to have pain in the back, below the loins, which has grown worse for fifteen years.

He continued to work till three years ago, when his lame back and contracted finger prevented it.

One year before I saw him he applied to Dr. Seguin for the distress in his back, the fingers being a very secondary matter. Dr. Seguin gave him medicines and applied various counter-irritants to his back, even making repeated cauterizations with the actual cautery. He then tried packing his dorsal spine with ice-bags, keeping him recumbent for a fortnight, believing there was a spinal lesion, probably a pachymeningitis. It gave no relief. Electricity, static and galvanic, was then applied by Dr. Gibney. Continued faithfully for a long time, this gave a little relief to the back pain.

The case seemed intractable, and Dr. Seguin and Dr. Gibney referred the patient to me, in view of the case I had published, to see if I thought the contracted fingers were a factor in the nervous disturbance. I had little doubt it was so.

On examination, I found his worst complaint was of the rhachialgia. He complained of great pain, as of subacute rheumatism, in the lumbar and two or three lower dorsal vertebrae, most marked on rising from a seat or on attempting to stoop. To use his own words, "he could not pick up a thousand-dollar bill if it was on the floor before him, because of the pain and stiffness." Every motion he made bore witness to the truth of his statements. He had never had rheumatism or gout, nor had his father or mother.

The ring-finger of each hand was contracted, as shown in the cut (Fig. 2); the left more so than the right. On the right the middle finger was also somewhat involved. The skin was

much puckered over the contracted fascial band from the second phalanx to the upper part of the palm. The band was very distinct and unyielding.

June 24, 1882.—I operated under ether, dividing the left band by six subcutaneous cuts, and the right by four. These rectified the attitude of the fingers perfectly, and I put them on straight splints. The subcutaneous cuts healed immediately, but the patient had considerable pain in the fibrous structures about the palm and fingers, which became thickened, tender, and somewhat stiff in their new position. It was some weeks before the subacute inflammatory stiffness subsided.

Meanwhile, what about his back? Even so soon as a day or two after the operation he spoke of an amelioration of the pain. It improved daily until, on July 4th—the tenth day—he expressed the greatest delight and surprise that his back hurt him but little, and he "could now stoop and pick up that thousand-dollar bill, or anything else." I tried him with a small object, and he could stoop freely.

For two years he had not been able to dress himself on account of the pain, and now, on the tenth day, he said, except I had his fingers on splints, he could dress himself.

I have watched him for nearly two years. In fact, he has haunted me fortnightly at my clinics and office, to express his gratitude and show his continued health.

All pain entirely left him, and has never returned. The fingers were somewhat rigid as regards complete flexion for nearly a year, but have now been perfectly restored, and he can shut them tightly down into the palm.

CASE III.—L. H., aged fifty-seven, a Boston gentleman, was kindly referred to me by Dr. Fordyce Barker for double Dupuytren contraction. His mother had some contraction of the fingers, coming on after the age of fifty years, for which, he remembers, she used to sleep with a rubber ball in her hand to prevent further contraction. She also had some trouble in one knee, which became stiff in a flexed position. She had never had gout in her feet.

The patient's father never had gout or rheumatism. Nine years ago there began a contraction of his palms, first in the right hand, involving the ring and middle fingers, very soon after of the left also. It was usually without pain. The left ring-finger gradually drew down, until three years ago its tip touched the palm. Two years ago Dr. Twitchell, of Keene, N. H., made one subcutaneous cut of the band in the palm and released it partially, so that it stood as now shown (Fig. 3), and it had since kept all that was first gained.

FIG. 3.

The right hand had slowly progressed until every finger was involved as follows:

One sharp crescentic band stretched tightly in the web between the thumb and the index-finger from base to base, with

a spur running up on the first joint of the thumb. This held the thumb rigidly in toward the palm. Another band, inserted into the skin near the second joint of the index, followed up the palm in the line of the flexor tendon, to the thenar eminence, with a spur into the center of the palm. A solid band extended from the base of the second phalanx of the middle and ring fingers straight up the center of the palm nearly to the annular ligament, and one ran from the palm to the little finger.

On the left hand one rigid band stretched to the ring-finger, and one between the bases of the thumb and the index.

The deformity was very great, and, besides, there had been several times yearly an attack of painful subacute swelling of these fingers, especially at the joints, keeping him awake nights, and relieved by no anti-rheumatic remedy except the French preparation of Dr. Laville.

The patient had therefore come to brood over the discomfort and unsightly appearance, and was giving up his favorite pastimes of driving, whist, and Shakespearean recitations. He could not sweep in a trick of cards, grasp a goblet of water, put on a glove, etc., and insensibly it had produced a decided impression on his spirits.

On February 26, 1883, I operated under ether on his worst hand only. The bands were all cut at points of tension, beginning nearest the wrist, and repeated until the fingers were released. Adhesions to the skin and deeper parts prevented any one cut from doing all the good, so that when all the bands were released I found I had made twenty-five subcutaneous cuts. (See Fig. 4.) The hand was dressed antiseptically and invested with plaster of Paris, all the fingers being extended. The patient began to come out of the anæsthesia before I had dressed the hand, and involuntarily closed his fist with the greatest tightness, showing the flexors to have been untouched by the cutting.

The local pain from the unwonted extension was severe for two days, but lessened gradually until the tenth day, when an increase suddenly took place resembling subacute rheumatism of the various knuckles. He took colchicum and iodide of potassium, and his favorite "Laville," but without benefit. One or two fingers had to be released from all restraint before it was endurable, the patient having tossed in bed several nights in spite of morphine in moderate quantities.

The cuts all healed at once, but a firm, resisting state of the whole fascia investing the hand ensued, with oedema, joint swelling, and pain, but no cellulitis or dermatitis. Sedative lotions and anointing gave him ease. Brief immersion in hot water made them temporarily more supple, and was repeated several times daily. The splints were lightly bound on at intervals.

It was two weeks before the hands began to quiet down. The fingers retained a somewhat stiff, fibrous investment, which prevented flexion at first, but by degrees this has disappeared and excellent flexion has resulted.

It is now a year and two months since, and the patient has kept every particle of extension gained by the sections,

with an almost complete return of the power of flexion. He is able to make a fist, bringing the tips of all but the little finger into the palm by voluntary effort.

The joint of the little finger had been so surrounded by old dense fibers that I preferred not to cut deep among the tendons, so it was but half released. But now the slight flexion looks more natural than a straight little finger.

Quite as important as the local change is the fact volunteered by the patient's wife, and corroborated by him, that he has not been so well in general for many years as since the hand was released.

There has been a gain in flesh, his nerves are quiet, his mind is serene, he sleeps well at night, and never has pain in the hands.

CASE IV.—F. S., a gentleman of sixty years, whom Dr. James Knight very kindly referred to me with contracted little and ring fingers of each hand. Fifteen years ago he sustained

FIG. 4.—THE RIGHT HAND OF THE PATIENT WHOSE HANDS ARE SHOWN IN FIG. 3. The dotted lines indicate the contracted fascial bands, and the heavy cross-lines the twenty-five subcutaneous sections.

FIG. 5.

a slight cutaneous laceration at the middle flexion-crease of the right little finger while helping to carry a trunk. Within two months a slight buncy swelling just above it and a little drawing of the finger were noticed. Dr. Sayre, the patient said, had tried to straighten it by a posterior splint and rubber band, without benefit. Within the next year the little finger of the opposite hand took on the same action at the same point, and the ring-finger of the right hand also, but not until five years later did the ring-finger of the left hand take on its contraction. (See Fig. 5.)

In 1871, 1874, and 1876 the bands were divided subcutaneously at one or two points each by Dr. Hammond and Dr. Stephen Smith, but no splints were used and recontraction took place.

There has never been pain in the parts. The patient neither inherits nor has acquired rheumatism, gout, or other taint. Each hand presents a dense subcutaneous band in the palm, running from near the wrist to the neighboring sides of the ring and little fingers, very symmetrical, though the left one draws down most. No amount of pulling can extend them farther.

February 1, 1884.—I divided the bands by Adams's subcutaneous method in each hand, the patient being etherized. On cutting the bands one can appreciate that, although so much like a tendon in appearance, it is a tense, ribbon-like band, that the point of the knife quickly cuts through. I always prefer passing the knife between the skin and the fascia and cutting downward.

At the web of the fingers the cross-fiber bound the fingers rigidly together, but yielded beautifully to subcutaneous cuts, letting the fingers gape widely apart. After the bands disap-

peared two of the joints were found to have a moderate extra-capsular fibrous thickening, and had to be forcibly extended. Twenty cuts were necessary in each palm. The hand was dressed antiseptically, and rigidly extended on posterior splints.

He suffered acute pain for many hours after on account of the severe stretching, but was easy directly I released the fingers. I continued pretty full extension, however, for a week, during which time there ensued the same condition I had seen in each of the other cases—to wit, a general hyperæmia of the deeper tissues, especially about all the knuckles of the hand; a firmness of the aponeurotic layers, and puffiness and tenderness of the joints, all going to make up a close resemblance to sub-acute rheumatism.

I believe this to be solely due to nerve irritation, and not, as supposed by other observers, to be an attack of rheumatism.

After two weeks the patient used his splints only at night, and two weeks later only at intervals of two days.

It is now eleven weeks since the operation, and this much has been accomplished: The two ring-fingers can be extended by voluntary effort perfectly straight, and one can be already flexed so as to nearly touch the tip to the palm. The other only flexes to a right angle with the palm. The little fingers flex and extend imperfectly, but all are gaining, and, when the dorsal fascia softens enough to give the flexors a chance to bring the fingers over, they will do their part.

The trouble following operation is not in the flexors, but in the fibrous tissues generally.

(To be concluded.)

THE TREATMENT OF DIPHTHERIA AND CROUP

BY LARGE DOSES OF BICHLORIDE OF MERCURY.

By WILLIAM M. THALLON, M. D.,

BROOKLYN, N. Y.

(Concluded from page 405.)

These ten cases constitute all the clinical material I have to present to the society this evening bearing on this question. I had one other interesting case of diphtheria in which I used the bichloride treatment, but it was some two years ago, and, as I did not keep notes, I hardly can quote it correctly from memory. The child recovered. And I may say that I have not lost any case from croup or diphtheria since adopting this method of treatment, and the same, I believe, is the experience of Dr. Skene. I have had several cases of sore throat marked by the abruptly limited line of inflammation which is so characteristic of diphtheroid conditions, as distinguished from the wide-spread area of redness in general pharyngitis and tonsillitis, but, as they never showed any true membrane, I will not recount them. Whether the fact of their never having done so was due to their being promptly brought under the influence of bichloride of mercury I shall leave for the society to determine.

I may say just here that, when called in to attend a case of diphtheria or croup, I make it an invariable rule to make the relatives or attendants take a tonic mixture of bichloride of mercury and tinct. ferri chlor. for a few days as a prophylactic measure. It seems to me that we can thereby guard them, to a certain extent, from the risk of infection.

On reviewing these cases it must be admitted that, with the exception of the first, the second, and the ninth, they are

tolerably mild in type. We have not had any severe epidemic of diphtheria among us, fortunately, within the last three years, and I at once frankly acknowledge that the value of the bichloride-of-mercury treatment will not be established until it has proved efficient to cope with such an epidemic. It is very difficult in a discussion like the present, indeed I may say impossible, to draw a positive therapeutic conclusion from treatment used in sporadic cases only. Still, enough has been shown, I think, to warrant the claim that this mode of treatment is well worthy of a more extended trial. And the hopelessness and confusion of all other methods of treatment are such as to make us eagerly resort to one which is so plausible as this, and one that already has so much clinical evidence in its favor.

That is all I claim for it, and my principal object in bringing the matter before the society was to invite a more extended trial of the method in question.

If we turn for a few moments to a consideration of the rationale of the method in question, we enter a very interesting and very unsettled domain. In the application of any remedy to a given disease we are always much influenced, either consciously or unconsciously, by our conception of its pathology.

Now, in the first place, I am a strong believer in the essential identity of the pathological processes which are called in our text-books diphtheritic and croupous. I believe that the differences which exist between them are not essential, but are incidental to the different conditions as to age, anatomical locality, habit, etc., under which they manifest themselves. I shall therefore simply allude in my further brief remarks to the diphtheritic process.

I believe it is generally acknowledged by authorities that there are two modes under which the diphtheritic process manifests itself, namely, the inflammatory and the septic. These two undoubtedly shade into each other at all stages, and in some cases it is impossible to state which element is the more pronounced, but the division is a useful clinical one.

Under the inflammatory type may be classed more especially the ordinary membranous croup of children, the cases of pharyngitis and tonsillitis with diphtheritic exudate, and some of the sporadic cases of diphtheria. Under the septic type come those cases which we meet when a virulent epidemic is prevailing, and such sporadic cases as our first one, narrated above, where a well-marked source of septic infection can be clearly traced. And it is to the second class, the septic type, that the cases of sloughing sore throat of scarlet fever are most nearly allied.

In the inflammatory type there are certain pathological indications which mercury seems peculiarly to meet. I think it will be disputed by no one that, whatever else is undecided about the general inflammatory processes, it is a fact that in these states there is a marked increase in fibrin or its constituent elements in the blood. And, because of this excess of plastic material in the blood or accompanying it, we invariably find that wherever the inflammation becomes localized—whether on a serous membrane, as in pleurisy or meningitis, or on a mucous membrane, as enteritis, or pharyngitis, or cystitis—there is at a particular stage an exuda-

tion of plastic material. Now, if there is a settled fact in therapeutics, it is that the free and prompt administration of mercury lessens such plastic exudate.

It is now nearly a hundred years since Dr. Robert Hamilton brought before the notice of the profession the value of mercury as an aplastic antiphlogistic, and since then the weight of clinical evidence in support of this claim is overwhelming. The oft-quoted and plainly visible example of the exudate in iritis lessening under mercurialization is entirely to the point. Even though it be admitted that iritis is generally, though not always, syphilitic in its origin, I can not see how that detracts in the least from the value of mercury to lessen general inflammatory exudation because it has proved competent to lessen a specific inflammatory exudation. I think, then, we are warranted in saying, in reference to the diseases in question, that bichloride of mercury lessens the formation of exudate.

It has another action closely connected with the foregoing; up to a certain point it promotes excretion. That action is not confined to one gland, but is common, so far as I know, to the salivary glands, the mucous glands, the kidneys, the intestinal glands, the pancreas, and the liver. The measure to which glandular excretion is being excited is a very important one, and the process has to be very closely watched. It is probable that the action of the bichloride of mercury is destructive to certain elements in the circulatory fluid, and forms with them a chemical compound which in its turn, being irritant to the glands, calls for elimination. If these large doses were given in health, it is likely that they would prove highly injurious by attacking normal tissue elements essential to the continued welfare of the economy. Such is the case in the examples of acute and chronic mercurial poisoning we meet with. But in acute general inflammatory disease, if the foregoing is true, we have a far less highly organized product than the simplest tissues, and the mercury attacks this first. This exactly corresponds with what we know of the use of mercury for chronic conditions, notably syphilis.

I can easily see that the drug, if heroically pushed after the subsidence of the acute stage, would be capable of doing great harm. We have a convenient clinical indication of the extent of its action, its destructive action especially, in the effect produced on the salivary glands. It is well known that it is difficult to salivate with the bichloride of mercury compared with the other mercurials, especially calomel. This entirely corresponds with my experience in giving these heroic doses, for, although I was carefully on the watch in the foregoing cases for the least sign of salivation, in not one did any sign of it appear, and this I think is very remarkable.

With reference to its action on other glands, I am quite convinced that it increased the secretion of the mucous glands, especially of the respiratory tract, causing freer expectoration and loosening the exudate by maceration. I was somewhat surprised, however, by the apparently slight action these doses had on the liver. I confidently expected to have to exhibit opium in combination with the bichloride to lessen the tendency to diarrhœa and abdominal pains; but such was not the case; on the contrary, in several cases I

had to order an enema or a laxative to produce sufficiently free movements from the bowels.

I do not wish to dogmatize, but I am inclined to think that the bichloride of mercury in amounts varying from one tenth to one grain in the course of the day is *the* treatment in the inflammatory type of the diphtheritic diseases, especially in the beginning. Of course, I do not for a moment lose sight of the paramount importance in all cases of good hygiene and food; and, further, other drugs, as alcohol, opium, quinine, etc., can be combined with the bichloride if the indications for their special use arise. But, to constitute a fair trial of the method in this type of diphtheritic diseases, the bichloride must be given in at least that minimum dose, and in the way and with the precautions I have insisted on.

If we turn now to the more markedly septic type of the disease—the malignant cases of diphtheria—what I have to say is offered merely as a suggestion. The clinical evidence I have presented to you has been almost exclusively confined to the first type of the disease—the inflammatory type—so that my further remarks are mainly speculative and theoretical. The septic cases of diphtheria are those which prevail in epidemics, and we have a great additional factor to consider. The patients die from the effects of a septic poison, and the bodies undergo unusually rapid decomposition. All of these facts point to a process closely allied to putrefaction and accompanied by, if not due to, the presence of certain morbid organisms. So much will be granted by nearly all competent observers to-day, even although we are not prepared to pin our faith to a particular bacterium or specific micrococcus.

Now, the question arises whether you can hope to prevent, or arrest, or retard such a process by a germicide. At present our knowledge is far too slight to say positively whether this is possible or impossible, but I think the following facts are highly suggestive. It has been proved by reliable experimenters, both abroad and at home—notably by Robert Koch in Germany, and Sternberg in the United States—that if you take a liquid like beef-juice, swarming with bacteria, and add $\frac{1}{30000}$ part of bichloride of mercury, these organisms speedily cease their activity; while if you add half as much again ($\frac{1}{60000}$ part), they not only cease their present but their future activity. The fluid thus sterilized will fail to excite putrefaction in any other organic solution.

Now, taking this fact as a basis, the calculations I made were to determine how much bichloride would be necessary, if added to the blood, to sterilize it. The amount of blood is given by Dalton as about 12.5 per cent. of the total bodily weight, while Foster gives it as about 8 per cent. I think Foster is more nearly correct, but let us assume it as 10 per cent. But I would remind you that this is the proportion in health, and is subject to large daily variations, which may become permanent variations in disease. In an adult of 150 lbs. the blood weight we assume at 15 lbs., and, taking the $\frac{1}{30000}$ part of that, it would give us about 5 grains of the bichloride to sterilize the blood, or the $\frac{1}{30000}$ part (= $3\frac{1}{2}$ grains) to arrest decomposition. In other words, each pound of blood would require $\frac{1}{6}$ grain of bichloride to sterilize it, or $\frac{1}{2}$ grain to keep it sweet, provided

the diphtheritic decomposition and the ordinary decomposition are arrested by the same percentage of the antiseptic.

But there is a very important consideration which must not be lost sight of, and it is this: that the experiments of Koch and Sternberg relate to decomposition of organic fluids *outside* of the body. Now, it is well known that living tissues offer a certain amount of resistance to the invasion of these organisms. The onset of the hosts of invasion may be so severe that they overpower such resistance, and then the cells die and form the pabulum to nourish new hosts of invaders, and, if this process goes on far enough, the individual dies. But until the cell is dead it continues to offer some resistance. Now, in the tissue which we are considering—the blood—there are two elements—the corpuscles and the fluid medium in which they circulate. Both of these resist to a very considerable degree the process of decomposition due to putrid organisms—the corpuscles in common with all other living cells in the body—the serum because of its antiseptic properties. I have not time to more than allude to the extended researches of Sir Joseph Lister, in which he conclusively shows that the serum, so far from being prone to decomposition, will resist it to a degree greater than some of our weaker antiseptics. And the same is true of the other fluid constituents of the body (relatively so much greater in amount than the blood), their contained salts tend to keep them antiseptic.

The element in the blood of these inflammatory conditions which is so liable to decomposition is the fibrinoplastic material so largely in excess, and we have seen the action of the bichloride in lessening its formation and eliminating it when formed. I therefore believe that the amount of antiseptic that will have to be added to render the blood aseptic in the living body will be far less than is needed for the same fluid—outside of the body—offering no resistance to the process of decomposition. It is impossible at present to make any estimate, even approximately, as to how much these two factors respectively contribute to this end; but that they *do* so contribute is, I think, certain.

Taking up one of my individual cases (No. II), how much bichloride of mercury was at any one time in her system? We know the quantity given. The question, then, arises as to how rapidly it was absorbed, and in what form and how rapidly eliminated. On these points we are much in the dark. It seems proved that elimination is much slower than absorption, and that the drug, therefore, has a cumulative action.

Thus, in experiments on dogs, Mayençon found the drug continued to be excreted four or five days after it ceased to be given. And, in some experiments on himself, the above-named author found that elimination was not continued till all the drug was discharged. For, "forty-eight hours after the cessation of a mercurial course, when the urine was free from the metal, the iodide of potassium was exhibited, and the urine of the next twenty-four hours contained an abundance of mercury, which continued to be present in diminishing quantities for seventy-two hours." This is entirely in accord with clinical experience, where deposits of metallic mercury have been known to take place from such accumulation. Now, in Case II the weight was about 40 lbs.; that

would make the weight of blood about 3 lbs. according to Foster, or 5 lbs. according to Dalton, or, according to our assumption of 10 per cent., about 4 lbs. In order to sterilize that weight of blood would require: bichloride of mercury $\frac{1}{3}$ gr. for each pound, = $1\frac{1}{3}$ gr. in all. To totally arrest any septic process would require: bichloride of mercury $\frac{2}{3}$ gr. for each pound, = $\frac{2}{3}$ gr. in all.

Now, in the course of five days and a half she took over two grains, and in the course of twenty-four hours half a grain. Now I would like to ask if it is so entirely out of the way to suppose that, at one time during this period, there was not enough bichloride of mercury circulating in the blood—either in a free state or in a state of organic combination—to arrest, or at least modify, the septic process?

I am sorry I have nothing more exact than these guesses to offer the society on these points. But, as I said before, I shall base the claim I make for the bichloride of mercury treatment in diphtheria and croup on the clinical evidence, especially in the first or inflammatory type of the disease. And I can only ask from the society in the discussion the fullest expression of opinion, both for and against the method of treatment. But I venture to suggest that the use of bichloride of mercury in large doses in the treatment of diphtheria and croup will give better results than any other method of treatment known at present.

THE TREATMENT OF GONORRHOEA.*

By S. C. GORDON, M.D., PORTLAND, ME.,

SURGEON TO THE MAINE GENERAL HOSPITAL; LECTURER ON DISEASES OF WOMEN IN THE PORTLAND SCHOOL FOR MEDICAL INSTRUCTION.

It may be fair to assume that a majority of cases of gonorrhœa that come under our observation are more or less protracted beyond the time ordinarily described as the natural course of the disease. It is certainly true that it is very much more protracted than a majority of patients are content to wait, and therefore we find many of them following the advice of almost any druggist or friend who has some "sure cure." What is most wanted is a remedy that aborts the disease, or relieves the discharge and inflammatory results in less time than is usually done when the disease has passed beyond the primary stage.

From a very large experience during my army life, I became convinced that the routine treatment of mild injections and the balsams and other nauseating mixtures had very little influence toward shortening a disease that, if left to itself, under favorable circumstances, would last but three or four weeks.

I have been reminded recently, by an old sergeant of one of the companies of my regiment, that in the city of New Orleans, where the regiment was stationed for a few weeks, one morning he presented at surgeon's call upward of twenty-five men of his own company who were more or less ill from "ladies' fever," for that was the name by which it was familiarly known.

I tried the abortive treatment with a very strong solution of nitrate of silver, and also with the weak solution, very frequently repeated, until bloody discharges were pro-

* Read before the Portland Clinical Society, January 3, 1884.

duced, with occasional good results, but more often with a failure; and the last state of the man was far worse than the first. The balsams disturbed the digestion and destroyed the appetite, so that the remedy was worse than the disease, and I preferred that the soldier should eat and keep his strength, even if the gonorrhœa seemed to be neglected, although, in fact, improvement was about as fast in the one case as in the other.

That experience about convinced me that any such plan as was ordinarily recommended in the literature of the day did little more than nature did; so for several years, until three years ago, I ordinarily put the patient upon a simple cleanly plan, which embraced the use of warm-water injections sometimes medicated with some opiate, bathing the penis in very hot water for a long time at short intervals, diluting the urine by drinking plenty of water, and using a good nutritious diet, cutting off stimulants as a rule. By this plan I could in a majority of cases promise a cure in three or four weeks, rarely in less time.

Three years ago this very month a gentleman came to me having had gonorrhœa about two weeks. His domestic relations were such that he was extremely anxious for a speedy recovery. The inflammatory process had ended, but the mucous membrane was swollen and engorged from the exudate and from passive congestion, while the urethra felt like a whip-cord from the submucous deposit that had taken place. The disease had extended the entire length of the canal, and the bladder was suffering in consequence, so that dysuria was a constant symptom.

Previous to that time I should have been content with prescribing an anodyne and diuretic and have used as many placebos as my ingenuity could devise. Certainly several weeks must elapse before such a case can be cured under such a plan of treatment as that. My daily experience with the hot-water douche in similar conditions of the genital organs in the female suggested that, if I could pass a current of hot water over this diseased urethra, as I would inject gallons of hot water into the vagina for cervical endometritis, vaginitis, and pelvic exudate following peritonitis and cellulitis, surely I could accomplish much more than by the ordinary small syringe. The suggestion was father to the act, and, telling my patient what I proposed, and he assenting to anything that promised speedy relief, I filled a fountain-syringe with a quart of water at a temperature of about 100° F., and, with one of the small tubes introduced into the urethra as high as I could push it, I injected it and allowed it to run back into a vessel. It ran back by the side of the tube, washing the urethra as far as it was thrown up. The first trial acting as a sedative, or at all events giving no pain, I filled the fountain again, this time increasing the temperature about 10°. I found that, by asking the patient to strain a little as if urinating, the urethra could be sufficiently dilated to allow the water to pass into the bladder, and in that way I filled and refilled the bladder several times, allowing him to pass it off himself each time. The relief afforded by this second injection was immense, and from that moment the dysuria ceased to be an element of much trouble.

This douching I continued twice each day, and in three

days I had the pleasure of seeing my patient practically relieved of *all the unpleasant symptoms*. A very slight discharge remained, but a repetition of the same treatment for a few days more completed the cure. From the first day of the injections no anodyne was needed, and no medicine was given. The chordee was relieved, the burning sensation removed, and the patient happy.

Within the year following I had an opportunity to make other trials of the treatment, and in each case I was more than satisfied. To any one familiar with the rapid melting away of pelvic exudate, under the use of the large douches of hot water, it will not seem strange that the effect upon this mucous membrane should be almost magical. The cure was so absolutely complete that the ordinary dragging along, consequent upon more or less stricture, was entirely absent.

Finding such good results in cases where the primary stage had past, I determined at the first opportunity to try the effect in a case at the commencement, if I could see it early enough.

The case was not long in coming, being of only twenty-four hours' duration when I first saw it. I administered two quarts at the first sitting, waiting a few minutes between the injections. This time I used water as hot as the patient could *possibly bear it*, at times being obliged to stop on account of the severe heat. If it did not actually scald the parts, I felt that it would be more sure to abort the disease, this being the object I had in view. I continued this twice each day, and at the end of the third day the patient told me that all discharge had ceased. A sudden demand in a business way took him from my care, and I did not see him for two weeks, when he came back saying that two or three days after leaving me, having no means of using the injections, he had a slight discharge, which continued three or four days and then disappeared.

The next case came under my care at the end of the third day from the beginning. I had but little hope of doing much in the way of aborting it, and the result proved my fears to be well founded. I tried the hot water faithfully for three days, and while, unlike the strong solutions of nitrate of silver, it did no harm, I am sure it did not change the course of the disease: so I suspended the treatment, using only a mild course until the inflammatory process was ended, then returning to the douche with good, yet not such rapid, results.

The next two cases were in quite young men, one of whom I had treated for a previous attack by the old expectant plan. I am sure that by that plan he was several weeks in getting well, although it was a very mild case. Within the past year he came to me with a well-developed gonorrhœa in the early stage. I saw him first on Friday (as I find by reference to my note-book), again on Saturday, giving the injection twice each day, and on Monday morning he came in saying: "I am well, and have been since Saturday night."

The other patient was an old offender (although young in years), having had three previous attacks, one of which lasted a year. He had been under all sorts of treatment, however, before consulting any regular physician. His for-

mer experience had taught him by this time to seek competent advice early, and I saw him within twenty-four hours. I administered the first injection myself, and, as he had a friend with him who was a druggist and room-mate, I prescribed a fountain-syringe and sent him away with orders to carry on the treatment with the aid of his friend, which he did successfully within a week. I only fear that his elation at the prospect of getting out of it so easily may tempt him to break some of his good resolutions made in former hours of sorrow.

In conclusion, I can give only a brief summary of the cases in which I should expect the most satisfactory results from this mode of treatment:

1. I should hope, and confidently expect, to abort, in from three to five days, a large majority of cases that were treated as soon as the first well-known symptoms appeared. In these cases I use the injection as *hot as it can possibly be borne*—three or four times in twenty-four hours; at least two quarts should be used at each time.

2. In cases of ten days' or two weeks' duration (at which time the inflammatory process has ended), I believe the most of the trouble can be relieved in a very few days. The suffering so characteristic of that stage will usually pass away in twenty-four hours. In many of these cases I have been enabled to force the water into the bladder and then allow the patient to pass it away immediately. This has a good effect upon the dysuria, relieving it almost at once. In this class of cases, also, the water should be very hot.

3. Where two or three days have elapsed before the patient is seen, I do not expect so much as in the former classes. Even here much may be done by the external use of very hot water and the careful, gentle use of the fountain-syringe, filled with *simple warm water*, at about the temperature of the body, or less. This promotes cleanliness, and is a sedative.

I would add that my three years' experience fully justifies me in commending this plan to the attention of the profession.

NEW YORK, SATURDAY, APRIL 19, 1884.

THE MEDICAL SERVICE ON BOARD PASSENGER SHIPS.

On several occasions we have referred to various defects in the provision made by ship-owners for the medical care of their passengers, as well as to their failure in too many instances to treat their medical officers in such a manner as to encourage competent men to enter their service. In Great Britain, thanks in great measure to the efforts of Dr. Irwin, the shortcomings of the Transatlantic steamship lines in these matters have secured some attention, and it is to be hoped now that, so far as this country is concerned, Congress will see the importance of passing some such bill as the one now before it, the full text of which we print in this issue of the journal.

We understand that the bill was framed by a committee appointed for the purpose at the last meeting of the American Public Health Association, consisting of Dr. A. N. Bell, of New York, chairman, Dr. J. N. Quimby, of New Jersey, Dr. Henry O. Marcy, of Massachusetts, Dr. Henry H. Smith, of Pennsylvania, and Dr. Albert L. Gihon, of the navy. The bill may be thought to be defective in not precisely defining the minimum size of the hospitals, but some discretionary power may well be vested in the medical officers in regard to this point, especially in the light of certain considerations brought forward by Dr. Gihon in his paper entitled "Thirty Years of Sanitary Progress in the Navy," to which we lately alluded. According to Dr. Gihon, permanent bulkheaded hospitals or sick-bays should be done away with on board men-of-war, for the reason that they are always too small when there are many on the sick-list, while they are too large for efficient and economical operation when the list includes but few. It is in the hope that medical officers endowed with discretionary power may see fit to adopt his views with regard to "flying hospitals" that we regard the omission of a precise definition of the space to be allotted to the hospital on board ship as not wholly a defect of the bill.

The objections that Dr. Gihon has urged against permanent hospitals on board men-of-war apply with scarcely less force in the case of merchant vessels carrying passengers between Europe and this country, in view of the usual disparity between the number of passengers on the eastward and on the westward trip. The "flying hospital" is designed to separate a space, of such size as may be required under particular circumstances, by means of canvas panels, as is explained in the paper we have referred to.

THE HOSPITAL SATURDAY AND SUNDAY COLLECTION.

In view of the apparent gusto with which certain correspondents of out-of-town publications have predicted that the collection for the year 1883 would show such a falling off from

those of former years as to evince a growing apathy on the part of New Yorkers in regard to the support of the private hospitals of the city, it is particularly gratifying to be able to record the actual facts as they are set forth in the annual report of the association, just made public. It appears from this document that the sum collected for the year 1883 amounted to \$43,062.74, or more than \$12,000 in excess of the collection for the preceding year, and only a little over \$1,000 less than the largest collection ever made, that of the year 1880, which latter sum included a special gift of \$5,000. A like special gift was received in the only other collection that approaches that made in 1883. In the light of these facts and of the commercial depression that marked the close of the year, the time when the collection was made, the association seems abundantly justified in interpreting the result of its labors for the year as decidedly encouraging.

But it is not alone in the matter of the gross sum collected that an inference is to be drawn implying that the people of New York are not flagging in their interest. Looking over the list of sources from which the contributions were derived, we notice a great many that have never figured before, including a large number of churches and various financial and other organizations, as well as several of the different branches of trade. On the other hand, it is quite rare to find in the lists a blank opposite the name of any former contributing organization. The association may derive satisfaction also from the small proportion of "designated" contributions, being those accompanied by a specification on the part of the contributor of the hospital to which he prefers his gift to go. This indicates a degree of confidence in the association's plan of dividing the money that could not be felt except for good reasons.

THE WAR OF THE LOUISVILLE COLLEGES.

THE Louisville Medical College, for that is the institution against which Dr. Yandell's criticisms, recently alluded to in this journal, were directed, seems as far as possible from resting content to let those criticisms pass unnoticed. In a supplement to the "Medical Herald," Dr. E. Miller, the secretary of the faculty, denies that the Louisville Medical College issues beneficiary certificates, or that it attempts to allure young men to take its course. Dr. Miller adds, however: "For the last session we did write to a number of students, whose names had been furnished us by their friends, offering to take them at reduced rates, as we had a perfect right to do, as is done by every college in the land, and for the following good and sufficient reasons"—and then goes on to give excuses for the college's having on a particular occasion done what he has denied that it is its practice to do, the main point brought out being that the university was at the same time endeavoring to get the students of the college away by offering to take them for only the matriculation and graduation fees, and "did take some of them for nothing."

Concerning the right of a college to set its own estimate on the value of its instruction we have nothing to say, and concerning the provocation under which the college may have acted

when it sent out the letters alluded to by the writer in question we have only to say that one can not whiten his own face by blackening his neighbor's; but we do not believe that the writer has the slightest warrant for the assertion that "every college in the land" resorts to such practices. So far as the profession is interested at all in this matter, it is to know whether or not the Louisville Medical College has done what Dr. Yandell charges it with having done, and the college can not better its position in the slightest by invective or by attempting to bring extraneous issues into the foreground. Appended to the supplement we allude to there is a list of the resident medical officers of the City Hospital for the past fifteen years, giving the standing of each man, as determined by a competitive examination before a board appointed by the Charity Commissioners, together with the name of the institution from which he received his degree. This list shows very much to the credit of the Louisville Medical College, and, if we take it by itself, we can not wonder that the college should feel pride in its publication. We do not understand, however, that the controversy turns upon the quality of the instruction given in the two institutions. The point seems to us to be this: That, if either of them has pursued the policy of ransacking the country for students in the way depicted by Dr. Yandell, it has acted dishonorably and disgustingly, and that the consequences of such a policy, if it is persisted in, can not fail to lower the tone of the profession in the region in which the college adhering to it has any influence.

MINOR PARAGRAPHS.

THE HEALTH OF NEW YORK.

THE most notable feature of the report of infectious diseases for the week ending April 15th is the increase in the number of cases of typhus, nineteen, against four for the preceding week. There is reason to believe that this increase was not owing to a spread of the disease as it already existed in New York so much as to a fresh importation, since most of the new cases have been encountered in the region east of the Bowery, and the patients are for the most part immigrants lately arrived from Hamburg or Glasgow. In each of the weeks covered by the comparative statement given elsewhere in this issue of the journal there was but one death from the disease. There was also a decided increase in the number of cases of measles, nearly double that for the previous week. On the other hand, there was a satisfactory diminution of diphtheria, and the solitary case of small-pox reported the week before has not yet given rise to any spread of that disease.

NEWS ITEMS, ETC.

THE HEALTH OF PROVIDENCE.—During the month of March, as we learn from the report of the City Registrar, Dr. Edwin M. Snow, the deaths in the city of Providence, R. I., amounted to one hundred and fifty-nine, being twelve fewer than in February, and thirty-four fewer than in the month of March, 1883. The percentage of deaths from zymotic diseases was 16.58.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—A correspondent who signs himself "A Graduate" tells us that the honor-men at the recent commencement should have been mentioned in the following order: R. H. Sayre, G. de N. Hough, R. J. Carlisle, N. S. Jarvis, L. R. Morris, A. C. Bridges, H. H. Young, S. Stark.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 15, 1884:

DISEASES.	Week ending April 8.		Week ending April 15.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	4	1	19	1
Typhoid Fever	6	0	6	1
Scarlet Fever	89	13	78	17
Cerebro-spinal meningitis	6	6	6	6
Measles	63	13	107	15
Diphtheria	47	18	39	22
Small-pox	1	0	0	0

YELLOW FEVER is reported to be prevalent again in Vera Cruz, Mexico.

THE BAYVIEW ASYLUM IN BALTIMORE.—A reorganization of the medical service of this institution has been undertaken, by which its resources for clinical instruction will be more fully made use of by the faculties of the University of Maryland and the Baltimore College of Physicians and Surgeons, each of which, we understand, is to appoint a resident medical officer.

THE STATUS OF THE MIDWIFE, LEGAL AND PROFESSIONAL, was made the subject of discussion at the last meeting of the Society of Medical Jurisprudence and State Medicine, Dr. J. H. Fruitnight having read a paper with that title. A resolution was passed opposing the establishment of a college of midwifery.

THE NEW YORK CANCER HOSPITAL.—The State Senate has passed a bill incorporating this institution.

THE BOARD OF HEALTH has appointed six temporary assistant sanitary inspectors, to do the work of vaccination for one month, on account of the necessity of employing the regular assistants in the detection of cases of typhus.

"COFFEE-ESSENCE," an article used for making coffee in some of the cheap coffee-houses of the city, has been analyzed by order of Dr. Cyrus Edson, of the Sanitary Bureau, and it is said that many specimens have been found to have been grossly adulterated, with dried blood, for example, and that the manufacturers will be prosecuted.

SCARLET FEVER SPREAD BY MEANS OF ICE.—A newspaper report from Camden, N. J., states that scarlet fever has been spread in Gloucester City by children having eaten ice which had been used by an undertaker on the body of a person dead of the disease.

RECENT PARIS THESES.—Among the recent "Thèses de Paris," as we learn from our French exchanges, are the following: On Hydatid Cysts of the Muscles, by M. Bourel-Roncière; On the Treatment of Genu Valgum by Osteoclasis, by M. Delarue; On Sudden Death from Cerebral Edema in Old People suffering with Interstitial Nephritis, by M. Deschand; On the Chief Causes of Death in Chronic Interstitial Nephritis, by M. Gaudetroy; On the Health of Workers in the Cotton Industry, by M. Kneri; On Tenonitis, or Inflammation of the Retro-ocular Cellular Pouch, of Rheumatic Origin, by M. Puechagut.

A SANITARIUM IN THE ADIRONDACK REGION is in a fair way to be opened before long, a site having been chosen near the village of Saranac, in Franklin County. It is announced that the fund raised thus far, largely through the efforts of Dr. E. L. Trudeau, amounts to \$5,300. Under Dr. Trudeau's management the proposed institution is sure to be well carried on, and we trust that further contributions may soon be made to the fund. They may be sent to Dr. Trudeau, at Saranac Lake, or to Dr. A. L. Loomis, of New York.

EXAMINATIONS FOR COLOR-BLINDNESS have been ordered to be made of the men employed on the trains of the Ontario and Western Railroad.

THE MEDICAL SOCIETY OF THE COUNTY OF RICHMOND is reported to have taken the extraordinary step of passing a resolution prohibiting any member from rendering professional services to any person against whom another member has a bill for like services which he is unable to collect.

THE FOOT-AND-MOUTH DISEASE.—The Lower House of Congress has passed a resolution directing the Committee on Agriculture to investigate the origin of the outbreak reported to have shown itself in Maine.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 6, 1884, to April 12, 1884:*

BAILY, ELISHA I., Colonel and Surgeon. Ordered to report to the commanding general, Division of the Pacific, for duty as medical director of that division and of the Department of California. Par. 4, S. O. 78, A. G. O., April 4, 1884.

SUTHERLAND, CHARLES, Colonel and Surgeon. To be relieved from duty in Division of the Pacific, and to report to the commanding general, Division of the Atlantic, for duty as medical director of that division and of the Department of the East. Par. 4, S. O. 78, A. G. O., April 4, 1884.

SMITH, JOSEPH R., Major and Surgeon. Directed to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to be held in Washington, D. C., on the 6th of May, 1884, and, on the adjournment of the association, to return to his proper station (San Antonio, Texas). Par. 7, S. O. 81, A. G. O., April 8, 1884.

BAILY, JOSEPH C., Major and Surgeon. Leave of absence extended three months. Par. 8, S. O. 83, A. G. O., April 10, 1884.

STERNBERG, GEORGE M., Major and Surgeon. Ordered to be relieved from duty in Department of California, and to report to commanding general, Department of the East, for assignment to duty.

MOSELEY, EDWARD B., Captain and Assistant Surgeon. Ordered to be relieved from duty in Department of the East, and to report to the commanding general, Department of the Columbia, for assignment to duty. Par. 4, S. O. 78, A. G. O., April 4, 1884.

WILCOX, TIMOTHY E., Captain and Assistant Surgeon. Ordered to be relieved from duty in Department of the Columbia, and to report to the commanding general, Department of the East, for assignment to duty. Par. 4, S. O. 78, A. G. O., April 4, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending April 12, 1884:*

BATTLE, S. W., Passed Assistant Surgeon. Ordered before Retiring Board.

WELLS, H. M., Surgeon. Detached from Naval Hospital, New York, to report at bureau for special duty.

HIBBETT, C. T., Passed Assistant Surgeon. Placed on waiting orders.

STEWART, H., Surgeon. Placed on retired list from April 10, 1884.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, April 21st:* New York County Medical Association; Medico-Chirurgical Society of German Physicians.

Tuesday, April 22d: New York Dermatological Society (private); New York Surgical Society; Jersey City Pathological

Society; Medical Societies of the Counties of Putnam, N. Y., Hunterdon, N. J., and Litchfield, Conn.

Wednesday, April 23d: New York Pathological Society; American Microscopical Society of the City of New York.

Thursday, April 24th: New York Academy of Medicine (Section in Obstetrics and Diseases of Women and Children); Harlem Medical Association (private); Brooklyn Pathological Society.

Friday, April 25th: New York Society of German Physicians (private); Yorkville Medical Association (private).

Saturday, April 26th: New York Medical and Surgical Society (private).

OBITUARY NOTES.

PLINY A. JEWETT, M. D., OF NEW HAVEN.—Dr. Jewett died in Providence, R. I., on Thursday, April 10th, after a brief illness, of pneumonia. He was born in Hampton, N. Y., in 1816, and received his literary education in Trinity College, Hartford, and his medical education in the medical department of Yale College, from which he was graduated in 1839. For many years he was attending surgeon at the New Haven Hospital, and for twelve years he occupied the chair of obstetrics in the medical department of Yale College.

During the war of the Rebellion he was surgeon of volunteers, and his services were appropriately recognized by the Government.

For the past few years his attention has been given to medico-legal matters, and his visit to Providence was for the purpose of testifying in a trial then in progress.

Proceedings of Societies.

NEW YORK OBSTETRICAL SOCIETY.

A STATED meeting was held December 4, 1883, W. M. POLK, M. D., President, in the chair.

INSTRUMENT FOR OCCLUDING THE URETER.—Dr. J. B. HUNTER presented an instrument which was devised by Dr. Silbermann, of Breslau. He was indebted for it to Dr. W. T. Bull, of this city. The President of the society had made a suggestion about a year ago that, in cases of disease of one kidney, by pressure one ureter could be occluded for diagnostic purposes. The instrument presented was intended to accomplish this object, and it could be used in either the male or the female bladder. Dr. Silbermann had been led to make the device by having a case of tumor of the bladder in which the growth so pressed upon one ureter as to produce occlusion. The instrument consisted of a catheter with a fenestra near the end, on the right or left side, according to whether the right or left ureter was to be occluded. At the fenestra was a rubber balloon, covered during the introduction of the instrument by a slide, and when in position distended by quicksilver introduced through the catheter by means of a syringe. Thus a heavy artificial tumor, as large as a small egg, was made to shut off all the urine coming from one kidney by pressure exerted upon the ureter where it entered the bladder. Experiments upon living dogs, which were afterward killed, showed that the ureter was thus completely occluded. In the human subject the quantity of urine secreted for a given time was measured and was found to be twice as great when the instrument was not used as when it was used.

Dr. H. J. GARRIGUES thought it more likely that the urine

was shut off by pressure of the artificial tumor upon the ureter along its course in the walls of the bladder than by occluding its vesical orifice.

The PRESIDENT was much interested in this subject, and had been experimenting for about six months in making an instrument for occlusion of the ureter, either in the male or the female, and he at present had hopes of success. The instrument consisted of a double sigmoid catheter for introduction into the bladder, between which and a rod with a bulb, passed up the vagina or rectum, the ureter could be closed so perfectly that, in experiments on the cadaver, it had been dilated to five times its natural diameter with injections of water without overcoming the occlusion. The distended ureter could be distinctly felt through the rectum above the point of compression. He at present had a case of bloody urine, evidently due to a lesion of one or other of the kidneys, and he expected by means of this instrument to be able to determine from which organ the hemorrhage proceeded. Bloody urine had been passed constantly during six months.

Dr. A. JACOBI thought it would be justifiable to introduce the finger into the female bladder and make pressure upon the ureter sufficiently long to collect urine from the opposite kidney, and thus determine from which organ the blood came.

The PRESIDENT said that a method which required dilatation of the female urethra was objectionable because of incontinence following, perhaps requiring an operation for its relief. It seemed to him that a vesico-vaginal fistula might be made, and a catheter introduced into the ureter, collecting the urine first from one kidney and then from the other, and that this procedure was always justifiable for purposes of positive diagnosis before undertaking so severe an operation as extirpation of a kidney for purely diagnostic purposes. In performing lithotomy, Sir Henry Thompson had made a sufficiently large opening into the male bladder to admit the finger. This had been done, as he understood, in about twelve cases, and without serious results. Such being the fact, surely the same procedure might be resorted to in order to catheterize the male ureters, especially in view of the inefficient methods now at our disposal for making a diagnosis in cases of unilateral renal disease.

VAGINAL HYSTERECTOMY.—Dr. P. F. MUNDÉ said that about six weeks ago he presented to the society a uterus which he had removed through the vagina for cancer of the cervix. The patient at that time was doing well, and she had continued to do well since, leaving the bed on the fourteenth day and the hospital about the sixth week. She considered herself well three weeks after the operation. Since then he had done a similar operation on another patient, but not with such fortunate results. The case presented some points of difference from the first, to which he would briefly allude. The patient was thirty-one years of age, and had had one child several years before. She was of small stature and had a narrow vagina. The uterus was movable and could be drawn down to the vulva, but it was not so freely movable as in the first case. The disease was a carcinoma of the cervix, which had very slightly encroached upon the wall of the vagina. The physician who had had the kindness to send the patient to him said that he saw her six months before, when there was a laceration of the cervix, with granular degeneration of the anterior lip, which, however, was not believed to be malignant in character. When Dr. MUNDÉ saw the patient there was no question as to the nature of the disease. The degeneration had extended as high as the internal os, but the body of the organ was not believed to be involved. At first the case seemed to be a simpler one than the former, and it was his intention only to remove the cervix; but, on the strength of the other case, which had given such brilliant results, he put the question to the patient and her husband as to

whether they were willing to take the chances of removal of the entire uterus, should it be deemed advisable at the time of the operation. They gave their consent. He was assisted in the operation by Dr. Garrigues, Dr. Chamberlain, Dr. Lee, Dr. Gerster, and the house staff. The operation proved much more difficult than in the first case, and for two reasons, namely, narrowness of the vagina, and less mobility of the uterus, the ligaments of which were tense and inelastic. The ligature was first applied to the left broad ligament by Dr. Gerster, and, as was thought, was tied very securely; but, when the ligament was divided, very slight traction upon the ligature caused it to slip. No hemorrhage, however, followed, and he proceeded to apply the ligature to the right broad ligament in sections, after which the left was also secured and ligated in sections. Perhaps an hour had elapsed, and it was then noticed that considerable oozing had taken place into the peritoneal cavity, more than had been appreciated, and the question arose as to where it came from. As he had just remarked, hemorrhage had not occurred from the ligaments. The Sims's speculum, which had been used, was removed, and immediately there spurted up two streams coming from arteries of the size of a darning needle which lay in the gaping incision in the posterior vaginal wall. The oozing from the raw surface between the vaginal wall and the peritonæum, as much as three inches in diameter, must have been considerable during the operation, but it was impeded by the pressure of the speculum, and was also hidden from view thereby. The two bleeding points could be secured only with difficulty, and the ligatures included considerable of the tissues surrounding the arteries. He brought the peritoneal and vaginal edges together with sutures, a flanged drainage-tube was inserted, and cotton packed lightly into the vagina. The pulse had flagged considerably, but hypodermic injections of whisky were given, and the patient regained consciousness, but died at the end of forty hours. The temperature rose just before death to 104° F. It was believed that the patient died from the shock and loss of blood during the operation, the greater portion of the hemorrhage being from the two arteries concealed, and partially compressed, by the speculum. There were certain points in the case from which we might derive instruction in vaginal hysterectomy. First, in cases in which the vagina was of small size, the patient not having borne children, or from other cause, it should be dilated gradually by means of the colpeurynter before proceeding with the operation; and, secondly, the uterus should be rendered freely movable several days or more in advance by gently dragging it down with a volsella. Heretofore he had employed the sharp needle in passing the ligatures through the broad ligaments, with the result of badly pricking the finger used as a guide. Hereafter he would employ the aneurysm needle and avoid this accident. It was possible that the dorsal position, with or without the use of perineal and vaginal retractors, would prove the better one for the operation, if the intestines did not fall too much into the posterior cul-de-sac.

Dr. GARRIGUES inquired of Dr. MUNDÉ why he regarded the case as one of epithelioma of the cervix.

Dr. MUNDÉ admitted that a microscopical examination had not yet been made, but he had seen so many cases of carcinoma of this part, while there had been but few cases of sarcoma of the cervix recorded, that he had no hesitancy in pronouncing the disease carcinoma in the present instance.

Dr. GARRIGUES said that at the last meeting of the society he referred to the fact of having himself been cognizant of three cases of sarcoma of the uterine cervix occurring within a year, and it was probable that more cases would be found if a microscopical examination were always made in so-called cases of epithelioma.

Dr. C. C. LEE desired to know upon what ground Dr. Mundé proposed to pursue hysterectomy in these cases, assuming that the disease was not sarcoma. He had had an opportunity to see the operation done in the present instance. It was done well, and he did not mean to express doubts as to the propriety of it in this particular case, but he wished to be more convinced than he now was of the value of an operation which at best was exceedingly difficult to perform, was extremely dangerous to life, and, if it did not prove immediately fatal, was done for the removal of a disease that was almost certain to return and destroy life in a comparatively short time.

Dr. MUNDÉ replied that the question was one which was at present agitating the surgical gynecological world: As to whether we were justified in extirpating the cancerous uterus under any circumstances, even with the prospect of the patient's recovering, for in most of the cases the disease would recur. But, inasmuch as permanent relief was thus sometimes given from cancer, grant that the operation was a justifiable one, in what class of cases should it be done? With regard to the two cases related, in the first one the disease was not found to extend above the cervix, and he must admit that excision of the cervix might have been sufficient. In the second case, he had not examined the specimen to know whether the disease had invaded the body of the organ, but this point could not be decided during life, and, in view of the success obtained in the previous case, he had felt justified in giving the patient the benefit of the doubt by removing the entire organ. In future he would limit the operation to cases in which the disease had extended up as high as the internal os, and in such cases he believed that Schroeder's method should not be undertaken, for, as shown by Schroeder's own statistics, the disease almost always returned within two years.

Dr. MUNDÉ said that if the malignant disease did not involve the vaginal walls, and extended as high up as the internal os, he would, as the question at present stood, continue to do vaginal hysterectomy, but he would emphasize the importance of mobility of the uterus and a well-developed vaginal canal.

Dr. LEE said that inasmuch as in all probability in ninety-nine cases in a hundred the disease would return, and since removal of the cervix alone would often tide on the case for a number of years, he had thought it important to know exactly under what circumstances Dr. Mundé would prefer to do hysterectomy. Several cases had been reported to the society in which removal of the cervix by means of excision and the actual cautery, and also by other means, had prolonged life several years; one had been reported by Dr. Noeggerath of a patient who was living six or eight years after the operation. The disease had extended up to the internal os.

Dr. MUNDÉ remarked that we were all familiar with the operations of Sims, Simon, and others, but the cases in which these operations for partial removal of the cervix were suitable seldom came under notice early enough for the radical operation, and there would thus still be some cases left for vaginal hysterectomy when the disease was detected in its beginning.

Dr. LEE remarked that, if Dr. Mundé could differentiate sarcoma from carcinoma positively, he would admit that he would have an indication for hysterectomy.

The PRESIDENT asked Dr. Mundé if, supposing he had a case exactly in the condition which he had described, in which all the conditions surrounding the uterus were exactly such as he had pointed out as allowing of total extirpation of the organ, he did not think that just as good results might be obtained by dissecting up the peritonæum anteriorly and posteriorly on the body of the uterus to about midway between the internal os and the Fallopian tubes, and amputating at that point. By this

method the whole of the cervix and half the body of the uterus would be removed.

Dr. MUNDÉ said that he could not speak of the results of the proposed operation from personal experience. Schroeder latterly had done essentially the operation suggested by the President, and the percentage of mortality had been very small, but there had almost invariably been a recurrence.

The PRESIDENT said that, assuming that when the disease spread from the cervix, following its usual course through the lymphatics in the base of the broad ligaments, to the lateral pelvic glands, it always manifested itself by rigidity of the tissues in this region, the conditions pointed out by Dr. Mundé as justifying extirpation—viz.: a uterus movable, capable of being drawn down to the ostium vaginae, with no infiltration around the cervix or vagina—showed, of course, that the disease in such cases was confined to the cervix. But, granting this, it seemed to him that the operation he had just suggested as a substitute would as effectually relieve a patient as removal of the entire organ would. He did not mean to say that the disease could not involve the glands in the side of the pelvis without perceptibly thickening them, but he was simply presenting the case in the most favorable light for hysterectomy. If it were not taken for granted that the lateral pelvic glands were free from infiltration, the operation which Dr. Mundé proposed to continue to do would be useless.

Dr. MUNDÉ would challenge the statement that carcinomatous infiltration of the lymphatics around the cervix necessarily produced rigidity.

Dr. HUNTER believed that any infiltration which fixed the uterus contraindicated its removal. He believed it would be impossible, were that body fixed, to remove it safely. He had records of a number of cases in which removal of the lower half had not yet been followed by a return of the disease. The longest period was eight years, the next six years. Statistics of German operators went to show that out of a large number of cases of hysterectomy recurrence took place about as certainly and as rapidly as after the removal of the cervix only.

INTRA-UTERINE FIBROID TUMOR; REMOVAL BY THOMAS'S SPOON-SAW.—Dr. LEE related a case as follows: The patient was single, aged forty-three years; had been sick fourteen years. Her catamenia appeared at thirteen years of age. She had two normal periods, and afterward was always irregular. Eleven years ago she had hæmorrhage almost constantly, which confined her to bed. The flow was very profuse. Occasional hæmorrhages continued until the autumn of 1882, when the bleeding again became constant and profuse. During January and February, 1883, she had no hæmorrhage, but in March it recurred with great violence, the patient being confined to her bed until August. During July she had pelvic peritonitis. She was admitted to the hospital September 15, 1883. When, at this time, she came under Dr. Lee's observation, she was too weak to sit up. Bleeding occurred with every change of position. On careful examination, evident signs were found of an intra-uterine tumor in the upper segment of the uterus, and two extra-uterine or subperitoneal fibroids, the organ being of about the size of the womb at the sixth month of gestation. Every attempt was made by nutritious food and tonics to improve the general health preparatory to an operation. Iron was not given, through fear of increasing the hæmorrhage. Under this treatment the patient improved rapidly, so that a more thorough examination was undertaken in November, when the tumor of the size mentioned was found in the upper segment of the uterus, its attachment being to the posterior wall, and apparently sessile. When recently an operation for its removal was undertaken, an attempt was made to dissect up the attachments by means of the scissors, but the situation of the pedicle was such

that it was impossible to do so. Thomas's spoon-saw, with the shaft curved to a suitable form, was then employed, and with it Dr. Lee was able to detach the tumor with the loss of not more than six ounces of blood. The tumor weighed between one and two pounds. A bilateral incision had first been made in the cervix, and the tumor was pulled down with a strong volsella forceps during its removal by the ordinary saw motion with the spoon. Microscopical examination showed the tumor to be an ordinary myo-fibroma. The special interest in the case was the difficulty experienced in removal of the tumor, and the great advantage of Thomas's spoon-saw for this in addition to other purposes. The instrument with a straight shaft did not so well answer the purpose from the difficulty of manipulating it at the fundus. After the operation the uterine cavity was packed with carbolized cotton, and a tampon was maintained in the vagina.

Dr. MUNDÉ could testify to the excellence of the Thomas spoon-saw. Recently he had removed an intra-uterine fibroid as large as a fist by means of the scissors and the spoon-saw, producing very little hemorrhage. The patient made a good recovery. In that case he closed the divided cervix in the usual way, several weeks later, with success.

OVARIAN CYST; METHOD OF TREATING THE PERITONEAL WOUND.—Dr. HUNTER presented an ovarian tumor removed the week before at the Woman's Hospital from a patient sixty-four years of age, who, four years ago, first noticed slight abdominal enlargement, which had continued to increase since. The abdomen had become greatly distended and breathing was difficult. It was a question as to whether there existed simply an abdominal tumor, or whether there was in addition some ascitic fluid. The incision made was less than four inches in length. A thick sac, containing coffee-colored fluid, was first reached, and, when he was about to tie its pedicle, another cyst was seen containing perfectly clear fluid, and having a very thin wall. Between the two was the pedicle. The point to which Dr. Hunter wished to call attention was his method of uniting the peritoneal surfaces of the abdominal wall. He had noticed that a good many cases of mural abscess occurred from imperfectly united abdominal walls. In the present case he passed two silver sutures entirely through the abdominal wall, including the peritonæum, closed the peritoneal opening with catgut suture, and then closed the abdominal wound by superficial sutures of silk. The weight of the sacs and the fluid in this case was twenty-one pounds.

SARCOMA OF THE KIDNEY IN THE INFANT.—Dr. JACOBI presented a large sarcomatous tumor, involving the right kidney, removed from a child about two years of age, which recently died in Bellevue Hospital. The patient was admitted during his absence in the summer of the present year, at which time it was very much emaciated, and a tumor was recognized in the right side. It was reported that the tumor had been first recognized only a week previous to admission. The growth increased somewhat in size during the next three or four weeks. The patient, however, improved a little and was less anæmic. When Dr. Jacobi saw the patient, the 1st of October, there was a large tumor in the right side, over which there was dullness on percussion, extending from the region of the right kidney downward and forward. Between this tumor and the liver he was able to discover an area of about half an inch of tympanitic resonance. The physical signs, and the fact that the child had somewhat improved, pointed rather to sarcoma than to carcinoma. The abdominal veins were considerably enlarged, and the patient suffered a good deal from dyspnea. On the 2d there existed a slight amount of pneumonia on the right side, and on the 3d, there being signs of pleuritic effusion and the dyspnea becoming worse, five ounces and a half of bloody serum were withdrawn from the pleural cavity. Dyspnea was

relieved, and the child became comfortable. The tumor remained stationary for a week or two, and then grew rapidly and became softer. There had always been slight semi-fluctuation over the region of the tumor, as usual with large sarcomata, but one day during the last week of life decided fluctuation was found. Some decomposed bloody fluid was withdrawn with the exploring needle. The child died without any return of the pleuritic effusion.

The tumor had been examined by Dr. Prudden, who had kindly furnished the following report:

Report of Autopsy.—Body much emaciated. On the right side was a large, in general firm, but in places soft, tumor, filling the right side of the abdomen and bulging out its walls laterally and anteriorly. On opening the abdominal cavity, a large encapsulated tumor presented itself, nearly filling the abdominal cavity and firmly attached over the region of the right kidney, and slightly adherent to the right abdominal wall. The ascending colon ran obliquely over its lower left segment, and the remainder of the gut was crowded closely into the left side of the abdominal cavity.

On the anterior surface of the tumor the wall was thin and flaccid, and an incision opened into a cavity containing about half a pint of brownish-red fluid ofropy consistence. [Microscopical examination of this fluid showed numerous larger and smaller spheroidal cells greatly degenerated, and much granular detritus.]

The tumor was firmly adherent above the liver. The diaphragm on both sides was crowded up to the bottom of the third intercostal space. Spleen and left kidney normal. Left ureter slightly dilated.

On being removed, the tumor measured 25 cm. in length, 15 cm. in breadth, and 12 cm. in thickness.

On the inner posterior surface the slightly dilated ureter entered the tumor at a point of slight depression. It terminated in a mass of connective tissue, which was hollow, the cavity having the form of distorted calyces.

Around the above depression in the surface of the kidney was a crescentic mass of tissue about five mm. thick, which, on microscopical examination, proved to be compressed kidney tissue.

The bulk of the tumor was coarsely nodular, whitish, very soft, in most parts almost diffuent.

There were numerous small blood extravasations in various parts. Near the center of the tumor was a large blood-clot, about five cm. in diameter.

In addition to the anterior thin-walled cyst was a smaller one near the posterior surface, filled with the same brownish-red,ropy fluid. The two cysts had the appearance of having been formed by simple softening of the tumor tissue.

The stomach contained a considerable quantity of tenacious mucus.

The opening of the thorax was not permitted by the friends, but the organs were removed from below. The heart was normal. The lungs were somewhat adherent, but otherwise normal.

Microscopical examination of the tumor showed it to be a *round-celled sarcoma*.

Dr. Jacobi quoted from the proceedings of the society for 1874 and 1881, when he presented cases of sarcoma of the kidney and made remarks. In 1874 he had been unable to discover the records of similar cases. In 1881 he himself had seen several cases, and in literature he found the record of nine cases. At present, looking over his case-book, he found the record of about fourteen or fifteen cases in all of sarcoma of the kidney. It would seem, therefore, that the condition was not very rare, and that it had not been observed before simply because attention had not been called to it. The true condition had probably been overlooked in many instances, and called mesenteric tabs, etc. However, Dr. A. Seibert, of this city, was about collecting and recording the statistics of primary tumors of the kidney, and, while he met with but few sarcomata in literature, he could compile about fifty cases of carcinoma of the kidney, including a case in his own practice. Dr. Jacobi had seen but

very few cases of carcinoma of the kidney compared with sarcoma, and thought that, after all, the observations and records were too few to permit of statistical reliability.

BENJAMIN F. DAWSON, M.D.,
FRANK P. FOSTER, M.D., *ex officio*,
Committee on Publication.

NEW YORK CLINICAL SOCIETY.

Meeting of January 25, 1884.

W. H. KATZENBACH, M.D., Chairman for the evening.

DILATATION OF THE STOMACH TREATED WITH IRRIGATION.—Dr. BEVERLEY ROBINSON showed a boy, seventeen years old, who had suffered from dyspepsia of an obstinate and distressing character, and had failed to receive permanent benefit from treatment of various sorts before being admitted into St. Luke's Hospital, where he came under Dr. Robinson's care. The following written history of the case had been furnished by Dr. Samuel T. King, of the hospital:

R. W., aged seventeen, an errand-boy, was admitted November 9, 1883. His family history was good, and he had never had rheumatism or any acute disease, nor had he been addicted to alcohol, but he had been a hasty and irregular eater. Two years ago he began to have pain on each side of the umbilicus, but none in the epigastrium. In a short time he began to vomit after eating his supper, but seldom did so after the other meals. The vomiting has continued. What he vomits now consists of mucus, never with any blood. He has no headache, and there are no cardiac, renal, or pulmonary symptoms. He suffers considerably with eructations, his appetite is poor, and he complains of numbness in the hands and feet. His bowels are constipated, and the stools are lead-colored. Pulse, 90; temperature, 98.8° F. The stomach is found to be dilated. Nothing abnormal is found about the urine.

November 10th.—Ordered \mathcal{R} Acidi carbolici, liq. iodinii comp., $\bar{a}\bar{a}$, gtt. j; glycerin. \mathcal{J} ss. M. S. Cap. haust. tal. 4ta qu. hora.

13th.—From this date to January 20, 1884, the patient's stomach has been irrigated every day with warm water containing about fifteen grains of borax to the pint, the washings being repeated until the fluid came from the stomach fairly clear.

15th.—As he vomits all ingesta, he is allowed nothing by the mouth, but is directed to have a nutrient enema three times a day. Each enema contained an egg, a tablespoonful of brandy, milk, and a little laudanum.

17th.—There is obstinate constipation, and he passes hard, scybulous masses. Ordered a daily enema containing a fluidrachm of oxgall, four fluidounces of glycerin, and eight ounces of water.

19th.—Ordered one drop of liquor potassii arsenitis three times a day.

22d.—He has been given two fluidounces of pancreatized milk every two hours, while awake, and his diet was gradually increased until he began to vomit again, when he was again placed on the use of peptonized milk. From the 12th of December to the 1st of January he was allowed scraped beef in small amount. At the latter date he was taking a variety of food, mainly nitrogenous. The nutritive enemata were stopped December 17th. On the 2d of December the carbohc acid, iodine, and arsenic were discontinued, and he was ordered five drops of tincture of nux vomica three times a day, the latter being continued for nine days. On the 20th of December he was again ordered a mixture of carbohc acid and iodine, and there was no vomiting after the 22d.

January 20, 1884.—The iodine and carbohc acid are discontinued, and he is ordered ten grains of bismuth, five grains of powdered cubebs, and one twelfth of a grain of ipecac three times a day. After this date the irrigation of the stomach was practiced only every other day.

25th.—He weighs 111 pounds, an increase of eight pounds during the last five weeks.

Dr. E. G. JANEWAY had employed irrigation of the stomach in a number of cases. Some of the patients had been benefited by it, and some had been made worse. He thought that equally good results might be obtained by putting the stomach absolutely at rest and employing rectal alimentation. The good effects of this latter method had been strikingly illustrated in the case of a patient recently seen by him, in which the symptoms were highly suggestive of cancer of the stomach—there had been hæmoptysis and a reduction of weight from 180 to 115 pounds. He thought there was stenosis of the pylorus, perhaps of a spasmodic nature. The patient was put upon his back and rectal alimentation was employed for ten days, followed by ordinary treatment, and he had now regained his 180 pounds and was as well as ever. He (Dr. Janeway) had often found that the washing out was very grateful to patients, but in nervous women it frequently caused fainting. The symptoms of dilated stomach were often present when there was no opportunity to verify the diagnosis by post-mortem examination. On the contrary, the condition was sometimes found post mortem when it had not been suspected during life. In the case of the patient shown, there was evidently some catarrhal process present.

EMPYEMA.—Dr. W. H. KATZENBACH showed a patient with the following history:

James McC., aged thirty-six, a native of Ireland, a horse-car conductor, of good family history, had never been sick until February, 1878, when he took cold, and had cough and expectoration, which continued through the summer without improvement. He lost flesh, and grew weaker. In October he was seized with sudden, sharp, dagger-like pain in the epigastrium, shooting toward the right nipple, and making respiration very difficult. Fever of ten days' duration followed, and dyspnea on exertion succeeded this. Cough and expectoration of "white phlegm" and great shortness of breath had persisted up to the time of his visit to me.

Physical examination revealed flatness over the whole right side of the chest. The heart was displaced to the axillary line. The first aspiration was performed March 29, 1879, and 138 ounces of sero-pus were removed. The operation was repeated as follows:

December 13, 1879.—152½ ounces removed.

October 2, 1880.—89 ounces removed.

November 6, 1881.—76 ounces removed.

October 28, 1882.—81½ ounces removed.

In November, 1882, an opening into the lung occurred, and large quantities of pus were expectorated, which state of things continued until December, when a painful swelling appeared in the right side, at the level of the eighth or ninth rib.

January 6, 1883, the tumor was incised, and a small amount of pus escaped. A probe could not be made to enter the cavity of the chest. Aspiration was performed, removing 114 ounces of dark-grayish sero-pus.

13th.—A probe having been passed through the eighth intercostal space, the opening was enlarged, and about 100 ounces of pus escaped. A large rubber drainage-tube was inserted. The operation was followed by very little febrile disturbance. The cavity was washed out daily with very dilute compound solution of iodine.

In February the capacity of the cavity was two quarts. The rubber tubing was discarded in a few days, and a flattened silver tube, two inches and a half long, was substituted for it. Through this about ten inches of drainage-tube were passed, which extended downward and forward, the extremity apparently resting on the diaphragm. The capacity of the cavity at that time was one quart.

After reading these notes, Dr. Katzenbach said: "The patient has been shown to the Clinical Society before, but I have brought him this evening to show the result of the operation. He has gained in weight, and feels perfectly well. The right side of the chest is very much contracted, and the spine is twisted. The cavity is in front, extending downward and out-

ward toward the site of the opening. The case is of interest also from the fact that the effusion has been tolerated so well and so long. I never found him with a temperature above normal until after the radical operation, and then only for a few days. On this account it was delayed until spontaneous opening threatened."

Dr. JANEWAY called attention to the danger of using anesthetics in operating for empyema, particularly where there was perforation of the lung. He had known of two deaths from asphyxia due to their employment.

Dr. ROBINSON thought no good came of postponing operation so long as had been done in this case, and asked the reason for its having been done.

Dr. KATZENBACH replied that the man was able to go to his work at once after aspiration, and suffered very little inconvenience.

Dr. L. WILLISTON WRIGHT believed that in some cases incision was unnecessary. He had seen a young girl, who finally recovered perfectly without it, from whom 957 ounces of fluid, in all, had been taken by aspiration.

Dr. JANEWAY said he had seen fluid from the chest very turbid from cholesterol scales. In some cases certainly operation aggravated the symptoms. In a woman who had no fever, the pulse being slow, although the heart was much displaced, an incision, made under full antiseptic precautions, had led to the development of cellulitis, and the patient had come near dying.

Dr. J. E. WINTERS said it was well known that effusions became purulent much sooner in children than in adults, but even in them absorption was sometimes seen.

Dr. L. EMMETT HOLT referred to a case, published in a recent number of the "British Medical Journal," in which the rapid absorption of pleuritic effusion had been accomplished by the hourly administration of drachm doses of common salt, together with the cutting off of all fluids. In this case there was great dyspnea with cyanosis, and the patient refused to permit aspiration. In two hours there was improvement, and in six or eight hours the cyanosis had disappeared almost entirely.

THE LESSER DEGREES OF CHRONIC PELVIC INFLAMMATION IN WOMEN.—Dr. FRANK P. FOSTER read a paper with this title, which will be published in full hereafter.

Dr. ROBERT ABBE agreed with the author as to the danger of correcting displacements with instruments. He had often felt that harm was thus done, and that little was gained. The finger was more efficacious and less dangerous. He asked whether Dr. Foster had used mercury in recent plastic exudations.

Dr. FOSTER replied that he had not.

Dr. J. H. EMERSON was not ready to say that the uterus should never be replaced by mechanical means. He was convinced of the great benefit to be derived in the class of cases under consideration from local treatment that was not operative—such as hot douches, iodine applications, local depletion, etc.—when time would allow of them.

Dr. ROBINSON thought that old pelvic adhesions, although common enough, were by no means so frequent as pleuritic adhesions, judging from what he had seen in the post-mortem room.

Dr. GEORGE L. PEABODY said that his experience was that old pelvic adhesions were exceedingly common. The majority of the bodies of women that he had examined had shown them, and in many there had been no other pelvic lesions. Quite a proportion, however, showed dilatation or a cystic condition of the Fallopian tubes in addition. He asked the grounds for the statement, so often made, that all pelvic viscera were engorged during menstruation. There was no doubt that this was the case with the uterus, but it had seemed to him to be doubtful in

regard to the other pelvic contents. Why, then, should menstruation predispose to pelvic inflammation?

Dr. JANEWAY said that, so far at least as hospital patients were concerned, pelvic adhesions were exceedingly common. Without doubt, their habits had much to do with the matter.

Dr. EMERSON thought the use of the sewing-machine ought not to be forgotten as a cause of these troubles.

KOCHER'S METHOD OF REDUCING SHOULDER DISLOCATIONS.—Dr. ABBE referred to two cases of dislocation at the shoulder in which he had used Kocher's method of manipulation with success. In one of them the heel-in-the-axilla method had failed. The bone slipped into place very readily. The dislocation was of the subcoracoid variety. In the second case it was subglenoid, and the reduction was accomplished before the manipulation was completed.

STONE IN THE BLADDER.—Dr. WRIGHT related the case of a man, thirty-six years old, who had suffered from symptoms of stone in the bladder for eighteen months. At several examinations with a Thompson's searcher the stone was easily recognized, and was usually found in the lower portion of the bladder, on the right side. It could also be appreciated distinctly through the base of the bladder when the finger was introduced into the rectum. These points were repeatedly verified by several members of the house staff at Bellevue Hospital. Lateral lithotomy was performed on the 7th of January. On making the ordinary incision, a large artery accompanying the transversus perinaei muscle (probably the artery of the bulb) was divided, and bled so profusely as to require clamping. The membranous urethra was then opened in the usual manner, and, on attempting to incise the left lobe of the prostate, the point of the knife came in contact with the stone and was arrested in its progress, the stone having apparently entered the prostatic urethra during the operation and become wedged under the staff. The calculus was then removed with forceps without incising the bladder, and the prostate was found to be uninjured. The neck of the bladder and the prostatic urethra were found to be very much dilated. The stone measured an inch and a half in length and three quarters of an inch in its greatest transverse diameter, weighed two drachms, and had the general shape of an egg, but was quite pointed at the smaller end. Its nucleus consisted of phosphates, outside of this there was a blood-clot, and around the latter there were alternate layers of urates and phosphates. The patient had an alarming hemorrhage three hours after the operation, requiring the employment of the "shirted cannula," which was left in the wound for thirty-six hours. Since then he had done well.

A NEEDLE SUPPOSED TO HAVE BEEN SWALLOWED.—Dr. HOLT showed a needle which he had removed from the buttock of a child a year old, about four weeks after the child had had some throat symptoms which had led the parents to suppose that a foreign body had been swallowed. Nevertheless, it was somewhat doubtful whether the needle had indeed gone through the intestinal canal. It was corroded.

L. EMMETT HOLT, M. D., *Secretary.*

Reports on the Progress of Medicine.

GENERAL MEDICINE.

By ALEXANDER DUANE, M. D.

THE PATHOLOGY OF DROPSY.—In a clear and satisfactory paper, Dr. T. Lauder Brunton ("Practitioner," Sept., 1893) emphasizes the fact that mere obstruction to venous return is in-

sufficient to produce oedema, unless there be at the same time increased transudation through the capillaries. Such an excess of transudation is due doubtless to increased permeability of the capillary walls, and this in turn is often occasioned by anything circulating in the vessels which tends to give the blood an acid reaction. Certain poisons, such as arsenic, act in this way; hence probably the oedema of the eyelids seen in arsenical poisoning; hence also the localized oedemas constituting urticaria and following the ingestion of irritant foods.

THE PSILLOSIS OF HOT CLIMATES.—According to Dr. G. Thin (*Ibid.*), psilosis linguae, psilosis mucosae intestini, also called "sprew," is an affection occurring in those who have been exposed to malarial influences in hot climates, and it appears to consist in a deficiency in the formative power of the lingual and intestinal epithelium.

Its prominent symptoms are diarrhoea with ultimate progressive loss of strength and death from marasmus, and sensitiveness of the tongue with a raw appearance of the latter. It is liable to relapses, and usually chronic in its course. A milk diet and the observance of hygienic precautions, with attention to the maintenance of the biliary secretion, seem to constitute the most effective treatment.

RHEUMATISM IN CHILDREN.—In the discussion on rheumatism held before the Section on Diseases of Children of the British Medical Association ("Brit. Med. Jour.," Sept. 15, 1883), Dr. T. Barlow read a long and rather elaborate paper upon the various affections associated with rheumatism, including more particularly an account of the cutaneous and subcutaneous manifestations and chorea. The latter, it may be noted, he considers to be rather a symptom than a disease. He aims to show how various may be the manifestations of rheumatism in children, and yet how closely these manifestations are related to the typical symptoms of acute rheumatism as seen in adults.

Dr. H. Ashby, in discussing twelve cases of rheumatoid trouble following scarlatina, denies the existence of a true rheumatic element in such cases. This he does on the ground of the lightness of the joint affection, the absence of cardiac complications, the presence of pyemic symptoms in two cases, and the regularity with which the articular trouble appeared at the end of the first week.

Dr. E. Rickards, in discussing the relations of chorea to rheumatism, thinks that the relation is rather one of association than causation, the chorea being dependent rather upon the depressant effects of rheumatism than upon any specific influence exerted by the latter.

Dr. J. S. Bury, on the other hand, is rather disposed to assert the more intimate relation of the two diseases.

The discussion of these papers brought out the fact that wide differences of opinion still exist among English physicians, at least, as to the relation of rheumatism to scarlatina on the one hand, and to chorea, cardiac disease, and cutaneous affections on the other. The central nervous origin of these various related affections was held probable by at least one of the speakers.

THE NATURE OF PURPURA.—Dr. S. Mackenzie (*Ibid.*, Sept. 1, 1883) believes that purpura, like dropsy, glycosuria, and other affections formerly classed as distinct diseases, should rather be considered as a symptom which may be dependent upon the most various pathological conditions. Classifying its varieties, therefore, upon a basis of causation, he considers that purpura may be either (1) vascular (hæmic), and dependent upon changes in the constitution of the blood, whether brought about by disease or by deficient nutrition; (2) toxic, dependent upon the presence of poisons in the blood; (3) mechanical, dependent upon interference with the circulation, as in cases occurring in the course of cardiac disease; (4) neurotic, dependent upon

some affection of the central or peripheral nervous system. He gives illustrations of each of these varieties. These views were in the main concurred in by Mackenzie's audience, although it was maintained by some that not every case of purpura could fairly be brought under one of these categories, and that there were instances in which it seemed to be a disease *sui generis* and not a symptom.

THE TREATMENT OF INFANTILE DIARRHŒA.—Dr. B. G. Morrison (*Ibid.*, Aug. 25, 1883) considers two varieties of infantile diarrhoea, one dependent upon indigestion of milk, the other a reflex disturbance due to dentition. The former is characterized by the presence of stools approaching the dysenteric character, very acid in reaction, greenish in color, and containing mucus. In its treatment cholagogue remedies, ipecac, rhubarb, phosphate of sodium, etc., take the most prominent place, it being premised, of course, that the undigested material is first removed by cathartics. Diarrhoea dependent upon dentition is characterized by the profuse and watery character of the dejections, and is most promptly relieved by lancing the gums and by the administration of nervines, more especially the bromide of ammonium and camphor.

TYPHOIDAL ORCHITIS.—Dr. A. Olivier ("Rev. de méd.," Nov., Dec., 1883) has been able to collect from the literature of typhoid fever and from personal experience twenty-seven cases in which acute orchitis occurred as a complication or a sequela of typhoid fever. The occurrence was noticed as long ago as 1844 by Velpeau, and has since been referred to occasionally by different authors. Various theories of its origin have been propounded, to all of which Olivier objects as either unproved or contrary to the clinical features of the disease. Thus, Vidal's theory that the orchitis is due to a thrombosis of the spermatic veins, Duffey's, that it is rheumatic in origin, Hallepeau's, that it arises from parenchymatous changes in the testicle similar to those in the liver, the spleen, and other organs, are all more or less at variance with the facts in the cases which he has examined; and the other hypotheses—that the involvement of the testicle is due to masturbation, to urethral inflammation, or to a temporary congestion of the gland, like that occurring in the parotid—are mere assumptions, unsupported by any valid evidence. The distinguishing features of true typhoidal orchitis are as follows: It comes on generally during the period of convalescence from the fever (in twenty-one cases out of twenty-seven); it is usually unilateral; it generally affects the testicle alone, less frequently the testicle and the epididymis together, and but rarely the epididymis alone (in three cases); it terminates in suppuration in nearly one fourth of the cases; it adds no gravity to the prognosis of the fever.

ACUTE ARTERITIS AFTER TYPHOID FEVER.—In an interesting article (*Ibid.*, Jan., Feb., 1884), Barié relates the symptoms and pathology of acute arteritis consecutive to typhoid fever, as observed in twenty-four cases. The affection usually comes on at the beginning of convalescence, and may occur as well in the mild as in the severe forms of typhoid fever. Barié distinguishes two varieties of arteritis, the obliterating and the parietal. In the former there is infiltration of all the coats of the artery, with roughening of the intima, and with the production of a thrombus within the vessel. The parietal variety may be regarded as an incomplete form of the obliterating arteritis, in which no thrombosis occurs. The symptoms in the former case are severe, sudden pain along the course of the vessel; diminution or suppression of the arterial pulsation; the appearance, in the part supplied by the vessel, of a swelling unattended by redness and not pitting upon pressure; lowering of the local temperature; and the presence of a cord-like feeling along the course of the artery.

This condition usually terminates in dry gangrene of the

parts supplied. [Yet in two cases of femoral thrombosis consecutive to typhoid fever observed by us in hospital practice no permanent injury resulted to the limb.] In the parietal variety the symptoms are less marked and the cord-like sensation is absent. The temperature of the part may even be elevated. The prognosis, too, is much better, the part usually recovering without the supervention of gangrene. The affection occurs oftenest in the vessels of the lower extremity (in all but two of the twenty-four cases). It is to be diagnosticated from myalgia and myositis, from phlegmasia dolens, and from lymphangitis. [In the same journal Vulpian records a case of hemiplegia and aphasia following typhoid fever, due probably to thrombosis of the middle cerebral artery, which was consequent, apparently, upon an arteritis of the kind that Barié describes.]

MICRO-ORGANISMS IN TYPHUS.—Mott and Blore ("Brit. Med. Jour.," Dec. 1, 1883), in an examination of the blood of twelve typhus-fever patients, found in every case micrococci which were not present in other febrile conditions. In six post-mortem examinations the tissues of the heart were found to be degenerated and to contain colonies of micrococci. No organisms were discovered in the other tissues. In the discussion upon this paper the subject of tuberculosis and its bacillus came up, and strong evidence was adduced of the constant association of the lesions of tuberculosis with the specific micro-organism, and of the diagnostic value of the latter.

TYPHUS IN CHILDREN.—Tompkins (*Ibid.*, Dec. 15, 1883) says that the typhus fever of children differs from that of adults mainly in the less pronounced character of the initial symptoms, the lower range of the temperature, the absence of active delirium, and the very great degree of lethargy and stupor usually present. Upon the latter symptom he lays especial stress, saying that the stupor is often as deep as that produced by a narcotic poison. The eruption also is less characteristic than in adults. Moreover, the course is shorter, convalescence more rapid, and the prognosis more favorable than in the case of adults.

SYMPTOMATIC OR BACTERIAL ANTHRAX.—Arloing, Cornevin, and Thomas ("Rev. de méd.," Nov., 1883, Jan., 1884), already well known for their researches upon charbon and its prevention by inoculation, have recently carried on experiments upon a large scale, and have arrived at very important results. They show that, out of five hundred animals inoculated by intra-venous injection of the natural virus, not one contracted the disease, and, in consequence, the mortality in the districts in which inoculation was practiced was much diminished. It is not certain, although probable, that inoculation with virus "attenuated" by heat is as efficacious as the intra-venous injection of natural virus.

HEMICHOREA DUE TO CEREBRAL LESIONS.—Mabroux (*Ibid.*, Dec., 1883) relates an interesting case in which hemichorea resulted from an apoplectic lesion of the internal capsule at its posterior portion, and on the opposite side to that affected during life by the choreic movements. This situation corresponds to the region marked out by Charcot and Raymond as the hemichoreic center. In addition, there was a condition of chronic meningo-encephalitis which had evidently long antedated the lesion of the internal capsule; and, as there were none of the usual factors present which would conduce to the production of apoplexy in the latter region, the author believes that this central lesion was consecutive to the irritation excited by the constant presence of peripheral meningeal disturbance.

THE PERIPHERAL ORIGIN OF LOCOMOTOR ATAXIA.—Page ("Brain," Oct., 1883) maintains that locomotor ataxia may sometimes have a peripheral origin, and, in support of this view, describes a case in which a painful ulcerating corn on the foot was the starting-point of degenerative changes in the peripheral

nerve fibers—changes which ultimately affected the cord itself and produced well-marked symptoms of ataxic disease.

LOCOMOTOR ATAXIA FOLLOWING DISEASE OF THE BLOOD-VESSELS.—Buzzard (*Ibid.*, Jan., 1884) gives a carefully written and very minute account of the symptoms and the autopsy in a case of locomotor ataxia in which the starting-point seemed to be in the vessels of the membranes and substance of the cord [periarthritis]. He suggests that the lesions of the optic nerve which are most marked toward the periphery may so originate, disturbances of nutrition affecting the nerve fibers and dependent upon altered blood-supply being most likely to occur in the terminal fibrils of the nerve.

THE RELATIONS OF PHTHISIS AND ALBUMINURIA.—Dr. C. T. Williams ("Brit. Med. Jour.," Dec. 29, 1883), in pointing out the connection between albuminuria and pulmonary phthisis, gives a summary of sixteen cases of phthisis in which albuminuria was present. With the albuminuria, which was generally very marked, there was very great diminution in both the absolute and the relative amount of urea (in one case to one tenth of the normal quantity). In spite of this great falling off in the amount of urea, none of the severer symptoms of uræmia were present. The temperature was in general lower (by about 1° F.) than in cases of phthisis of similar intensity uncomplicated by albuminuria, although the daily range was about the same in both sets of cases. This depression of the temperature the author ascribes to the retention of poisonous urinary constituents in the blood, and recalls the observation of Stolnikoff, who found that the pyrexia due to septicæmia and other conditions could be averted by compressing the renal arteries. The prognosis in cases of phthisical albuminuria is in general very bad, the patient often succumbing within a few weeks or months after the development of this symptom. In twelve of the cases autopsies were obtained, and in seven of these the kidney was found to be in a state of amyloid degeneration, while in three others the presence of amyloid material was uncertain; and in only two was the absence of the latter proved.

THE USE OF COW'S-MILK KUNYSS AS FOOD FOR INFANTS.—Ponomareff ("Arch. f. Kinderheilk.," v, 1, 2, 1883) believes that, while artificial kunyss, prepared from cow's milk, is of service in the treatment of many cases of infantile intestinal catarrh, it can not be used for any length of time as an exclusive article of diet; and, further, that poorly nourished children under the age of one month bear its administration badly, and suffer disturbances of digestion from its continued use.

THE MALIGNANT COMPLICATIONS OF SCARLET FEVER.—Hesselbarth (*Ibid.*, v, 3, 4, 1884) gives statistics of the results of post-mortem examination in eighty-one cases of scarlatina. These were taken from the records of the Pathological Institute in Berlin, and included all the cases of death from this cause occurring among 14,000 deaths from all causes. Of these eighty-one cases, fifty-nine occurred in children under the age of ten, and the maximum number of patients appeared to be between the ages of four and seven. The majority of deaths took place during the autumn months.

Of complications affecting the serous membranes there were found two cases of pachymeningitis, two of pericarditis, two of peritonitis, and eighteen of pleurisy. Four cases of purulent inflammation of the joints were observed. Miliary hæmorrhages under the skin or serous membranes were found in seven cases. Diphtheritic affections were present in forty cases, and included diphtheritic inflammation of external wounds and diphtheritic ulceration of the stomach, as well as the more common diphtheria of the pharynx, the larynx, the conjunctiva, and the nares.

In fifty cases there was bronchial catarrh, which in twenty was associated with laryngeal and tracheal inflammation. Gastro-enteritis existed in twenty-one cases, catarrhal pneumonia

was found in seven, croupous pneumonia in thirteen. The spleen was hyperplastic in forty cases, while in eight there were embolic lesions, either single or multiple.

In the kidneys a certain degree of parenchymatous change was almost constant. Six times acute hemorrhagic nephritis, five times diffuse nephritis, and twice suppurative nephritis were present. In eight cases suppurative inflammation of the tonsils and pharynx occurred. Purulent or hyperplastic inflammation of the cervical, inguinal, and salivary glands was found in several cases. Phlegmonous processes in the connective tissue about the neck, or in the neighborhood of the larynx and œsophagus, were observed five times. Otitis was not present in any of the cases; a surprising result, considering the frequency with which clinical experience has shown it to follow the disease.

How to LIMIT THE SPREAD OF SCARLET FEVER.—JAHNSEN ("Edinburgh Med. Jour.," March, 1884) thinks that very much can be done in this direction by the use of warm baths nightly, the body being afterward greased with an antiseptic ointment (the one which he himself employs contains 30 grains of carbolic acid and 10 grains of thymol to the ounce), and by the regular application of a solution of boroglyceride to the throat.

If these precautions are taken at the very outset of the disease and kept up through its entire course, cases which can not be thoroughly isolated may be rendered innocuous, so far as transmission of the disease is concerned. The author adds that all cloths and bedding should be steeped in a dilute solution of carbolic acid.

THE DIAGNOSTIC AND PROGNOSTIC VALUE OF THE TUBERCLE BACILLUS.—MACKENZIE (*Ibid.*, Feb., 1884), in a paper, distinguished for the conciseness with which he presents an important series of facts, details the results of examination in seventy cases of pulmonary and laryngeal disease. A little over one half of these cases were undoubtedly instances of tuberculous disease, and in all the specific bacilli were present in the sputum. In the acute cases they were usually from three to four times as abundant as in those of chronic course. In laryngeal phthisis the bacilli were usually present in abundance, and were especially numerous in the mucus taken directly from the larynx by the laryngeal brush. So marked was this phenomenon that Mackenzie attributes great diagnostic value to this mode of examination in doubtful cases of laryngeal inflammation or ulceration. On the other hand, the absence of bacilli in the sputum in suspected cases is at least strong presumptive evidence against the existence of tuberculous disease. In Mackenzie's series of cases bacilli were absent in thirty-three, of which twenty-two were undoubtedly non-tuberculous, and the remainder, although of doubtful character at the time of observation, were proved by their subsequent history not to be of tubercular origin. Accordingly, he ascribes considerable diagnostic value to the presence or absence of the bacilli in doubtful cases, especially in the incipient stages. In common with other observers, he does not consider that much stress should be laid upon the prognostic indications afforded by the number of bacilli present, since non-febrile cases of slow course may show an abundance of bacilli, while cases of acute general tuberculosis, in which the lungs are not greatly affected, usually show very few.

records the case of a little girl suffering with chronic interstitial keratitis, who ceased attending at the institution after having been under treatment for four months, and having improved satisfactorily under the internal use of iodide of potassium and corrosive sublimate, with the occasional installation of atropine. After an absence of three months she returned, and the condition of the eyes was then such as to call for further treatment. The internal treatment was resumed, and calomel was dusted into both eyes, to reduce enlarged conjunctival vessels. On the following day she was seized with a sharp conjunctivitis of the right eye, injection of the circumcorneal zone, and vascular extension on to the cornea. There was vascular irritation of the other eye, but no actual inflammation. Mr. Pryce speculates as to the cause of the conjunctivitis. Dismissing the idea that the simple insufflation of calomel was sufficient to give rise to the trouble, and having satisfied himself that the calomel did not contain corrosive sublimate, he inclines to the conclusion that an iodide of mercury was formed by a reaction between the iodide of potassium circulating in the blood and the calomel applied to the conjunctiva. He refers to similar cases published by M. Hennequin and M. Lagarde, both of whom attributed the result to the formation of an iodide of mercury in the manner suggested. In one of their cases actual sloughing of the conjunctiva took place.

Salicylic Plaster for the Removal of Thickened Epidermis.—Dr. J. C. Ogilvie Will, surgeon to the Aberdeen Royal Infirmary, writes to the "British Medical Journal" that, having had his attention drawn to the value of Beiersdorf's salicylic plaster in the treatment of cases of thickened epidermis, by its having been mentioned by Dr. Thin, at a recent meeting of the Clinical Society of London, as recommended by Unna, of Hamburg, he (Dr. Will) employed it in the case of a man who had a peculiar affection of the dorsum of the foot, the whole fore part of which was rough, brown, and warty-looking, not unlike the hide of a hippopotamus. The overgrown epidermis was firmly attached to the underlying derma, as was shown by the occurrence of bleeding when an attempt was made to detach it, and the trouble was stated to have existed for two months. The affected part was strapped with the plaster, cut into strips, and at the end of three weeks it was found nearly cured. The application was then repeated to the portion that remained warty, and in ten days more the entire skin of the foot was perfectly normal.

Injections of Ergotin into the Spleen.—Professor Fenoglio ("Spallanzani"; "Centralblatt f. d. ges. Therapie," March, 1884) has recently made use of injections of Bonjean's ergotin into the substance of the spleen in a case of swelling of the organ which had proved rebellious to other treatment. The injections were repeated on different days, with antiseptic precautions, using five centigrammes dissolved in a cubic centimetre of hot water. A decided diminution in the bulk of the organ is said to have been the result.

TUBERCULOSIS IN HENS.—"The Journal of Comparative Medicine and Surgery" says: Professor Johnne, of Dresden ("Deutsche Land-Presse"), reports quite a number of cases of tuberculosis in hens, which were traced to their being fed by a person having the disease, and who had the habit of giving the hens meat which she had chewed up for the juices. She was very fond of the hens, and in summer weather they would congregate about her, and frequently would pick up the sputa which she had coughed up. The liver, kidneys, and intestines were mostly affected.

THE PASSENGER SHIP MEDICAL SERVICE BILL.—Under the title of "a bill to regulate the carriage of passengers by sea," the following bill has been introduced into the Lower House of Congress by Mr. Slocum, read twice, referred to the Committee on Commerce, and ordered to be printed:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That in every steamship or other vessel carrying or bringing passengers other than cabin passengers to the United States, there shall be properly constructed and separated from other parts of the vessel two compartments or spaces to be used exclusively as hospitals, the one for the men and the other for the women, such hospitals to be located on the main deck or the deck immediately below it, and never on any lower deck, and to be in

Miscellany.

THERAPEUTICAL NOTES.—*The Danger of using Iodide of Potassium Internally and Calomel Locally at the Same Time.*—In the "Lancet" for March 29th Mr. T. Davies Pryce, of the Nottingham Dispensary,

no case less in size than the proportion of eighteen clear superficial square feet for every fifty such passengers and crew; and such hospitals shall be supplied with proper beds, bedding, and utensils, and kept so supplied throughout the voyage.

SEC. 2. That every steamship or other vessel carrying or bringing passengers other than cabin passengers exceeding, with the crew, fifty in number, and less than six hundred, shall be required to carry a duly qualified, competent, and regularly licensed surgeon or medical practitioner, and, where the number of such passengers and crew is over six hundred, a junior or assistant surgeon or medical practitioner in addition, which surgeons or medical practitioners, junior and senior, shall be rated as such on the ship's articles, and shall be provided with surgical instruments, medical comforts, and medicines proper and necessary for diseases and injuries incident to a sea-voyage, and for the proper medical treatment of such passengers and crew during the voyage, and with such articles of food and nourishment as may be proper and necessary for preserving the health of infants and young children; and the services of such surgeons or medical practitioners shall be promptly given without fee in every case of sickness, disease, or accident to any of the passengers or crew, or to any infant or young child of any such passenger who may require their services; and the medical officer, where there is but one, and the senior where there are two, shall also be required to perform the duties of sanitary officers, to make daily inspections of all inhabitable portions of the vessel, and daily reports thereon in writing to the master of the steamship or passenger vessel, together with such suggestions and recommendations as in his judgment may be necessary to the preservation of health on board. He shall also exercise constant vigilance in regard to the condition of the provisions and water, and promptly report to the master anything which may appear to him to be deleterious to the health of any person on board.

SEC. 3. That for the proper exercise of these functions, and the maintenance of the respect to which such medical and sanitary officers are entitled, they shall be provided with a steward or apothecary competent to dispense medicines under their direction and for their special service; and their tenure of office, remuneration, and right to suitable quarters, subsistence, and attendance shall be upon the same basis as and co-ordinate with the purser, first officer, and chief engineer of the vessel on which they serve.

SEC. 4. That for a violation of either of these provisions, or the disregard of the recommendations made in writing by the medical and sanitary officers as herein provided, the company to which the steamship or other passenger vessel belongs shall be liable to a penalty not exceeding two hundred and fifty dollars in every case.

SEC. 5. That this act shall take effect and be in force from and after its passage.

THE AMERICAN MEDICAL ASSOCIATION.—Under date of April 2, 1884, A. Y. P. Garnett, M. D., announces that the chairman of the Committee of Arrangements has accepted and approved a schedule prepared for the Section of Practice of Medicine, by the chairman of the section, Dr. John V. Shoemaker, and its secretary, Dr. W. C. Wile, of which the following is the substance:

Discussions will be held as follows, and it is stated that those who are announced to take part have consented to do so, and will be present.

1. A discussion on "A Contribution to the Clinical Study of Epilepsy" will be opened by Professor William Pepper, and continued by Dr. Roberts Bartholow, Dr. Horatio Wood, Dr. J. S. Jewell, Dr. James T. Whittaker, Dr. O. P. Hooper, Dr. Eugene Grissom, Dr. James E. Reeves, Dr. T. B. Lester, Dr. Joseph P. Logan, Dr. W. K. Bowling, Dr. John S. Moore, Dr. James F. Hibbard, Dr. J. J. Caldwell, Dr. John A. Murphy, and Dr. A. P. Grinnell.

2. A discussion on the "Clinical Study of the Heart Sounds" will be opened by Professor Austin Flint, Sr., and continued by Dr. Edward G. Janeway, Dr. William Pepper, Dr. Frederick C. Shattuck, Dr. John H. Bennis, Dr. James Wilson, Dr. Richard McSherry, Dr. James R. Leaning, Dr. John S. Lynch, and Dr. A. B. Palmer.

3. A discussion on "Tuberculosis" will be opened by Dr. Henry F. Formad, and continued by Dr. Austin Flint, Sr., Dr. William H. Welch, Dr. N. S. Davis, Dr. George M. Sternberg, Dr. R. H. Fitz, Dr. Henry O.

Marcy, Dr. James Tyson, Dr. Edward G. Janeway, Dr. Charles Dennison, Dr. Henry F. Campbell, Dr. W. T. Belfield, Dr. Alonzo Garcelon, Dr. E. O. Shakespeare, Dr. G. C. Smythe, Dr. Harold C. Ernst, Dr. W. E. Geddings, Dr. Trail Green, and Dr. John Lynch.

Papers have been promised as follows: Dr. S. G. Ayres ("New Theory and Instrument of Diagnosis"); Dr. Roberts Bartholow (subject to be announced hereafter); Dr. S. K. Crawford ("Ætiology of Enteric Fever"); Dr. Louis A. Duhring ("Dermatitis Herpetiformis"); Dr. Austin Flint, Jr. ("Dietetic Treatment of Diabetes Mellitus"); Dr. Trail Green ("The New Official Chlorate"); Dr. Gaspar Griswold ("Irregular Apoplectic Attacks from Other Causes than Hæmorrhage and Embolism"); Dr. Edward G. Janeway ("Simulation of Pathognomonic Signs and Symptoms"); Dr. S. K. Jackson ("Typhoid Fever"); Dr. A. T. Keyt ("Retardation of the Pulse in Mitral Insufficiency"); Dr. G. A. Linn ("Specific Treatment of Diphtheria and Croup"); Dr. Alexander Marcy, Jr. ("Muscular Hypertrophy of the Stomach"); Dr. Henry O. Marcy ("The Germ Theory of Disease"); Dr. J. P. Miller ("Phthisis, its Successful Treatment"); Dr. D. W. Prentiss (1. "Importance of Uniformity in the Pharmacopœia"; 2. "A Plea for Greater Interest in the Pharmacopœia on the part of Physicians"); Dr. R. Harvey Reed ("Irritation of the Capsule of Glisson"); Dr. W. L. Schenck ("Occult Causes of Disease"); Dr. James Tyson ("The Milk Treatment of Disease"); Dr. William H. Welch ("The Pathology of Myocarditis"); Dr. James T. Whittaker ("The Ætiology of Pericarditis"); Dr. James Wilson ("The Diagnosis of Tumors of the Anterior Mediastinum").

The sessions of the section will be held in Washington on the afternoons of Tuesday, Wednesday, and Thursday, May 6th, 7th, and 8th.

A CANDIDATE FOR A DIPLOMA.—A gentleman in New York (not a physician) lately received a letter from which we extract the following:

"Allow me to tax you with another matter for me, it is this, I was in the Drug business, in..... from 1833, to 36. Moved to..... Pa, 1844. Where some 12 of us, Physicians organized a *Refd. Med. ass.* and invited Dr. W. Beach, the great 'Med. Reformer,' of N. Y.—to visit, and give us a course of *Med. Lecture*, in the fall, of 46. & 47—at the close of them, gave each of us, a 'certificate' or 'Diploma,' as authorized to do by the Legislature, of N. Y. I was Pres. of that ass. While in St. Louis, Mo, some one stole them from my office, and one from the 'Hon. Col. of Phys. & Surgeons of Ohio, dated Oct. 1851. I have certificates, sworn to by the best men, that I had such certificates, some 2, or 3, years ago, perhaps longer, I wrote to Dr. Keath, Druggist, (Eclectic Pharm.), of your city, to call on Dr. W. Beach (if living), and get me a Duplicate. Dr. B. told him that he had the old Plate sent to Europe, (I think France), for a new one, & as soon as recd. he would send me one, since that time, I have not heard anything of it. Now what I wish is, for you to call on Dr. Keath, or Dr. Beach, (if he is still living), if dead, his old *Records or files*, will show when, & where, & to whom, such a course of Lectures were given, it was in Pittsburgh Pa. 1847. If nothing can be found of the above proceedings, then see the 'Gentler' of the 'Eclectic college,' of New York, city, and learn the best terms, on which I could get a Duplicate. I have Practiced the old school, & drug business for 10 years, then the 'Eclectic,' and 'Hom,' for 30 years. Was a surgeon, in the union army, and afterwards, Hospital, surg—settling up *Hosp. business* in Miss. & till 1871—and after that 'Health officer' of the city of..... Miss 10 years, in charge of, & lived in the city *Hosp.* Now would the faculty of the 'Eclectic college,' give me a Diploma, by Paying 'Graduating Fee,' I furnish all the above O. K. I can get a Diploma from other Institutions, but perfer it from there, as I have always reported myself as an Eclectic, of N. Y. I can furnish the *highest endorsements for character, and social standing*, to any *Kite. Templer* 'the enclosed card will show, 'acting'—'Capt. Genl.' of our cony, at this time. I know the college may ask an attendance of one course at college, giving credit for 2 yrs. I could not do that—am too old, 74 yrs. in May) and could not take the time. With such endorsements, or *certificate* or *Diploma*, I could secure a Possession, of *honor & profit*, a Duplicate, from Dr. Beach, would do all I want."

Lectures and Addresses.

THE CARTWRIGHT LECTURES

ON

METHODS OF STUDYING THE BRAIN,

DELIVERED BEFORE THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, FEBRUARY 2, 4, AND 6, 1884,

BY BURT G. WILDER, M. D.,

PROFESSOR OF PHYSIOLOGY, COMPARATIVE ANATOMY, AND ZOOLOGY IN CORNELL UNIVERSITY, AND OF PHYSIOLOGY IN THE MEDICAL SCHOOL OF MAINE.

LECTURE III, PART I.

(Continued from page 377.)

Some Points in Encephalic Anatomy which are not Infrequently Overlooked or Misunderstood.

For the most part, the cælian parietes are easily determined. The postcornu and præcornu are obviously circumscribed by nervous substance excepting where they join

the cella; the mesocælian walls are enormously thickened as compared with the cavity, and there is no difficulty in recognizing the floor, roof, and sides of so much of the "fourth ventricle" as directly underlies the cerebellum. But at several other places the cælian parietes lose their massive character, and are apparently—perhaps in some places really—absent, so as to leave the cavities in free and direct communication with the outside of the brain, the encephalic *enton* with its *ecton*.

Several of the points involved in cælian circumscription appear upon the mesal aspect of the brain, and their discussion may be conveniently preceded by a brief consideration of all the parts there shown.

NOTE.—The reader who is not familiar with encephalic anatomy and development will do well to consult the series of figures in Lecture I (see the journal for February 9th and 16th).

Provisional tabular arrangement of the surfaces which constitute the mesal aspect of the hemiencephalon:

A. **Entocælian**, endymal or "intra-ventricular".

B. **Pseudocælian** (serous?).—Area septalis.

FIG. 11.—MESAL ASPECT OF THE RIGHT HEMIENCEPHALON OF A CAT, DIVIDED INTO ITS FIVE SEGMENTS: $\times 1.5$. Drawn by Mrs. Gage. (See this journal for Feb. 16, p. 178.)

Abbreviations: *apx.*, auliplexus; *Ar. spl.*, Area septalis; *cn.*, conarium; *Cn. ce.*, Canalis centralis; *Cs. h.*, Commissura habenarum; *F. hmp.*, Fissura hypocompae; *Fm. Mg.*, Foramen of Magendie; *hyp.*, hypophysis; *mcs.*, mediacommissura; *mcs.*, mesocælia; *pos.*, postcommissura. The pia and arachnoidea are not distinctly represented. The heavy black line represents the cut edge of the endyma, the lining of the cella, and its divided ends are joined by dots.

The curved, heavy line extending from near the tip of the temporal lobe to the fornix really represents only one margin of the rima, that which is formed by the fimbria. To be accurate and complete, a second line, representing the torn or cut edge of the endyma covering the tenia, or whatever, in the cat, corresponds thereto, should run parallel to it, and the two should be continuous at the ventral end. With this exception, the heavy line indicates the line of division between the endymal and other surfaces, between the entocælian and ectocælian surfaces of the brain. The irregularly oval area bounded, in the figure, by the rima, and the fornix and termina, and on which are printed the words *fornix*, *auliplexus*, *crista*, and *rima*, really represents an oblique cut surface, the plane of the section by which the dien (thalamus) was separated from the part of the proen (striatum) with which it was directly continuous. Beginning with the myelocal Canalis centralis, all of the encephalic cavities are represented, but only their dorso-ventral dimension can be indicated. The diacælia embraces the space dorsad of the mediacommissure as well as that which is ventrad. The lateral portions of the procele are, of course, concealed within the hemispheres, and not even the porta can really be seen from the meson. The aulæ, however, the mesal part of the procele, certainly constitutes the narrow space between the mediacommissure and the crista, and contains the auliplexus.

In the absence of shading, the various divisions of the ectocælian surface are not easily distinguished, but, in general, excepting with the proen, a single line etad of the heavy line representing the endyma indicates both the ectal margin of a cut surface and the cut edge of the investing pia, as, e.g., with the cerebellum and the diencephalic portion of the crus cerebri. Where there are two such lines, as, e.g., at both the dorsal and ventral sides of the meson, the one nearer the endymal line limits the cut surface and represents the divided pia, while the space between it and the ectal line represents the more or less curved and retreating, natural contour of the part. These surfaces and the mesal aspect of the hemisphere (excepting as otherwise specified in the accompanying Table) are covered by the vascular pia, which also dips into the fissures so as to cover the integumentary surfaces, and passes between the dorsal aspect of the dien and the ventral surface of the overhanging proen as the *velum* (*interpositum*). For the most part the pia itself is covered by the *arachnoidea*, which, however, does not follow the velum or the integral folds, and stops a little dorsad of the callosum. In an absolutely complete figure of the meson, therefore, at least the cut edges of those two membranes should be represented. The ragged line from the rostrum to the chiasma indicates approximately where the pia was reflected from one hemisphere to the other at the cephalic margin of the pseudocæle. The slightly curved line dorsad of the mediacommissure (*mcs.*), and running cephalad from the Commissura habenarum (*Cs. h.*), does not fairly represent the habena, which is really a low ridge, forming the boundary between the entocælian, mesal aspect of the thalamus and its ectocælian, dorsal surface. In a shaded figure the diatela (with the diaplexus) would appear extending dorsad and then mesad as the roof of the diacælia. The cut edge of the diatela alone now appears as a single line, as if fused with the lining endyma and the superposed velum.

The interruption of the metacælian roof at its caudal end designates the mesal "Foramen of Magendie" in accordance with the current belief in its existence; but I am not yet satisfied respecting it, as will be presently indicated.

C. Ectocœlian, or "extra-ventricular."

1. Natural. Commissura fornicolumnarum.

a. *Arachnoidal*.—Exposed surfaces of cerebrum, cerebellum, etc.b. *Pial*.—Intergyrar and part of interhemispherical surfaces.

2. Artificial or cut.

a. *Fibrous or Transcommissural*.—Callosum, chiasma, pons, postcommissura, precommissura, Commissura habenarum.b. *Cellular*.—Medicommisura.c. *Fibro-cellular*.—Medulla, optici, etc.d. *Peculiar*.—Conarium, crista, hypophysis.e. *Atrophied*.—Infundibulum, terna, Commissura fornicis (?), diatela, metatela, valvula.f. *Edges of divided membranes and plexuses*.

From the physiological standpoint, these surfaces might be divided primarily into *commissural* and *non-commissural*, but the foregoing arrangement is in accordance with the purely morphological purpose of the present course.

Endyma.—By this term is herein designated the lining of the encephalic cavities. For present purposes it is not necessary to discuss its precise nature, or whether the above word is the right one to use.* The cœlia are certainly lined throughout by something which adheres closely to the parietes, whether nervous or only membranous, and which is reflected from the parietes upon the intruded plexuses so that these latter are in the cavities only in the sense in which the kidneys and other abdominal viscera are in the abdomen. In fact, the endyma is closely comparable with the pleura and peritonæum, and, like them, consists of a parietal portion and a *visceral* portion, the two being continuous at the points of entrance of the plexuses (Figs. 29, 30, and 39).

Whatever view may be adopted as to the microscopic constitution of the endyma, its *continuity* is absolute and unquestionable, excepting—apparently—at certain points in the roof of the metacele, now to be considered.

Foramen Magendii.—It is commonly admitted that, in the adult human brain, the metatela (roof of the metacele or "fourth ventricle") presents three orifices, one mesal and two lateral, by which the cœliæ are in direct communication with the subarachnoid space.† As figured and described by Henle (iii, 2, 360, 361, Fig. 232) and by Schwabbe‡ (422, Fig. 256), the mesal is rounded and near the tip of the cœlia; the lateral are longer and irregular, and near the flocculus at each side. The former is also figured

* Whoever takes the trouble to compare the descriptions and definitions of the cœlian lining as given in standard manuals and medical dictionaries will probably—whether or not he adopts my provisional view of the matter—hope that some competent investigator may shortly determine the anatomical and historical questions involved.

† Since the arachnoidea passes directly from the dorsal surface of the meten to the caudal surface of the cerebellum, the space thus inclosed between the meten and the overhanging cerebellum constitutes a part of the "subarachnoid space." This may be understood from Fig. 14, although the membranes are not indicated. Of course, in so far as the metatela is covered by pia, the latter also must be perforated by the foramina in question.

‡ Schwabbe's "Nervenlehre" has but just been accessible to me (March 24th); otherwise earlier references to it would have been made.

in transection by Reichert (ii, 53, Taf. ii, Fig. 14) and in longisection by Quain (ii, Fig. 319), after Key and Retzius. Westbrook (I, 351) considers that the presence of an orifice is exemplified by the fact of material injected into the myelonal subarachnoid space reaching the encephalic cavities. Allen (474) and Gray (617) do not mention the lateral orifices, and the latter states that the mesal orifice "usually" occurs.

In the days of Helkiah Crooke, or even Solly, no especial surprise might attend the supposed discovery of any number of direct communications between the encephalic cavities and the exterior of the organ. Now, however, the presumption is that the cœlian parietes are continuous, and the *onus probandi* rests with those who affirm the existence of the foramina in question. Here, at any rate, is an imperfectly understood part of human anatomy.*

Pseudocœlia.—Since the "fifth ventricle" or "ventriculus septi pellucidi" is, from the manner of its development (Quain, ii, 347; Lecture I, February 16th, pp. 182 and 183), merely a portion of the interhemispherical interval which is intercepted between the callosum and the fornix, the continuity of the caudal ends of those parts closes the space completely in that direction; in man, by the extension of the rostrum toward the terna, its cephalic boundary is also completed, and the cavity, according to Quain, contains liquid.

In man, and perhaps some other mammals, the corresponding portions of the mesal walls of the hemispheres become, or remain, thin and translucent, and the morphologically inappropriate name *septum lucidum* was given to them together. Each is thus a *hemiseptum*, and in the cat their thickness is such that the adjective has no application.

To the mesal or pseudocœlian surface of each hemiseptum, Huxley (according to Flower, 13, 634) gave the name *septal area*, the technical form of what is *Area septalis* (Fig. 14, *Ar. spt.*).

Whether or not this surface is devoid of epithelium (as stated by Quain, ii, 347), it seems proper to separate it from the true entocœlian surfaces on the one hand and the ectocœlian on the other, if only to emphasize the fact that the pseudocœlia, although simulating the true cœliæ, is at no time in communication therewith.†

The existence of an opening between the fornicolumnæ dorsad of the precommissure and leading from the "third ventricle" to the "fifth" was formerly quite generally admitted, in the fœtus at least (Tiedemann, 278; Todd, iii, 675, 704), and is credited in some recent manuals ‡ (Heath,

* From the peculiar relations and adhesions of the parts, it is very easy to make artificial openings through the roof of the "fourth ventricle," and I have not yet satisfied myself as to the existence of the Foramina of Magendie in either the cat or man. In a fresh human brain, removed with great care by Mr. F. L. Kilborne, I find what seem to be natural orifices in these places, and have had them photographed; but I am not yet sufficiently certain of their boundaries to publish the figure or a detailed description.

† Perhaps this is the signification of Wiedersheim's text (p. 278), but the accompanying figure (210) distinctly ascribes to the "fünfte ventrikel" not only direct continuity with the "dritte," but also independent lateral and cephalic parietes!!

‡ Such an orifice between the columns is distinctly represented by Schwabbe (Fig. 306), but presumably through an overlooked blunder of the artist.

522, 525; Darling and Ranney, 449; Harrison Allen, 483; Gray, 639), notwithstanding explicit denials by Mihalkovics (131), Henle (162), and perhaps others. In the last edition of Quain the facts are stated correctly.

Several years ago I satisfied myself that no such communication exists in the cat or in mammals generally, and so stated on several occasions (**4**; **9**, 125; **14**, 540; Wilder and Gage, Fig. 117, Plate II, Fig. 4). Although confident, from "the nature of things," that any such orifice in man must be artificial, it is only recently that material has been at my disposal upon which I could demonstrate the continuity of the aulic parietes between the columns. Two of these preparations are shown in Figs. 51 and 52. In both, as is also the case in the cat (Fig. 14), the mesal portion of the cephalic wall of the aula just dorsad of the præ-commissure is a very thin and delicate lamina, like the rest of the terma ventrad of the commissure, and like the Commissura fornicis (in man) already described and figured. In a brain removed, preserved and dissected in the usual way, this lamina can hardly fail to be torn, and thus give rise to a belief in the presence of a normal orifice.

In this connection, and especially in view of the criticism just offered upon certain descriptions of the pseudocele, I desire to correct an error of my own. In the pub-

FIG. 49.—TRANSECTION OF THE HEAD OF A FETAL CAT: $\times 1.5$. Drawn by Professor Clieves. The plane of transection is just caudad of the crista and chiasma. The right propterus has been removed. The pseudocele is obvious.

lications above mentioned I reiterated a disbelief in the existence of any separation of the apposed hemiseptal surfaces in the cat such as would justify the admission of a pseudocele in that animal. The specimens upon which this opinion was based were alcoholic preparations of adult brains. In the transection of the brain of a nearly developed fetal kitten (Fig. 49) the hemisepta are separated by a very considerable interval, and the recent examination of a fresh adult brain discloses a perfectly distinct pseudocele. Nevertheless, I must continue to object to the way in which this cavity is represented by Mivart (B, Figs. 127, 129). Likewise, since, as shown in Fig. 14, the rostrum is much less prolonged than in man, the precise manner of circumscription of the pseudocele in the cat and the lower mammals generally requires examination.

Crista.—This is selected as an example of group *d*, because, while constantly present in the cat (see my papers, **4**, **7**, **9**, **14**, and Wilder and Gage, 476), it does not appear in the adult human brains examined by me, and has so far been observed only in the preparation represented in Fig. 50. In the cat, when fresh, it has an almost gelatinous

appearance, but becomes opaque in alcohol. It has not yet been examined histologically.

FIG. 50.—CAUDAL ASPECT OF PART OF THE FORNIX AND ADJACENT REGIONS OF A YOUNG CHILD. Drawn by Mr. Gage. The specimen is poorly preserved and imperfect, but shows (a) the *ripa* or line of reflection of the endyma upon the portiplexus and antiplexus, indicating the dorsal limit of the porta; (b) the existence of a mesal nodule apparently representing the crista of the cat, but not seen in the adult human brain; (c) the narrowness of the fornix so far as shown. The junction of the fornix with the thalami, constituting the ventral limit of the porta, is indicated by the torn surface.

Terma ("lamina terminalis s. cinerea").—This is selected as an example of group *e*. Its existence and continuity are now generally recognized, but I have never seen it represented otherwise than in section, and usually it is shown as if quite thick, whereas it is very thin and quite transparent. As constituents of the encephalic parietes, and perhaps resembling closely the earlier condition of all of them, the terma and valvula merit more attention than they are apt to receive as components of an organ devoted chiefly to mental and nervous action.

FIG. 51.—CEPHALIC ASPECT OF THE TERMA (LAMINA TERMINALIS S. CINEREA) AND ADJACENT PARTS OF AN ADULT HUMAN BRAIN. Drawn by Mrs. Gage. The terma is the convex, mesal region just dorsad of the chiasma. The shaded surfaces at the sides of the terma are cut, but are convex, instead of plane like the surfaces dorso-d of them. The word *striatum* is on the mass so named; *procellia* designates the cavity at each side, between the striatum and the corresponding hemiseptum.

Diatela, dorsal part of the diacelian parietes, or primitive "roof of the third ventricle."—In Quain (ii, 322) it is

correctly stated that "the third ventricle is roofed over by the epithelial lining of the cavities"; the implication is, however, that, but for the fold of pia constituting the velum, the roof would consist merely of the epithelium. There is no intimation of the primary existence of any proper diacelal roof, and the figure (291) of a transection of the diacele is not very distinct upon this point. In Gray (641) the epithelium is not mentioned, while in "The Anatomy of the Head" and some other works the *fornix* is described as constituting the "roof of the third ventricle." The transections by Reichert (Figs. 32-35) indicate, perhaps too distinctly, the separation of the fornix from the diacelal roof, for the presence and relations of the velum are not clearly shown. Certainly there is a general impression among medical men that the true roof of the "third ventricle" is the fornix, and that the velum and any possible epithelium are of no especial importance.

FIG. 52.—DORSAL ASPECT OF THE BRAIN OF A YOUNG RABBIT, DISPLACED SO AS TO EXPOSE THE "ROOF OF THE THIRD VENTRICLE." DRAWN BY PROFESSOR CLEAVES.

While fresh, the cerebellum was tilted caudad and the hemispheres cephalad, and the velum removed. The mesal margin of each thalamus is seen to be a marked ridge, the *habena*, and between the *habena* extends what seems to be the primitive diatela or diacelal roof, unpenetrated by the plexuses. The cephalic end of this roof covers the aula, and is hence called *aulata*, but the two are continuous, like successive portions of an artery. The diatela is shown in transection in Fig. 53.

The origin and perpetuation of this impression are to be ascribed in part to the manner in which the hemispheres are commonly torn up from the thalami, and partly to the non-recognition of the embryological facts that the mesal part of the fornix, like the callosum, is a later development; that the diacele was already circumscribed, and remains so when they are removed. It is true that in man and most of the higher mammals, in the adult state, the velum adheres closely to the primitive diatela, and sends intrusions through it in the form of plexuses; but in the frog these plexuses do not exist, in a young rabbit (Fig. 52) the diatela is seen to be uncomplicated, and even in the adult cat, by using great care, the velum may be pulled away, leaving the plexuses, of course, but without tearing the diatela from its attachments to the thalami; such a preparation was figured and described in 1881 (14, Fig. 10) and 1882 (Wilder and Gage, Pl. III, Fig. 10, pp. 460, 467, 477).

Cephalad, the diatela is attached to the fornix, and its epithelium is continuous with that which lines the aula and porte. The relations of the parts are indicated diagrammatically in Lecture I (this journal, February 16, Figs. 38, 39).

The lateral attachment of the diatela is along a line just dorsal of the habena. In the cat there is here a slight fur-

row, *Sulcus habena*, which I have not yet recognized in man. In general, however, in all mammals examined by me, the habena indicates approximately the line of continuity of the atrophied diacelal roof constituting the diatela with the hypertrophied lateral wall, thalamus. It thus also forms the boundary between the entocelal, endymal, mesal aspect of the thalamus and its ectocelal, pial, dorsal surface. This general morphological significance of the habena has been urged by me in several publications during the last four years (5; 9, 135; 12; 14, 552, Fig. 7; Wilder and Gage, 460, 479, Pl. III, Fig. 7).

FIG. 53.—DIAGRAM OF A TRANSECTION OF THE BRAIN OF A YOUNG RABBIT; ENLARGED. This shows (a) the existence of a diatela or true diacelal roof independent of the velum and the fornix, which have been removed; (b) the continuity of the diatela with the lateral walls (thalami) through the ridges (habena); (c) the non-existence of the diaplexuses at this age of the rabbit.

Is the thalamus a constituent of the procelal floor? A full discussion of this morphological question must be reserved for another occasion.* The following is a summary of my understanding of the matter:

1. In most treatises upon human anatomy a portion of the dorsal aspect of the thalamus is described as forming part of the floor of the "lateral ventricle."

2. This idea is contrary to all the facts of embryology, and of the comparative anatomy of non-mammalian vertebrates.

3. In all the mammals examined by me, excepting Primates (man and monkeys), the margin of the fornix (fimbria) is in close relation with the striatum, with only space between (rima) for the intrusion of the proplexus. Hence the thalamus is wholly excluded from the procele.†

4. The brains of apes and monkeys have not yet been examined by me with reference to this point.

5. In man the fornix is relatively narrower than in most other mammals. Its margin (fimbria) is for some distance separated from the tævia at the furrow (*Sulcus limitans*) between the striatum and the thalamus. Consequently, a part of the dorsal surface of the latter appears to enter the procele.

6. In all cases, however, the procelal endyma is continuous over the intruded proplexus, and thence to the tæ-

* The subject was presented in Lecture III as delivered, and illustrated by preparations, photographs, and diagrams. The principal drawing, however, has been mislaid and can not be replaced in time for this article; indeed, so many points are involved that a separate article would be required for its satisfactory consideration.

† This was the case even in the brain of a hydrocephalous dog (described and figured in an unpublished paper presented at the meeting of the American Neurological Association in 1882), notwithstanding the pressure which had expanded the cælie and caused the liquor cæliarum to burrow into the substance of the hemisphere.

nia and so upon the striatum.* In some preparations this endyma is easily separable from the thalamus; when it adheres thereto, the line of rupture along the shallow groove (Sulcus choroideus of Schwalbe, Fig. 290) corresponding with the margin of the fornix, constitutes one of the *ripæ*.

7. The dorsal surface of the thalamus is thus in two divisions, pial or subfornical, and subendymal. The lateral margin of the former is the furrow just mentioned; its mesal boundary is the habena or its sulcus already mentioned. The mesal surface of the thalamus is truly entocellic; the lateral portion of its dorsal surface is pseudo-entocellic; its mesal portion, like all the other surfaces, is pial or ectocellic.

8. In representations of the dorsal surface of the thalamus, the distinction between the pial and the endymal portions should be indicated in some way, and with as much definiteness as is the distinction between the pial portion of the dorsal aspect and the endymal, mesal aspect.

9. Judging from the condition of the parts in embryos and in the lower mammals, this anomalous, apparent entrance of the thalamus into the procele may be attributed to a disproportionate lateral growth of the dien, by which the fimbria and the tænia, at first separated only by the rima for the entrance of the proplexus, are moved apart, the endyma, however, extending itself *pari passu* so as to retain its continuity over the thalamus.

10. When the thalamus is described as entering into the composition of the procellian floor, some qualification should be added. Strictly speaking, such entrance might as well be ascribed to the cerebellum or a part of any other segment.

11. In order that the human anatomist may be satisfied respecting the circumscription of the procele and the real exclusion of the thalamus therefrom, he should first recognize the segmental constitution of the entire brain; second, admit that the presumption is in favor of endymal continuity; third, study the brains of lower mammals; fourth, examine the human brain by other than the stereotyped methods.

(To be concluded.)

Original Communications.

ON

DUPUYTREN'S FINGER-CONTRACTION; ITS NERVOUS ORIGIN.

By ROBERT ABBE, M. D.,

SURGEON TO THE OUT-PATIENT DEPARTMENT OF THE NEW YORK HOSPITAL.

(Concluded from page 440.)

I present now briefly a group of seven other cases:

CASE V.—A retired physician, aged sixty-one, with no acquired or hereditary gout or rheumatism, and no traumatism that he remembers, began to have a contracting band in the

* This is intimated in Quain (ii, 324), but not shown in the figure (291) upon the opposite page. That the dorsal surface of the thalamus is extraventricular is also remarked in a note by Hadlich (J, 97).

right palm one year ago—which had been preceded by occasional pain in the same site for three or four years—with numbness and tingling, which latter abated when the band con-

FIG. 6.

tracted, but the stitches of neuralgic pain would occasionally run up the forearm and arm. (See Fig. 6.) As his home was in a malarious section, he took quinine at the time and relieved his pain. But six months ago the left-hand ring-finger began to contract, and all the pain is now in that. The malady is progressing in that hand worse than in the other. He desires me to operate on him soon.

CASE VI.—W. H., a girl of seventeen. Has had since childhood a natural semi-contraction of each little finger, which she attributes to the habit of carrying a milk-pail on her fingertips, as she says a good many of the girls do in Germany and acquire the same. One year ago the right ring-finger inflamed over the back of the second joint, implicating the extensor tendon, and matter was let out. The joint was not involved, but on the palmar surface a band began to form, and has rapidly drawn down the finger until its tip lies in the palm. (See Fig. 7.) Without ether, I cut the band subcutaneously at two points over the palmar aspect of the proximal phalanx, released the finger, and nearly straightened it. Three months later there was fair power of flexion, without recontraction, and the patient was greatly pleased.

FIG. 7.

CASE VII.—A man, aged thirty-five, had never had rheumatism, though his father occasionally had it in his knees in bad weather. Four months ago he had a sprain of the right wrist, caused by shoving a case of goods. The usual periartthritis of sprains encircled the wrist and involved the palmar aponeurosis. The little finger drew down two months ago at a right angle so tightly that no stretching could extend it, showing a rigid band on the palmar surface and a lateral thickening. I divided the cord subcutaneously, and the outside lateral band, and brought the finger nearly to complete extension.

I watched him for some time, and the flexion power returned as fast as the improved condition following the sprain would allow.

CASE VIII.—Catharine S., aged sixty-five, with no hereditary or acquired rheumatism. Contraction of the palm of the left hand began two years since, with the formation of ridges and dents in the palm, without pain. Since then a ridge has formed along the course of the little-finger tendons, and cords can be felt, but are not conspicuous, along the middle and ring fingers and the thumb, also between the bases of the index and the thumb.

There has been a burning sensation in the palm, but no neuralgia.

The right hand became affected just after the left, but the contraction only involves the fascia going to the ring and little fingers.

CASE IX.—Daniel C., aged fifty-two, a butcher. Four years ago he began to have puckering of the right palm over the ring-finger tendon. For two years there had been a tingling sensation in the little-finger and the adjacent side of the ring-finger tendons, but no neuralgia. During the four years, however, there has been a sort of writer's cramp of the thumb and the

FIG. 8.

little and ring-fingers of that hand. After attempting to write for a few moments, they stiffen up and get so cramped that he has to drop his pen and pull them straight. It only comes on in writing or prolonged grasping, and never comes elsewhere. The ring and middle fingers now have palmar cords and puckered skin. (See Fig. 8.) He never had rheumatism. He can assign no cause for the trouble, and, as it does not disable him from his duty of watchman, he refuses an operation.

CASE X.—Mr. F. B., aged sixty-one. His father had gout in his foot frequently during the latter part of his life, and his sister has enlarged rheumatic joints. One brother has a drawing down of the little finger dating from two years ago.

The patient never had rheumatism, but has had the following interesting form of neuralgia: For three or four years he has had numerous attacks of pain lasting ten days or so, extending from the vertebra prominens down each shoulder and each side of the neck to the elbow, relieved by folding the arms tightly and squeezing them, or by pressing on the shoulder.

Again, every month or six weeks for the past three or four years, the intervals being longer in summer, he has had attacks of sudden neuralgia in the right palm, repeated every few minutes for several hours, generally at night, eased only by pressing the sound thumb into the affected palm. The pains have somewhat the character of those of locomotor ataxia. They have never occurred except in the right palm, and have not been dependent on indigestion, the weather, or other apparent cause.

Again, for two years past he has had occasional neuralgia at these points in the right leg and thigh, sharp at first, but disappearing in from three to six hours, recurring in two or three months, usually at night; and, lastly, he has for five years had hyperaesthesia of the back, so that after a bath, if one should rub his back with a towel, it would give him severe pain, while pressure gave none.

His spine is not tender: his nutrition is fair; and there is no evidence of locomotor ataxia.

He was treated in 1865 by the late Dr. Van Buren for secondary syphilis, but has never had a sign of it since.

His right hand shows two dense contracting bands of the ring and little fingers, drawing them over somewhat, and existing from six to seven years. The left has three contracted bands—to the ring, little, and middle fingers—in the palm, well marked, but not flexing the fingers.

He is able to support himself by light work, and will not take time for treatment at present.

To what conclusion does the study of these cases bring us?

One will notice, first of all, a decided prominence of

nervous manifestations in the majority of these cases resembling spinal reflex action, and I will venture to assume the following working hypothesis as capable of explaining fully the symptoms observed in this disease:

First, A slight traumatism, often entirely forgotten.

Second, A spinal impression produced by this peripheral irritation.

Third, A reflex influence to the part originally hurt, producing insensible hyperaemia, nutritive tissue disturbances, and new growth, shown in the contracting bands of fascia and occasional joint lesions resembling subacute rheumatism.

Fourth, Through the tense contractions, a secondary series of reflex symptoms, neuralgias, and general systemic disturbance.

If we can prove these, it will give, to my mind, an agreeable substitute for the now commonly accepted theory of gout, a blood disorder, as a cause.

The disposition of the profession is to regard any joint inflammation of an acute or subacute form as of rheumatic or gouty character—a sudden accession of lactic acid, uric acid, or other chemical irritant. I desire to call attention to the nerve theory of acute rheumatism set forth by Dr. J. K. Mitchell, of Philadelphia, in 1831 and 1833, and afterward elaborated by Froriep and Canstatt, which had for its basis a valuable series of observations on such cases as sudden seizure with articular rheumatism in patients with partial paralysis from spinal injuries, Pott's disease—with irritation of nerve roots, hemiplegia with central irritation, and finally a great number of acute rheumatism cases magically relieved by spinal counter-irritation, and depletion over the cervical or dorsal region, according to the limbs affected. This was the basis for the theory, now accepted, of hemiplegic arthropathies and those sometimes seen in myelitis and spinal tumors, and, finally, the more chronic forms of joint disease of locomotor ataxia.

S. Weir Mitchell says the local peculiarities of spinal arthropathies will not enable the most acute observer to distinguish them from ordinary types of rheumatism, while Charcot says the only clinical characteristic distinguishing them from common rheumatism of the joints is their limitation to the joints of the parts affected with palsy. Mitchell, again, says that wounds or any form of nerve lesions can produce, apparently, acute articular rheumatism.

With this new light, we must take exception to that point in the argument for the gouty origin of Dupuytren's contraction, that rheumatic attacks set in sometimes after the operation for its relief. As my Cases II, III, and IV show, the rheumatism depended on the peripheral irritation of the cutting, stretching, and forced extension, while the preceding attacks had been caused by the presence of the tight contracted palmar band.

Again, Brown-Séquard says: "The peripheric signs of nerve irritation include contraction of muscles, referred sensations, pain, burning formication, etc., and altered blood supply."

You will remember that in Case IX the patient had marked writer's cramp, with tingling sensations, during the four years of the contracted fascia. In Case VII there

was a burning sensation in the palm. In Cases I, II, III, V, and X, there were most important and aggravated neuralgic symptoms. Whether these were due to peripheric irritation of nerve filaments secondarily involved in the contraction, or to an altered central disturbance consequent thereon, each may judge for himself. But what can we say for the extraordinary relief from the rhachialgia and cervico-brachial neuralgia in Cases I and II, that had defied the most skillful treatment, but yielded at once to the removal of the peripheral cause when the bands were cut? Or the improvement in health and entire relief from articular rheumatism in the hands in Case III, during a year and a quarter since the operation?

There is in my mind little doubt that the local contraction is responsible for many of the symptoms for which it has been attributed to a gouty origin. But it will be said by the defenders of the theory, Why does it so often happen that no traumatism can be assigned to start the trouble? I would call attention, *per contra*, to the cases in which it does happen, as in the typical case No. IV, where a cutaneous laceration preceded the contraction, and in Case VII, where an arthritic sprain caused it, as well as in the very first recorded case, that of Dupuytren's wine merchant whose strained palm was the cause. We are always liable to receive pricking, violence, and over-straining here, and it may be only on the thousandth occasion that the nerve filament will be involved which will set up this trouble—just as tetanus follows in only a small proportion of nerve lesions.

Finally, the argument that the symmetry of the affection (so well shown in Case IV and others, where absolutely the same parts of each hand were contracted) goes far to prove a gouty or blood disorder loses most of its weight when we draw attention to the frequent cases of sympathetic ophthalmia. An eye that has been injured or operated on in the ciliary region is quite likely to be followed by destructive inflammation, beginning in exactly the same situation in the well eye.

Ophthalmologists agree in attributing to the ciliary nerves the transmission of irritation to the brain center, and thence reflecting it along the corresponding nerve to the same situation in the opposite eye. In the hand we see the "labor insults," or traumatisms by pressure and so on, occurring naturally on the little-finger aspect of the palm, the cutaneous supply of which is from the ulnar nerve, reflected in a few months to the opposite hand, usually in the same position. These minor injuries are mostly forgotten as soon as made, though their effects remain.

Regarding the frequent occurrence of a family history of gout in the subjects of this affection, Dr. Keen notes that, in one hundred and five cases which he finds recorded, mention was made of its presence or absence in only forty-eight, and of these it was said to be present in forty-two, absent in six. Certainly no such proportion as $\frac{4}{8}$ of the cases are gouty, or else the marked cases I have reported would have shown some verification of these statistics. It is probable, indeed, that in the fifty-six cases in which it is not mentioned it was mostly absent, and therefore unnoticed. Adams, whose experience entitles his opinion to the greatest

weight, recently adhered to his judgment of its gouty origin in discussing the paper of Mr. Noble Smith before the Royal Medical and Chirurgical Society, while Mr. Smith, who had personally looked over some seventy patients having this affection, found the evidence was against that theory. In this opinion he was indorsed by the president of the society, Dr. George Johnson. The theory of traumatism was preferred. The seventy patients examined by him were found among seven hundred elderly people of the working classes, and included all degrees of the same trouble. Mr. Adams's *clientele*, on the other hand, is among the upper classes largely, where gout is an almost universal legacy. In America, typical gout is comparatively rare, but rheumatism very common. In a word, it seems reasonable to think that, in considering any malady, be it cataract or enlarged prostate, or anything else, we should, on diligent inquiry, find a very large proportion of patients whose relatives or ancestors had been subject to rheumatism in this country or gout in England.

Mr. Noble Smith says also that "contraction of the palmaris longus was almost constantly present in his cases, and it was thought this might indicate a condition of nerve irritation." This is quite significant in view of the theory I have advanced.

The presence of sugar in the urine in some cases has recently been suggested by a French reporter as a possible cause. I have examined it in only four of my most marked cases, and find no sugar; I presume its occasional appearance may be classed with transient glycosuria, which Charcot says may come from peripheral irritation, as in burns of the surface.

The favorite method of operation is that of multiple subcutaneous incisions practiced by Adams, of London, resorting to just as many as are needed to break up the continuity of the contracted band.

Mr. Adams recently said he had been obliged to make eighteen on one hand. In Case III, I was compelled to make twenty-five before the contractions were overcome, every finger being involved, while in Case IV twenty were made in each hand.

I think the number makes little or no difference, if they are done carefully. Antiseptic dressings will protect from all danger.

From my experience, one important suggestion may be drawn. Do not keep the hand over-stretched after cutting by binding it too tightly on splints. I believe the general fascial inflammation following is due to the nerve irritation incident to this on the principle of "*ubi irritatio, ibi fluxus*," and that we should do better to keep the hand only so far extended at first as not to give pain.

I have not resorted to the method of operating practiced by Busch, of Bonn—lifting a long V-shaped skin-flap in the palm, dissecting out the contracted bands, and allowing the wound to granulate. With antiseptic precautions it would be safe and may present advantages, but I judge, from the limited experience I have had, that Adams's method leaves nothing to be desired.

THE HEALTH OF CINCINNATI.—It is said that the recent flood has improved the health of Cincinnati by cleansing the unhealthy districts.

SUPER-ALIMENTATION, ARTIFICIAL ALIMENTATION AND GAVAGE, AND THE EMPLOYMENT OF ALIMENTARY POWDERS, ACCORDING TO THE METHOD OF DR. DEBOVE.

By HENRY B. MILLARD, A. M., M. D.,

MEMBER OF THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK; VICE-PRESIDENT OF THE NEW YORK MEDICO-CHIRURGICAL SOCIETY; HONORARY MEMBER OF THE SOCIÉTÉ ANATOMIQUE DE PARIS, ETC.

(Continued from page 432.)

AMONG other cases treated by Debove at the Bicêtre were the following:

Everard, who entered the infirmary in the service of Dr. Bourneville. Extreme weakness; profuse sweats; hæmoptysis; moist sounds at the apex of each lung; expectoration daily of 200 grammes of muco-purulent matter. To-day he does not cough nor expectorate; strength has returned, and he works the entire day. Auscultation at the summit of the lung gives only a dry sound, not easy to define. The precaution was taken of having this patient photographed before his treatment, so that his appearance before and after it might be compared. Gain in weight, 10 kilogr.

Metzger, who had an attack of caseous pneumonia following acute pneumonia, in which resolution did not take place. In the two lower thirds of the right lung there was intense bronchial souffle; patient was feeble, and expectorated daily 140 grammes of purulent matter. Under the influence of super-alimentation, all the local and general phenomena disappeared, and 16 kilogr. were gained in weight in two months. Is now quite well. This is not presented as a case of tuberculosis, but is, nevertheless, one of interest.

I saw at the hospital of la Pitié, in August last, with Dr. Debove, a number of cases of phthisis which had been benefited as much as those just presented. Their histories were given me by the *interne*, and I examined the lungs thoroughly and questioned the patient in each instance.

One was that of a man with cavities in the upper part of the left lung. There had been great emaciation, crepitant râles, sweats, cough, etc. At the time of my examination the moist sounds had almost entirely disappeared, there was but little cough, and the patient was gaining flesh and strength.

Another was that of a girl about twenty-five years of age. There had been hæmoptysis, sweats, abundant mucous râles, and expectoration. These had nearly disappeared.

Among other cases than phthisis was one of chronic diarrhœa of long standing; under the treatment a cure was rapidly progressing. Another was a case of anorexia and vomiting, in an hysterical girl, who was being well nourished by the sound. I used the sound in this case myself, preceding it by *lavage*. Another, of vomiting, was the sequel of bilious fever. This patient also was nearly cured, and was taking, in addition to the powder of beef, one or two ordinary repasts daily.

After this outline of the character and effects of Dr. Debove's treatment, I will now describe more fully the character and preparation of the powder to be employed, its therapeutic and physiological effects, etc. Debove prepared it by selecting beef as free as possible from fat, separating

it from the tendinous portions, and passing it through a chopping machine, making a coarse paste, which was then spread on plates and dried in stoves at a temperature of 90° centigrade (226° F.). The beef, hardened by drying, is triturated in a mortar, and then passed through a fine sieve. The powder thus prepared is impalpable, dry, and can be preserved indefinitely, if carefully kept from humidity, and is almost without odor. To make one pound of the powder, about six pounds of fresh beef are required, and one pound of the powder is equal to at least four of pure muscular fiber. Of this, as much as 400 or 600 grammes have been given by Debove daily, the latter quantity being equal to five pounds of beef. This is *literally* super-alimentation, and, unless provocative of some disturbance, could scarcely fail to bring about all the changes attendant upon thorough nutrition. Such large quantities as 600 grammes are, however, not often attained, and only, I believe, by the sound.

Simple as its preparation seems, practically, it does not appear so. I was shown at la Pitié numerous samples made by various chemists; they were either strong-smelling, nauseous, or unpleasant to the taste; some had putrefied, and showed under the microscope numerous living organisms; one, made from horse-flesh, had a repulsive odor, but not more than one of the other preparations made from beef.

That the essentials of purity and freedom from disagreeable taste and odor are important, especially when the powders are used for direct alimentation, is evident when it is considered that they are usually administered where there is antipathy to food, with perhaps nausea and vomiting. Dr. Debove has used exclusively for a considerable time a preparation made by J. Ferré, a distinguished *pharmacien* of Paris; he considers it perfectly satisfactory, and even better than that made by himself, and I have seen no preparation equal to it. I have had a package in my possession for six months, and, although it has for two months laid open in my office, it has undergone no deterioration. I have used in my own practice about 150 boxes, each box containing eight ounces, most of which was imported at my request by E. Fougère & Co. A possible objection to its general use is the price at which it must be sold. The retail price in Paris being five francs, it has to be sold here at retail for about \$1.50. It must be considered, however, that eight ounces of the powder are equivalent to about two pounds and a half of the fillet of beef, which would not be retailed for less than fifty cents a pound. M. Ferré has recently prepared costly machinery for making it on a large scale, and the price may possibly be reduced. There are several *poudres de viande* made by reputable chemists in Paris and advertised in the French medical journals, and I am unable to say that some of them may not be as good as the *poudre de viande de Favrot* (Ferré being Favrot's successor), but at least I have seen none as good.

There is no doubt, however, should the method of super-alimentation by the powder of beef become greatly employed, that some of our manufacturing chemists at home will succeed in making an equally good powder, and, the price not being enhanced by high duties, etc., that it can be sold here as cheap as in Paris.

The prominent advantages of this powder over other substances used in super-alimentation are, first, as regards beef, raw or partially cooked, finely chopped up; this is usually repulsive to the taste, and is liable to produce tænia. Second, as regards the employment of beef juice; this is an aliment very weak in nutritive principles, and is the least nourishing portion of the beef, containing only the mineral salts, a few soluble organic constituents of the beef, and some nitrogenized compounds. The powder, on the contrary, contains all the nutritive elements. Third, the digestibility of the beef is increased by each particle being so minute as to be brought in contact with the gastric mucous membrane, and a greater secretion of gastric juice results. Again, a difficulty is experienced in giving, in certain diseases, a large quantity of food, on account of its bulk. But of this powder there can be given by the sound, with two or three quarts of milk, as much as 600 grammes, with six to ten eggs, daily. Another and great advantage is the facility with which adulterations can be detected. To test it, it is necessary only to examine the powder under the microscope with an objective of 250 to 400, when the muscular fibers, more or less torn or broken, with their longitudinal and transverse striæ, are easily recognized. Should foreign substances, as the powder of liver, lentils, starch, rice, etc., have been added, they are easily recognized. Finally, its agreeable character and the facility, under proper restrictions, with which it can be taken for a continued length of time, and its great nutritive value, which will be shown as I proceed.

I have not been adverse to the employment of other nutritive powders, but, however great their merits, I have found none suitable for artificial and super-alimentation but the *poudre de viande*. Reed, Carrick & Co. prepare a powder of casein, beef, and gluten, and, though it is carefully prepared, and though I have given it with the same precautions as Ferré's *poudre*, I have not found it in many cases easy of digestion. Among other alimentary powders may be mentioned the powder of milk, the powder of lentils (cooked), the powder of beef and lentils combined, and the Revalenta Arabica, which is composed largely of cooked lentils. Dr. Guerder, of Paris, has introduced, and recommends as superior to the beef powder, the powder of defibrinated beef's blood. Dr. Guerder's theories, mode of preparation, etc., may be found in the "Therapeutic Gazette," November, 1883, and February, 1884.

The powder of liver has been employed in the French hospitals, but its odor and flavor are objectionable.

By desiccation of beef according to Debove's method, it should lose none of its nutritive properties, but only its liquid principles, and these possess but slight nutritive value. According to the analysis of Berzelius, the flesh of beef contains 77 per cent. of water, consequently a gramme of the powder would equal about four grammes of fresh beef.

As regards the digestibility, compared with that of finely minced raw beef, Dr. Robin* made extensive experiments as to the artificial digestion of these two, and found

that the powder was digested three times as rapidly as the chopped beef. This is confirmed by Debove.

Broca ("Progrès médical," Oct. 14, 1882) says that he has shown by experiments that it is digested five times as rapidly as ordinary beef. The fine particles which compose it absolve the weak stomach, as it were, from the necessity of grinding it, its extreme divisibility facilitates the impregnation of the smallest particles by the gastric juice, and peptonization is more easily accomplished.

As to the assimilation of the powder and its furnishing the organism with nutritive principles: that both these are accomplished is shown by certain cases in which records were kept, mostly at the Bicêtre; the cases of Everard and Metzger, already given, show a great increase of weight. Numerous other cases also show this, and a notable increase in the amount of the urea excreted.

Among the cases showing an increase of urea are the following:

André (Bicêtre). Treated by Dr. Debove; had had profuse hæmoptyses, daily expectoration of 35 grammes of purulent matter; it was impossible for him to sit up an hour; now neither coughs nor raises; sleeps well; has no more sweats, and works all day. The coarse râles at apices of lungs have been replaced by dry sounds. Gain in daily amount of urea excreted at the end of ten days, 10 grammes.

Same service. A tailor. *Tuberculosis. Super-alimentation by Gavage*.—Average quantity of powder of beef for thirty-four days, about 300 grammes. The patient also took milk, and, as soon as the appetite had returned, any other food he wished. Gained in weight in thirty-four days, 3 kilogr. Urea increased from 35 to 73 grammes daily.

Simple Anorexia (Bicêtre).—Marie W., aged four years; imperfectly developed; weight 12 kilogr.; complete loss of appetite, taking food only by force. Direct administration of the powder with rum, about 10 grammes being given daily; an increase of nutrition being brought about, an appetite for other food returned. Powder administered daily, however, except at the end of two months, when it seemed to produce flatulence. At the end of ten weeks she had gained 4 kilogr., and her appetite had returned.

Chronic Diarrhea (Bicêtre).—Marie, coachman, aged sixty-six. Diarrhea had existed for eighteen months. Treatment commenced November 22, 1882. There were great debility, sweats, painful digestion, and intolerance of food. Weight, 44 kilogr. Fifteen grammes of the powder three times daily; quantity increased gradually to 90 grammes a day; no other food except a little milk at first, and afterward soup. From December 17th he took an ordinary meal daily, in addition to the powder. By November 27th the stools had gained in consistence and the sweats disappeared. December 5th the strength had greatly increased, the appetite returned little by little, and by the 17th of December he was able to take two meals daily with the other patients. Only one evacuation daily. Powder always given, but only once a day now. January 23, 1883, he was dismissed cured, having gained in weight 11 kilogr. *No medicines were given.*

Chronic Ulceration of Stomach, followed by Tuberculosis.—Carjat, aged fifty-four. Cavern in apex of left lung. Hæmatemesis, sweats, and cough. Treated by direct alimentation; sound not used. Three litres of milk, six eggs, and 180 grammes powder of beef used at first. In fifteen days the quantity of the powder was increased to 300 grammes. By this time the weight had increased one and one fourth kilogr. Six weeks

* See Robin, "Des poudres alimentaires et de l'alimentation artificielle," Paris, 1882.

later he had gained two and one half kilogr. more, and the ulcer and phthisis seemed cured.

The details of the treatment of this case, pathological conditions, etc., are of much more interest than the mere increase of weight, and, inasmuch as recoveries from diseases of a character to produce emaciation are invariably followed by increase of weight, it will not be necessary for me to present other cases illustrative of this.

The cases, however, show in a general way what may be derived from the powder when no other food can be tolerated. There may be instances in which it seems applicable where it would prove useless, but I believe that in the majority of instances in which it is appropriate it will, if properly administered, be beneficial.

Dr. Amanieux, *loco citato*, endeavors to show that the powder can always be given without the sound. That it can often be done I know from experience; but to insure the ingestion of large quantities, to *super-nourish* (*sur-alimenter*) the patient, the sound must in some cases be used. As the simplest method, however, the direct administration may at first be tried. The digestibility of the powder and the ability of the patient to tolerate it depend greatly upon the manner in which it is prepared.

The simplest expedient which can be used is evidently water. If this be employed, it should be dropped, hot or cold, upon the powder, and stirred or pressed with the spoon so as to make a homogeneous paste; the water can then be added little by little until the mixture is of the consistence of cream. If these precautions be not taken, the mixture contains numerous fine lumps, more difficult of digestion and distasteful to the patient. Powdered sugar may then be added to suit the taste, and the mixture flavored with a little rum, cognac, essence of punch, or vanilla. I have found Angostura bitters with sherry very acceptable. The mixture resulting from its preparation with milk is smoother, but, as Debove says, "there are patients who can not get down three or four times daily a bowl of cream." For such patients water may be used, a greater amount of smoothness resulting from mixing the powder first into a compact mass with the yolk of an egg. A teaspoonful or two of black coffee gives a pleasant flavor, and for children an equal part of cocoa can be added.

Patients sometimes complain that it leaves a glutinous feeling in the pharynx; in such cases a little light red wine may be swallowed. It is better to make the mixture so it can be taken in two or three swallows. All these are apparently trifling precautions (*petits soins*). It is necessary, nevertheless, to observe them.

Its use may be commenced in moderate doses, as, for instance, 10 to 25 grammes in the morning; it then serves very well the place of breakfast. Other food, however, as tea or coffee, may, if the patient wish, be taken an hour or two after it. Should the patient be unable to digest other food, as much as 300 grammes of the powder (equal to 38 oz. of beef-broth) can often be taken daily. It sometimes, however, at first produces diarrhœa, and often, where it has been taken for several days, the stomach seems to become intolerant of it and not to digest it readily. In such cases I diminish the doses, or intermit its use for a day or so; and,

where it can not be otherwise taken, I resort, if the patient's consent can be obtained—which is not always possible in private practice—to the sound. With proper care, however, I have given the powder in full doses by direct administration for several weeks consecutively. Nevertheless, there are cases where this is impossible, as we all know how the stomach tires of a uniform regimen; and then the tube becomes necessary.

I can not here enumerate more than a few of the most striking cases treated in the French hospitals, nor present more than a digest of them. Some of them, however, I will give, selecting those as varied in their character as possible, and add my own experience. In addition to the cases already presented may be cited the following:

Hysterical Spasm of the Pharynx. (Hôpital St. Antoine, service of Dr. Dujardin-Beaumetz.)—Angèle L., aged fifteen. Admitted August 8, 1882. Anorexia to such an extent that in March, 1882, no solid food could be taken, and for the last fifteen days has been unable to retain liquid food. Upon examining the patient, she was found to be greatly emaciated; there were rhachialgia, mastodynia, *clou hystérique* of the head, and cutaneous anesthesia of both sides. When she attempted to swallow pure water it was rejected by a spasm of the pharynx. The tube was resorted to, and, to the surprise of Dr. Beaumetz, entered without difficulty. The stomach being washed, 20 grammes of the powder were introduced in a little milk; no vomiting. By the 11th of August there were administered daily 300 grammes of the powder and a litre of milk, but it was not until the 16th that she could take *directly* a little milk without vomiting; she then took a cupful. (On the 14th she had the first natural movement of the bowels.) On the 24th artificial alimentation was discontinued, 150 grammes of raw beef, with two eggs, being taken. September 9th she was dismissed cured.

Locomotor Ataxia, with Vomiting. Direct Alimentation. (Bicêtre, service of Dr. Debove.)—Lépreux, aged forty-one, confined to his bed. Admitted December 27th. For several weeks severe cramps in the stomach, anorexia, and frequent vomiting of food. Seventy-five grammes of the powder were given by direct administration in one day, and well digested. To January 23d this amount has been taken daily without the least repugnance or derangement of the digestive tract. No other nourishment except a little milk, wine, and soup; patient has experienced, from the first day of treatment, none of the gastric pains. Strength has returned in a very appreciable degree.

Tuberculosis, with Diarrhœa and Vomiting. Super-alimentation by the Tube. (Hôpital St. Antoine, service of Dr. Beaumetz.)—B., a Polisher, aged twenty-seven. Admitted July 4th. For nearly a year there have been cough, night sweats, and emaciation. For several days there have been diarrhœa and vomiting, with the paroxysms of cough. No appetite; moist sounds at summit of left lung; at apex of right lung a cavity; generally diffused bronchial râles. Weight, 56 kilogr. July 6th, 100 grammes of the powder administered by the tube, with half a litre of milk; no vomiting. July 9th, a litre of milk and 200 grammes of powder given. 13th, vomiting and sweats absent. Weight, 57 kilogr. From the 19th, 300 grammes of powder, with a litre and a half of milk, daily, were given by the sound, without any inconvenience to the patient. By July 30th, in addition to the powder he took two good meals daily; has resumed work. August 5th he weighed 59 kilogr.; obliged to stop work; cough always troublesome, but much less than at first.

Tuberculosis. Direct Alimentation. (Bicêtre, service of Dr. Debove.)—Roche, aged thirty-two. Admitted November 19,

1882. Had been ill for two years. Has had evening fever, night sweats, hæmoptyses, and colliquative diarrhoeas. These symptoms all existed on admission; there were great debility, bloody expectoration, inability to sit up, and extreme repugnance to and intolerance of food. Weight, 48 kilogr. Although the minutest details of treatment are given, I will only say here that by January 23d he was able to take 200 grammes of the powder daily, together with other food, was able to work in the laboratory, respiration was better, and cough almost gone; sweats disappeared, and but little expectoration. Weight, 58.4 kilogr., a gain of 10 kilogr. in about ten weeks. The powder was given, diluted with sweetened water and with a little rum. The patient was not reported as cured.

(To be concluded.)

SARCOMA OF SYNOVIAL SHEATHS.*

By THOMAS M. MARKOE, M. D.,

PROFESSOR OF THE PRINCIPLES OF SURGERY IN THE COLLEGE OF PHYSICIANS
AND SURGEONS; SURGEON TO THE NEW YORK HOSPITAL.

DURING the past four years several cases of disease of the synovial sheaths in the sole of the foot have presented themselves to me, the nature of which I failed to comprehend, and the gravity of which I did not appreciate, till the results, which I propose to relate in this paper, afforded the data for a correct judgment as to the nature, and some help at least toward a correct diagnosis, of the affection. The disease which I propose to describe to the society must, I think, be a rare one, as I have seen only the three cases here recorded, and perhaps the best way of introducing the subject will be to describe the last case which has come under my notice.

CASE I.—A. B., a middle-aged man, apparently in excellent health, presented himself at my office during the spring of 1883 for advice concerning a swelling which had slowly developed in the sole of his foot. He said that about two years previous he began to suffer aching pain in the part which he could not attribute to any strain or bruise. The pain was principally felt when standing or after walking too far. About eighteen months ago he first noticed a fullness in the sole, most marked under the metatarsal bone of the great toe, but extending along the sole up behind, and a little distance above the internal malleolus. This extension from its original seat had taken place very slowly, and he thought was still going on. By reason of this swelling the foot has gradually become so disabled that he can scarcely walk at all without a crutch, and his sleep at night is much disturbed. He feels tolerably well in all other respects, but the condition of the foot completely disables him. On examination, a swelling was found occupying the inner half of the sole, and extending round the internal malleolus up a little distance above that prominence, where it terminated somewhat abruptly. The swelling was tolerably firm, but yielding to pressure in such a way as to convey the idea of a fluid or semi-fluid substance contained in a firm and rather tense cyst or sac. This idea was strengthened by an indistinct sense of fluctuation which could be felt at different points of the swelling, and was sufficiently distinct to have induced the gentleman who had charge of the case to aspirate the tumor. No fluid was obtained. The tissues surrounding the swelling seem to be in a perfectly normal condition, and no inflammatory features have at any time been noticed.

After a careful examination of the case I pronounced a

very doubtful diagnosis, and added a prognosis which I said might be very serious, including in the future a possible amputation, and, what I did not say to him, however, a possible fatal termination. My reasons for this gloomy prognosis were drawn from my experience in two previous cases which I now propose to relate.

For the clear understanding of what I am presenting to the society, I ought, perhaps, to recall a few points in the anatomy of the parts involved. It will be remembered that, as the tendons about the wrist and ankle pass under their annular ligaments, they are contained in fibrous canals, which hold them firmly in their position and afford them a fulcrum, if we may call it so, against which the tendons act in the varying positions of flexion and extension of the hand and foot. To facilitate the play of these tendons, the fibrous sheath is lined by a serous, or rather a synovial, membrane, which at varying points is reflected from the surface of the sheath on to the surface of the tendon. This arrangement produces the usual closed serous sac, through which the tendon, covered by its layer of serous membrane, plays with a freedom from friction which is much increased by the smooth lubricating synovia which is secreted from its free surface. In the ankle these synovial sheaths commence a little above the malleoli, and extend forward into the sole to a distance varying with the point of insertion of the tendons they accompany. The one accompanying the extensors of the foot and the flexors of the toes is, it will be remembered, rather more extensive than the rest, and passes round the internal malleolus into the sole, extending quite far forward, dividing into a compartment for each separate tendon as it goes toward the distal end of the metatarsal bone to be inserted into the phalanx. It is well known that these synovial sheaths are subject to certain diseases, in which the synovial secretion is increased and seriously altered. These diseases give us the usual swellings along the course of the tendons with which we are all familiar, which swellings may contain either pure serum, or thicker fluids variously modified, or fluid containing semi-solid particles in the shape of rice grains or melon seed, and various other modifications of concrete fibrin. All these cases present one common feature, viz., an elastic, somewhat tense swelling, which gives a feeling of fluctuation which is more or less distinct according as the contents are fluid or semi-solid, the walls of the sac thick or thin, and the distension of those walls great or slight. The recognition of a distended synovial sheath is a matter of no great difficulty, but the appreciation of the nature of its contents is not so easy. Aspiration will reveal this point in many cases, but in many others nothing but a free incision will suffice. These affections, as most of us have experienced, are sometimes difficult to manage, particularly those of long standing, when the walls of the sac have become very much thickened and the contents perhaps semi-solid. Operations upon these serous sacs have always been regarded with anxiety, because of the inflammation liable to follow their incision—an inflammation which, unfortunately, does not always confine itself to the serous membrane, but, spreading to the surrounding areolar interspaces, produces some of our most formidable cases of far-spreading suppurative cellulitis.

* Read before the New York Surgical Society, April 8, 1884.

The following cases present some features in which they differ from those which I have thus sketched, and serve, it seems to me, to suggest a modification in diagnosis, and a caution in prognosis which may possibly save a serious disappointment:

CASE II.—Frank McNair, aged forty-three, a man of good habits and apparently in excellent health, came into the New York Hospital, December 5, 1879, with a swelling on the plantar surface of the great toe of one foot. It had commenced about two years before, without any known cause, and had slowly and steadily increased in size. It was from the first somewhat painful on walking, but of late had become so serious an impediment to him that he was very desirous that something should be done for his relief. There had never been any evidence of inflammatory action about it, though it was more painful at some times than at others, particularly when he had been obliged to stand or walk on it more than usual. On admission, a softish, doughy feeling swelling occupied the under surface of the great toe, extending back into the ball of the toe, so that its posterior margin was well behind the metatarso-phalangeal articulation. It had an elastic feel, and, when pressed upon, the whole swelling became hard and tense. A feeling of fluctuation was distinct enough, but left a doubt in the mind whether it was produced by a fluid or a semi-solid material within the cyst. The cyst-wall seemed to be quite thick. The diagnosis was clear as to the distension of the synovial sheath, but the nature and consistence of the contents were not so manifest. My notes do not say that aspiration was performed, but, if it was, no information was elicited by it. The case was regarded as one of the usual forms of distension of the synovial sheath from a low grade of inflammation with effusion of a fluid which had become partially solidified by the admixture with it of some form of a plastic fibrin. I was at the time experimenting with "through drainage," and on the 6th of January I employed that method in the treatment. An opening was made into the sac as far back as possible, and the contents were with some difficulty squeezed out. The substance thus evacuated was of a yellowish-white color, looking not unlike the sebaceous contents of some of the cysts of the scalp, but it was evidently not a perfect fluid, for certain portions of what was squeezed out showed some such coherence as would be found in a soft growth which had been forced from the cavity in which it had lain, and which, though in the main broken up into a diffuent pulp, showed clear indications of its having been originally a continuous tissue, though of the softest possible consistence. Not much attention was given to this peculiarity at first, as its cohesion was supposed to be explained by the idea of the fibrous masses of which the substance was partly composed adhering more or less intimately together. It was afterward recognized that this feature was of most important significance. After emptying the cavity of all that could be forced out, the walls, as far as could be seen through the opening, presented the ordinary smooth, shining, white surface of healthy synovial membrane. An opening was now made at the anterior extremity of the cavity, and a perforated drainage-tube passed from one opening to the other. The wound was dressed antiseptically, and the ends of the tube were allowed to project through the dressing, thus allowing the cavity to be easily washed out with a weak solution of carbolic acid. No inflammatory reaction occurred. The tube was removed in about a week, and the wounds soon healed. The patient thought himself cured, and could walk pretty well before he left the hospital. Six months afterward I saw him with the swelling about as bad as before, and the impairment of motion steadily increasing. From that time I have not seen him.

The report of the pathologist on the material expressed from

the cavity was as follows: "Specimen consists only of irregular fragments scraped and torn out of what seemed to be a cyst, though the cyst-wall was not demonstrated. Microscopic examination: 1st. When examined in fresh state, there was found to be much amorphous fibrin, and tumor was thought to be a benign cyst. 2d. The fragments, when hardened, show, upon section, in some cases only amorphous fibrin, but in other cases the typical structure of spindle-celled sarcoma."

CASE III.—Delia Dalton, aged twenty-five, entered the New York Hospital, January 21, 1880, with a swelling of the sole of the foot. The history was similar to that of the other cases. She said that about two years previous she began to experience pain and soreness on walking, which she attributed to the pressure of her shoe. About eighteen months before her admission she sprained the same ankle, since which a lump appeared below the inner malleolus which has slowly increased. It has given her much pain, especially on walking. The swelling had been punctured several times. The first time a little serum flowed out, but in subsequent punctures nothing was obtained. She appeared to be in good general health, and when quiet does not suffer much from her foot. During and after walking, however, she suffers so much that she is completely disabled. The swelling occupies a large part of the sole of the foot, and extends behind and above the inner malleolus. It is softish, non-elastic, but by pressure on one part of the swelling the whole can be rendered tense. A feeling of fluctuation is perceptible, giving the idea of thick, viscid, or semi-solid contents. The tissues overlying the tumor are perfectly normal. It was clearly a case of distension of the large synovial sheath which surrounded the flexors of the toes and the extensors of the foot; but the nature of the distending material could not, of course, be ascertained. In any case, opening the sac and emptying it of its contents was the first step in any method of cure. This was accordingly done January 27, 1880. An opening was made nearly as far back as the malleolus, and through it the cavity was evacuated. Nothing flowed out when the cavity was first opened, but on firm pressure a semi-fluid substance, which exactly resembled that found in McNair's case, was with some difficulty forced out, leaving a large cavity extending forward so far that a straight steel sound passed quite to the root of the toes. The difficulty of extruding this substance was so great as to give me the idea of its adhesion to the walls of the sac. To make sure of this point, and to enable me to break up the semi-solid mass so that it could be thoroughly evacuated, I enlarged the opening till it admitted my finger. I could now recognize that there was at many points a close adhesion of the contained mass with the walls of the cavity, which were lined with a bright-shining serous membrane. The finger could now trace the division of the main cavity into several smaller chambers, which represented the prolongation of the sheath formed over each separate tendon as it went to be inserted in the phalanges. All these cavities had been enormously distended by the accumulating mass within, so that I could move my finger about through quite a large space in the middle part of the sole, and could even push the tip of it into some of the enlarged anterior digital prolongations. With the finger, and with the scoop and forceps, I evacuated the cavity as completely as I could, but I was sensible that a considerable portion of the mass was not reached, and could not by any of my contrivances be perfectly removed. The operation was completed by making an opening anteriorly near the base of one of the toes and passing a through drainage-tube from one opening out at the other. The wound was dressed antiseptically, with the ends of the tube projecting, and a solution of carbolic acid (1 to 60) was injected into and through the cavity once in every three or four hours. No inflammatory reaction followed. The tube was not removed

till February 6th. The wounds healed slowly. She was discharged improved May 4th, but, as in McNair's case, all traces of the tumor had not disappeared, and she could not walk without pain. The semi-solid contents of the tumor were very carefully examined. To the naked eye it gave the appearance of a very soft, almost diffident substance, much broken up by the violence done in removing it, but sufficiently coherent in many points to demonstrate that it was a soft tissue and not a thick fluid. The microscopic examination by Dr. Peabody showed "the typical formation of a spindle-celled sarcoma, being almost identical with the scrapings from the foot of McNair." She was readmitted to the hospital September 18, 1880. The swelling was as large as ever, and quite as painful. Her general condition was good. There was no cachexia, and no enlarged glands could be discovered. There was, however, on the opposite side of the foot, another growth which had developed since she left the hospital, and which did not appear to have any connection with the tendons or their sheaths, and also another growth in the fatty tissue covering the lower surface of the os calcis. The clinical history, taken with the microscopical appearances, so clearly pointed to extension of sarcomatous disease that amputation was advised and performed on the 9th of October, low down in the leg. She made a good recovery, and nothing has been heard from her since she left the hospital.

Dr. Peabody's report of the dissection of the foot is as follows: "Beneath the cicatrix, and extending thence backward and forward over a space irregularly circular, with a diameter of an inch and a half, is a new growth. It is very soft and friable, of a reddish-gray color, and contains numerous small spots of hemorrhage. It lies beneath the skin, and spreads thence deeply downward, involving the sheaths of the tendons. On the outer side of the foot, just below the malleolus, is another mass of similar material about as large as the end of one's thumb, which bears the same relation to the superficial and deep tissues as does the growth on the opposite side of the foot. Underneath the os calcis is a mass of the same tissue three or four times the size of the last-described mass. It invades the tissue of the bone at one point to the depth of a quarter of an inch. Just behind the ankle joint is a very small collection of material apparently similar to the other; it is not larger than the tip of one's finger. These masses of new growth are all discrete, being separated by areas of tissue to all appearances healthy. The tissue of the new growth, examined microscopically, is found to be very rich in spindle cells and in oval cells of small size, joined by a very small amount of fibrous intercellular substance."

From this it is evident that the recurrence was not confined to the synovial surface, as was the original disease, but had passed through into the surrounding tissues, and, besides, had developed in new and isolated spots, where it was not known or suspected to exist at the time of operation. This, therefore, may fairly be regarded as a case not merely of recurrence *in loco*, but one of commencing generalization, which entitles the affection to be considered as of the most decidedly malignant character.

The literature of diseases of the synovial sheaths seems to be extremely meager. A great many isolated cases of the ordinary forms are scattered through the journals, and Dr. Hulke, in the "Medical Times and Gazette," gives a short account of a case in which he found, in a post-malleolar swelling, the cavity filled with small grains, as he describes them, of the shape and size of melon-seeds; but I have not yet been able to find any description of an endogenous growth within the synovial sheaths which in any way

resembles that which we have been considering. Fournier and Verneuil have published short papers on the form of synovial distension which is dependent upon syphilis, but to this form their cases and remarks are strictly confined.

I have presented these cases to the society because I think they offer a phase of sarcomatous disease which has not hitherto been described. Beside the interest which may attach to them as rare developments of sarcoma, they have, I have thought, a practical importance in the diagnosis, and especially in the prognosis, of synovial diseases. Traumatic and spontaneous inflammations of the synovial sheaths, both acute and chronic, are certainly not very uncommon affections, and to discriminate between these comparatively harmless conditions and those in which dangerous and even fatal results may possibly be realized is worthy of careful attention. That such discrimination may be made with certainty I would not venture to claim, but I think that the slow, painless progress, at least in the earlier stages, the absence of distinct fluctuation, the firmness and tension of the sac, and the negative results of puncture, may lead to a suspicion, if not to a certainty, of sarcoma, and may thus have an important bearing both on treatment and on prognosis.

Before concluding I wish to read the following letter:

"12 WEST THIRTY-SECOND STREET, April 5, 1884.

"DEAR DOCTOR: I am not sure whether this case belongs to your cases or not:

"Male, aged thirty, a laborer. Tumor removed by Dr. Wood, June, 1869. Ten years ago patient first noticed a tumor the size of a pea in the palm of the hand. It grew slowly at first, rapidly within the last three months.

"It is now situated between the palmar fascia and the sheath of the tendons. It is of pyriform shape, six and a half centimetres long.

"When laid open, the tumor is found to consist of a fibrous cyst-wall, from which grow soft masses, filling up the cavity. These masses are soft, succulent, yellow, mottled with hemorrhages. They are composed almost entirely of cells, which are of round, oval, fusiform, and stellate shapes.

"The history as to the exact position of the tumor is not satisfactory, but I believed at the time that it originated in the sheath of one of the tendons.

"Yours truly,

"FRANCIS DELAFIELD."

NEW YORK, SATURDAY, APRIL 26, 1884.

PHYSICAL REST FOR THE BRAIN.

OVERWORK of the brain in the way of strained or unduly prolonged intellectual exertion and the subjection of the organ to the wearing effect of protracted anxiety and responsibility are now rated at something like their real significance as factors in the train of causes that but too often, in the press of our busy lives, lead on to premature decay of mental vigor, or at least to the wretched states termed "brain-exhaustion," "nervous prostration," and the like—conditions in which the brain is equal to little more than presiding over the functions of vegetative life, and is scarcely able to play even this restricted part in such a way as to maintain the normal constitution of the tissues. This element of cerebral hygiene, we say, has come to be generally appreciated by medical men, and is gradually forcing itself on the attention of the community. But what may be termed, in contradistinction to functional rest for the brain, its physical rest has hitherto been limited generally to the withdrawal of sensory and emotional sources of irritation. A grosser sort of physical injury of the organ, even mechanical in its nature, has lately been pointed out by M. Luys.

According to the "Progrès médical," this distinguished observer read a paper at a recent meeting of the Paris *Académie de Médecine*, on what he termed the "locomobility" of the brain according to different attitudes of the body. Surrounded as it is within the cranial cavity by an empty space, says M. Luys, the cerebral mass is subject to displacements of greater or less degree, as well under the influence of changes in the bodily attitude as under that of the heart's contraction. Let a man lie down or stand up, and the brain obeys the law of gravitation; in the one case the occipital end of the organ comes into contact with the bony support, leaving an empty space in front, while in the other the void occurs at the occipital region, the whole frontal portion being occupied by the anterior lobes. The movements of the brain involved in these changes of its position are of a gliding nature, by virtue of the lubricated surface of the arachnoid, and they are performed slowly and progressively, so that it would take five or six minutes for the displaced parts to return to their former situation.

Reasoning from these anatomical data, M. Luys draws important deductions as to cerebral action, both normal and pathological. By the sudden ischemia produced by the changes of position he explains the derangements that are so common in convalescents, and the sense of dizziness or confusion that results from suddenly assuming the erect posture after lying down. It is thought not improbable, indeed, that the extreme

pains of meningitis may be due to the roughening of the affected membrane opposing an impediment to the physiological gliding of the brain; and it is suggested that the attacks of giddiness, and even of apoplexy, which take place in the subjects of heart disease when they rise from the horizontal posture may be owing in great part to these changes in the position of the organ. The same influence is invoked, too, to explain the varying moods of the insane—their special intractability while lying down at night, and their calmness in the sitting posture. All sorts of commotion, repeated shocks, the jarring of a railway train, are thus capable of acting injuriously on the cerebral mass, and all the more so in the aged, especially in those whose brains have already suffered damage. As a practical application of these views, M. Luys advises against travel continued for more than a day at a time, and insists that the due period of rest in the horizontal posture should not be neglected.

It is true that, at the succeeding meeting of the Academy, M. Colin, of Alfort, brought several objections against the conclusions drawn by M. Luys, chiefly that they were based upon experiments on the cadaver, in which the conditions were different, and that an opening was necessarily made in the dura mater, whereby, in all probability, filaments were sundered that ran from this membrane to the arachnoid and served to check the movements of the brain; adding also that the venous sinuses were empty, and therefore could not perform the cushion-like office that pertained to them during life. To these criticisms M. Luys retorted that M. Colin's experiments had been performed on the lower animals, in which the conditions of the encephalic mass were quite different from what obtained in the human subject, owing to the diverse configuration of the cerebro-spinal axis. He stated, too, that he had taken pains to guard against error in regard to the sustentative action of the vessels by injecting them with a material that would solidify and give them the caliber proper to them during life. M. Bécéard gave notice that he would speak on the subject at the next meeting, and it will be interesting to observe what further facts may be brought out bearing on the question.

THE SENSES—FIVE OR SEVEN?

THE old hint that "there are more things in heaven and earth than are dreamt of in our philosophy" is one that can never long escape the inquiring mind. In its present state, science is overlapped by speculation at many points, and a suggestion having its root in the imagination often points to a line of research that leads to demonstration. Questions bringing up these reflections are dealt with by Dr. William M. McLaury, of New York, in a pamphlet bearing the title that forms the heading of this article, the same being a paper read by him at a recent meeting of the Northwestern Medical and Surgical Society.

Dr. McLaury begins his paper by pleading that he is unaccustomed to writing, and it is true that we have not known of him as a frequent contributor to literature, but on this account we think it is all the more to his credit that he has taken pains

to write out the ingenious thoughts which form the basis of his paper. And this leads us to remark that it would be well if the members of our profession would oftener communicate their ideas at society meetings, even if, they distrust their capabilities of expression.

The paper in question is short, and does not readily admit of condensation. We shall therefore content ourselves with indicating its general purport, without attempting an analysis. Starting with the assumption that the sense of touch is the basis of all the other special senses, the latter being modifications of tactile sensibility, the author thinks we may quite as well admit that further modifications of this primordial sense may be developed under special conditions, and allow an actual existence to the occult powers which occasionally seem to be vested in particular individuals, being spoken of by the terms "second sight," "spiritual manifestations," etc. A striking instance is given of the alleged action of some such faculty, and one that will come home with special force to the profession at the present time, in the following words: "For instance, J. Marion Sims appearing to Dr. Byrd at the hour of his death, saying to him, 'James the Fourth is dead.' Dr. Byrd was so disturbed that he could sleep no more, but walked the floor till morning, when a telegram announced the fact that James the Fourth (a name given to Dr. Sims by his friends on account of his being the fourth of that name in the direct line) had died just before Dr. Byrd was awakened by him."

As the author remarks, there are many occurrences of this sort on record which ought not to be ignored, however we may be disgusted by fraudulent assertions on the part of designing persons who pretend to have similar experiences. The paper is highly suggestive and ingenious, and we commend its perusal to our readers.

NEWS ITEMS, ETC.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 23, 1884:

DISEASES.	Week ending April 15.		Week ending April 22.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	19	1	10	1
Typhoid Fever	6	1	10	4
Scarlet Fever	78	17	100	13
Cerebro-spinal meningitis. . .	5	5	0	0
Measles	107	16	78	2
Diphtheria	39	22	49	18

CHOLERA IN THE EAST.—The French Government is reported to be preparing a system of quarantine and inspection of vessels arriving from infected ports, in view, it is said, of the present prevalence of the disease in India. A London dispatch dated April 23d reports the arrival of an English ship at Alexandria, Egypt, from India, with a case of cholera on board.

YELLOW FEVER AND PREVENTIVE INOCULATION IN BRAZIL.—The "Gazette hebdomadaire de médecine et de chirurgie" quotes a Rio de Janeiro newspaper to the effect that Dr. Domingos Freire's supposed discovery of the contagium vivum of yellow fever, and of the practicability of preventing the disease by inoculation, are attested thus far by 211 successful inoculations.

THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.—The Pennsylvania Railroad Company has fixed the rate of fare for delegates at \$9.80 from New York to Washington and return, \$6.10 from Philadelphia to Washington and return, and \$1.65 from Baltimore to Washington and return. Limited round-trip tickets can be obtained, for these prices, at any of the offices of the road, on presentation of credentials.

Trains leave the Pennsylvania Railroad depot in Jersey City, with ferry-boat connections from the foot of Cortlandt and Desbrosses Streets, New York, and with annex-boats from Brooklyn, and from the Sound line of steamboats, on their arrival, as follows:

Leave New York	6.20 A. M.,	arrive in Washington	2.00 P. M.
" " "	8.30 A. M.,	" " "	4.45 P. M.
" " "	10.00 A. M.,	" " "	4 05 P. M.
" " "	1.00 P. M.,	" " "	8.20 P. M.
" " "	3.40 P. M.,	" " "	10.20 P. M.
" " "	7.00 P. M.,	" " "	2.55 A. M.
" " "	9.00 P. M.,	" " "	6.05 A. M.
" " "	12.00 P. M.,	" " "	8.10 A. M.

The 10 A. M. train is the Washington Limited Express, on which the fare is \$2.35 additional. The trains leaving at 1 and 7 P. M. run over the lines of the Baltimore and Ohio road after leaving Baltimore.

PROFESSOR WILLARD PARKER.—We regret to have to add to the unfavorable accounts that we have before given our readers concerning Dr. Parker's health, that on Sunday, the 13th inst., he was seized with aphasia, and since that time has constantly been losing ground, so that at the time of our going to press the fear is entertained that he can not long survive.

THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF VERMONT.—Dr. Ambrose L. Ranney, of the faculty of the New York Post-Graduate Medical School and Hospital, has gone to Burlington, to give a course of lectures on nervous diseases.

REQUESTS TO HOSPITALS.—Among the bequests in the will of the late Mr. Thomas G. Appleton, of Boston, is one of \$5,000 to the Massachusetts General Hospital, with a residuary provision for a further sum. It is stated that, by the will of the late Mr. H. B. Hurlbut, the Cleveland City Hospital is to receive \$200,000.

DUTIES ON MEDICAL SUPPLIES.—According to recent decisions by the Treasury Department, the duty on effervescent citrate of magnesium is fixed at 25 per cent., and that on carbon battery plates at 20 per cent., ad valorem.

A BILL RESTRICTING THE SALE OF DRUGS.—The State Assembly has passed a bill prohibiting the sale of drugs by any other persons than pharmacists and physicians.

THE TITLES OF MEDICAL OFFICERS OF THE ARMY.—The bill defining the titles and duties of army medical officers of the higher ranks has passed the Senate. Surgeons with the rank of Colonel are to be styled Assistant Surgeons-General, and those with the rank of Lieutenant-Colonel, Deputy Surgeons-General.

ST. FRANCIS'S HOSPITAL, it is hoped, will derive substantial help from a concert to be given in its behalf at Steinway Hall to-morrow evening.

PHYSICAL EDUCATION AT AMHERST COLLEGE.—Dr. H. H. Seelye, who recently completed his term of service on the house staff of Bellevue Hospital, has been appointed instructor in physical education at Amherst College, succeeding Dr. Hitchcock, who goes to Cornell University.

ADULTERATED TEA.—During the last thirty days 2,500 packages of adulterated tea have been seized by the United States Tea Inspector; and, in the year during which the law requiring

a strict inspection of tea has been in force, 650,000 pounds have been rejected.

THE RIBERI PRIZE.—According to the "Medical Times," of London, the seventh award, of 20,000 lire (about \$4,000), will be made for the best essay on "embryological researches, with special regard to the anatomy, physiology, and pathology of man." The essays, written or printed in the Italian, French, or Latin language, must be delivered to the Turin Academy of Medicine before the 31st of December, 1886. The MSS. will remain the property of the Academy.

MACKENZIE ON "DISEASES OF THE THROAT AND NOSE."—We regret to learn, from our London exchanges, that at a recent fire in London the entire edition of the second volume of this important work was destroyed. It will be reproduced, however, from proof-sheets in the author's possession, but its issue will necessarily be delayed for many months.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 13, 1884, to April 19, 1884:*

NEWTON, R. C., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Sill, Indian Territory, and ordered to Fort Elliott, Tex., for duty. Par. 1, S. O. 77, Headquarters Department of the Missouri, April 14, 1884.

PILCHER, JAMES E., First Lieutenant and Assistant Surgeon. Assigned to duty at Camp Poplar River, Montana. Par. 2, S. O. 37, Headquarters Department of Dakota, April 7, 1884.

CHAPIN, ALONZO R., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Douglas, Utah, and ordered to Fort Laramie, Wyoming, for duty. Par. 2, S. O. 33, Headquarters Department of the Platte, April 15, 1884.

WALES, PHILIP G., First Lieutenant and Assistant Surgeon. Ordered to report to the commanding general, Department of the Columbia, for assignment to duty. Par. 11, S. O. 84 A. G. O., April 11, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending April 19, 1884:*

WALES, P. S., Medical Director. To continue on duty as member of Ration Board.

WELLS, H. M., Surgeon. Ordered to special duty at Hot Springs, Ark.

PECK, GEORGE, Medical Director. Ordered as President of Board of Medical Officers detailed for special duty at Coaster's Island, near Newport, R. I.

GORGAS, A. C., Medical Director; **WISE, I. C.**, Surgeon. Detailed as members of Board of Medical Officers, for special duty at Coaster's Island, near Newport, R. I.

NELSON, H. C., Medical Inspector. Detached from Navy Yard, Washington, and placed on waiting orders.

McMURTRIE, D., Surgeon. Ordered to duty at Navy Yard, Washington.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, April 28th:* Medical Society of the County of New York.

Wednesday, April 30th: American Surgical Association (Washington—first day); Auburn, N. Y., City Medical Association; Medical Society of the County of Gloucester, N. J.

Thursday, May 1st: American Surgical Association (second day); Medical Societies of the Counties of Orleans, N. Y., and Ocean, N. J.; Society of Physicians of the Village of Canandaigua, N. Y.

Friday, May 2d: American Surgical Association (third day); Practitioners' Society.

Saturday, May 3d: American Surgical Association (fourth day).

Letters to the Editor.

THE AMERICAN MEDICAL ASSOCIATION.

NEW YORK, April 9, 1884.

To the Editor of the New York Medical Journal:

SIR: A most remarkable instance of manners in connection with the code of ethics has lately come to my notice, so consonant with the rules of true politeness and civility that I am constrained to lay the matter before the readers of your journal as an example to the junior members of the profession of "old-code" manners.

A well-known physician of this city was invited a few months since to discuss, at the coming meeting of the American Medical Association, the paper of an eminent physician of a neighboring city, and also to prepare an essay for the consideration of that body. This invitation was accepted, and everything was seemingly arranged, when the New York physician was notified by the chairman of the section before which the paper was to be discussed that, as he (the New Yorker) was a believer in the new code, the Committee on Arrangements of the American Medical Association could not permit him to read his paper or discuss the paper of any member.

Truly, this is a curious instance of the amenities of the "old-code" polite society; to invite a man to discuss a scientific subject, and then exclude him on the ground of a difference of views on medical etiquette, for that, after all, is what the code is—as though a man's scientific opinions could command respect only when his ideas were correct as to whom he should consult with, and how he should conduct himself with his professional brethren and the public. It almost tempts a scoffer to paraphrase Dr. Johnson's famous criticism on Lord Chesterfield's "Letters to his Son" by saying that the "old code," judging by the behavior of some of its advocates, inculcates the morals of a hypocrite and the manners of a cad.

I am, dear sir,

Your obedient servant,

F. R. STURGIS.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

Meeting of April 8, 1884.

ROBERT F. WEIR, M. D., President, in the chair.

LIGATION OF THE SAC IN STRANGULATED HERNIA.—**DR. J. C. HUTCHISON** reported two cases of strangulated hernia in which he had operated recently. Both the patients were females. One hernia was femoral and the other a direct inguinal. After dividing the stricture and returning the contents of the sac, he surrounded the sac in one case with a catgut ligature and cut it off below. In the second case he surrounded the sac with a carbonized silk ligature and then cut it off. The first patient had recovered entirely, and the second, still under observation, was doing well, her temperature at no time having been above 99° F. He had made no attempt to close the ring.

SARCOMA OF SYNOVIAL SHEATHS.—**DR. T. M. MARKOE** read a paper with this title. [See p. 467.] After reading the paper, he referred to a case in which Dr. W. T. Bull had opened the knee joint for the removal of a loose cartilage. The body was found imbedded in the edge of one of the synovial fringes, which floated into the wound as the turbid, bloody serum contained in the joint flowed out. The body was spherical or ovoidal in shape, about as large as two peas, and of a cartilaginous hardness. On

section, after hardening, the microscope showed the tumor to be composed of some small-round cells, many spindle cells, and a large number of giant cells, marking it as a *sarcoma giganteo-cellulare*, as Virchow termed these tumors, or, as they were more familiarly known, as the myeloid sarcoma of Paget. The case seemed to Dr. Markoe to have an interesting analogy to those which he had related.

Microscopical sections, prepared by Dr. Peabody, illustrating each of the tumors described, were then exhibited.

The President said that he had had the good fortune to see one of the cases which Dr. Markoe had related, and shortly afterward he had had a case which he saw at his clinic at the College of Physicians and Surgeons. A young Italian girl presented herself with an obstinate broad ganglion on the dorsum of the hand, near the wrist. The patient subsequently entered the New York Hospital and was operated upon by Dr. Peters. The tumor was found to encircle the tendons, and she had been seen lately by Dr. Abbe, who reported a recurrence of the growth. Microscopically, the neoplasm was sarcomatous.

FRACTURE OF THE NECK OF THE FEMUR.—Dr. A. C. Post said he had recently seen a case which illustrated the difficulty occasionally encountered in the diagnosis of fracture of the neck of the femur. Two weeks before, a lady about seventy seven years of age, a well-preserved and healthy person, fell one or two steps going down stairs, and immediately afterward was unable to walk, complaining of pain in the region of the hip, but did not send for him until the next evening. When he saw her she was lying on her back; the affected limb appeared very slightly everted, but, on careful measurement, he could not detect any difference in the length of the two limbs. He gave a guarded diagnosis, saying that there was possibly a fracture of the neck of the femur without separation of the fragments, and advised the patient to remain quiet. He visited her several times afterward, and found her in about the same condition, except that she gradually grew more comfortable, was able to move about in the bed without much discomfort, and, after the lapse of about ten days, everything going on favorably, he nearly abandoned the idea that fracture had occurred. He therefore allowed the patient a little more liberty, such as sitting in a chair, and allowed her to move about the room a little with the aid of assistants. He had seen her in the morning of the day of the meeting, and had found her sitting on a chair and not complaining of pain. With his assistance and the aid of an umbrella, used as a cane, she was able to walk very slowly across the room. This evening he received an urgent call to see her, with the statement that she had suddenly become very much worse and was suffering severe pain. When he reached her he found that there was more marked eversion of the foot, and that there was shortening of the limb to the extent of about seven eighths of an inch. The account given was that, while she was sitting up, some friend called, and suggested that she raise her foot and place it in another chair, which she did, and was not conscious of having injured the limb, but, when she attempted to return to the bed, she immediately began to suffer from severe pain, and Dr. Post found the condition described, which had not existed at his morning visit. He then concluded that the case was originally one of fracture of the neck of the femur without separation of the fragments, that the fragments were held together by the thick periosteum of the neck, and that probably the movement made when she raised her foot and placed it in another chair separated the fragments and allowed them to pass by each other.

He also recalled a case which occurred many years ago in the old New York Hospital. The patient was brought in after having received an injury, and he was unable to make out any shortening of the limb, although there was some eversion, with

a good deal of lameness. He gave the patient the benefit of the doubt concerning fracture, and did not make any extension or special manipulation for the purpose of diagnosis. It was near the end of his term of service, and he was followed by one of his colleagues, who, when he came on duty, was anxious to have a clear diagnosis, and therefore proceeded to make some extension and further manipulation of the limb, and subsequently there was no doubt whatever concerning the nature of the injury. Dr. Post had been in the habit of treating such cases as cases of fracture until the diagnosis became clear or until the patient got well. He thought the case reported suggested the great importance of caution in that respect, and of being contented with uncertain diagnosis rather than subject the patient to the danger of separation of the fragments, which could not afterward be brought together.

INTESTINAL OBSTRUCTION.—Dr. Post related a case of intestinal obstruction to which he had been called on the 12th of March. The patient was a previously healthy man, thirty years of age, and, when Dr. Post first saw him, the abdomen was very much distended, with a tympanitic percussion note everywhere except over the ascending colon, where there was a moderate degree of dullness without marked hardness upon palpation. The patient had had no movement of the bowels for four days. There was a moderate amount of fever, with considerable tenderness, and the pain was quite acute. He directed an enema prepared by infusing two ounces each of senna and Glauber's salt with half an ounce of cardamom seeds in a quart of boiling water, and ordered that one half of the enema be administered, to be followed by an opiate. On the following morning he found that the patient had had an imperfect evacuation following the enema, and he directed that the other half of the infusion be given, which brought away some solid matter with the liquid. Partial relief was afforded, but there was evidently a large accumulation of gas in the intestine, and he therefore directed that half an ounce of oil of turpentine and one drop of croton oil, added to a pint of flaxseed tea, be used as an injection on the following day. This gave complete relief, producing several copious evacuations, and the swelling of the abdomen subsided. The patient improved so steadily that on the 18th of March he discontinued his visits. Six days afterward the patient's wife called, saying that her husband was suffering again, and that a hard swelling had appeared the day after Dr. Post last saw him, which had continued, and that his bowels had not been freely moved. Dr. Post found that there evidently was a phlegmon forming in the region of the cæcum. A swelling existed there larger than his fist, and there was dullness on percussion. Although there was no distinct fluctuation, it was evident that the tumor was tending toward the formation of pus. He concluded to perform the exploratory operation of Dr. Willard Parker, and on the 25th of March he made an incision, separating layer after layer until he reached the immediate vicinity of the hardened mass, and, not detecting fluctuation, he made an antiseptic application (bichloride solution, eight grains to the pint) over the wound. From that time the patient began to experience relief, in the course of two or three days there was a moderate discharge of pus from the wound, the hardness subsided, and the patient was now in very good condition and in a fair way to recovery. The discharge had been carefully inspected, but no foreign body had been found. It was on the sixth day after hardness had been observed that he had made the incision, and he thought he had somewhat anticipated the actual formation of matter, which readily found its way into the artificial opening. He regarded it as safer to proceed in this manner than to take the chances of an abscess opening into the peritoneal cavity.

The President remarked that Dr. Post's case of fracture of

the femur was very interesting in several particulars, especially with reference to the difficulty of diagnosis, which in more than one instance he had himself experienced. He thought that where the patient was thin, and Bryant's line could be made out distinctly, and there was also relaxation of the fascia lata, sometimes a diagnosis could be made clear in this manner. But he had to confess that practically the rule laid down by Dr. Post must be followed, and that the case should be regarded as one of fracture until such a period had elapsed as would show unquestionably that only a contusion of the muscles had existed. Attempts to elicit crepitus should be made with great caution.

Dr. L. A. STIMSON thought the need of caution might be formulated even more strongly, and it might be said that when an elderly patient had fallen and struck upon the hip, with consequent inability to use the limb, unless absence of fracture could be positively made out, a diagnosis of fracture should be made, and the absence of fracture could only be asserted when all its minor indications were absent. As Professor Bigelow had pointed out, when no eversion could be recognized there might be diminished inversion. Another sign recently pointed out by a French surgeon, Hennequin, which Dr. Stimson had never failed to find in any case of fracture at the hip joint, since he had learned to look for it, was a lack of depressibility of Scarpa's space; that is, the fingers could be pressed into that space less deeply than normal, and the manipulation was always accompanied by pain in cases of fracture. A case had come under his observation a few days before in which there was neither eversion nor shortening, but there was inability to use the limb, and there was a fullness of Scarpa's space, and he was able, by gently flexing the limb to a right angle with the pelvis and pressing on the trochanter, to get a single click of crepitus, which made the diagnosis complete. He had been unable to get the crepitating click with the limb extended. Dr. Stimson asked the President if he had noticed the lack of depressibility in Scarpa's space.

The PRESIDENT replied that he had tried to make it out in only two cases, and it was present in each instance, but he did not rely upon it as a pathognomonic symptom. He also supplemented the case by proposing an inquiry with regard to the treatment of impaction with extreme eversion. He had seen two cases in which the eversion was so marked, in subjects under fifty years of age, that he was strongly tempted to break up the impaction, so as to get a better position for the limb, but he did not dare to do so, and the result apparently justified him in his decision, because the patients subsequently walked fairly well, much better than he had expected they ever would.

Dr. HUTCHINSON said that in his own case, an impacted fracture of the femoral neck, there was at first great doubt whether or not fracture had occurred. He was carefully measured by three competent surgeons, one of very large experience, who made out three fourths of an inch shortening, and one of the others found some shortening. The third examined in the presence of the other surgeons, and also alone several times, and was unable to make out any shortening. Dr. Hutchinson had the conviction that he had an impacted fracture, but he was not satisfied that a fracture had occurred until six or seven hours after the receipt of his injury, when symptoms developed which convinced him—namely, spasmodic contraction of the muscles about the hip when he fell asleep, which continued to occur from time to time for a week. He was disposed to regard the presence of muscular spasm about the hip joint, after severe injury of that part, as pathognomonic of fracture, but fracture here often existed when this symptom was absent. On the following day two of the three gentlemen had no doubt concerning the existence of a fracture. The fragments did not separate, although he was moved from Lake George to his home soon after the injury.

He agreed with the opinion expressed by members, that, when the diagnosis was doubtful in injuries about the hip, the case should be treated as one of fracture.

The PRESIDENT remarked, with reference to Dr. Post's case of perityphlitis, that he had recently seen a case occurring in a young person, twenty-two or twenty-three years of age, in which the specially interesting features were the presence of normal temperature and resonance on percussion over the tumor. At first there was some fever, with constipation of the bowels and severe abdominal pain; but these symptoms soon disappeared, and, after the temperature fell to normal, the tumor first showed itself. When he saw the case yesterday, in consultation, the pulse was 84, the temperature was normal, and the tumor was in the right iliac fossa, well up toward the median line, and was resonant on percussion. He had once seen a similar case under the care of the late Dr. Gurdon Buck, and the explanation which Dr. Buck gave with reference to resonance on percussion was the presence of gas in the cavity of the abscess. In the present case the diagnosis was made sure by thrusting in a hypodermic syringe, which withdrew pus, and afterward an incision was made in the line of puncture, and gas and pus were abundantly evacuated. No foreign body was found in the cavity. The discharge was exceedingly offensive, although the pus had a good color.

Dr. C. K. BRIDGON had seen two or three cases of perityphlitic abscess in which there was resonance over the tumor, and the gas which escaped was also very offensive in character. He had also seen a case of iliac abscess, as described by Dr. Buck, which was filled with gas, and for the relief of which he performed the operation devised by Dr. Buck—namely, to operate below Poupart's ligament, extending the incision down to the tendons of the psoas and iliacus muscles, opening the fascia over these tendons, and passing the finger up beneath the fascia into the iliac fossa. In this instance he passed his index-finger its entire length without getting any response. He then introduced a female catheter nearly its entire length, when there came a full puff of offensive gas, and he had the impression that he had punctured the intestine, but it was not so, for the puff was quickly followed by a large discharge of pus. The patient recovered, but eventually died of tuberculosis.

Dr. Post referred to a case of intestinal obstruction, due to impaction of feces in the rectum, occurring in a woman eighty-five years of age. She had gone repeatedly to the water-closet, and had passed small quantities of mucus. On digital examination, the rectum was found to be filled with a solid mass of fecal matter. Portions of this were removed with the handle of a spoon, and this was followed by a warm-water enema that gave complete relief.

Dr. Post also referred to a case of constipation in a lady who had given birth to a child twelve days before. She had had frequent liquid evacuations, and her attending physician had regarded the case as one of diarrhoea, for which he had prescribed opiates. When Dr. Post was called he made a digital examination, and found scybala in the rectum. The patient was relieved by an active cathartic.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Meeting of April 21, 1884.

WILLIAM DETMOLD, M. D., President, in the chair.

SCARLATINA OF THE FETUS IN UTERO AND OF THE MOTHER AT THE NINTH MONTH OF PREGNANCY.—Dr. CHARLES A. LEALE read a paper on this subject, in which he stated that scarlatina of the fetus *in utero* so seldom occurred that many physicians of extensive experience, and several writers on the diseases of children,

doubted the possibility of this disease occurring in the new-born, but, having had the sad experience of witnessing it in its malignant form in a young family, he felt it a duty to warn the profession of the danger of communicating the poison to the pregnant woman. This warning seemed specially called for, as a quotation was making the rounds of the medical journals setting forth the immunity of the puerperal woman from scarlet fever. In the light of his own experience and that of other observers, Dr. Leale said we might just as well maintain that a man who had received twenty-six bullet wounds without being killed was in a safe position. A brief summary was given of the cases of probable scarlatina in the new-born, scattered throughout medical literature, and quotations were made from different authorities on the diseases of children, expressing their doubt as to the correctness of the diagnosis of reported cases. But the accumulated testimony of a number of European and American observers strongly demonstrated the possible occurrence of scarlatina in the child at birth. In making this statement he referred to that form of scarlet fever which was contagious, and recognized as being due to a specific poison, and not to certain forms of septicæmia attended and followed by some of the symptoms and sequelæ of scarlet fever. He had attempted to gain wider information bearing upon the subject by a reference to the statistics of the Board of Health, but the figures only gave the sex and the age at which the patient was affected.

During the past twenty years Dr. Leale had seen only one case in which scarlatina had developed in the fœtus *in utero*, but he had seen three cases of undoubted puerperal scarlet fever, two in his own practice, one patient having died and the other having recovered. There were all the undoubted symptoms of the disease in a severe form—the fever, eruption, desquamation of the skin and nails, and in one case loss of hair and tedious convalescence. The third case was seen with the late Dr. Peaslee, who considered it an unmistakable case of scarlatina. The patient died soon after delivery, and the child lived but a few minutes, on account of the intensity of the throat symptoms rendering it impossible for it to breathe.

The case of scarlatina in the fœtus which had come under his observation was in a young and exceptionally healthy family. They had lived in the country, and had recently come to the city and lived in a fashionable French flat. The mother was proud to say she had never been sick, had not even had the usual diseases of childhood. She was twenty-four years of age, the father twenty-five; they had a boy of four years, and a nurse fifty years of age. A visiting relative came directly from a house where scarlet fever had prevailed in a distant city and unpacked her trunk, containing the woolen dresses, in the sleeping-room of the lady. On January 9th Dr. Leale was sent for, and found the son sick with scarlet fever. Examining the mother, who had advanced about to term, he found she also had the eruption upon the chest and abdomen, the mucous membrane of the fauces was intensely reddened, and within a few hours the entire body was covered with the eruption of a malignant form of the disease. The fœtus, from its violent motions, appeared to be in convulsions. The mother became delirious. It was considered necessary to deliver quickly in order to save either the mother or the child. The cervix was accordingly dilated, and within four hours the forceps was applied and the child extracted, without injuring mother or child. It was a large boy. The bleeding which took place with the expulsion of the placenta relieved the cerebral congestion and led to consciousness in the mother. For some hours her condition was improved, but after twenty-four hours from delivery the temperature again rose to 106.5° F., the skin became of a dark-purple color, and the symptoms in general grew worse until fifty-

six hours after delivery, when she expired. Almost immediately after death the body was beyond recognition by any of her friends. The father, alone of the entire family, escaped having the disease, he being the only one known to have had it before. All the other members of the family—viz., the son, the newly born child, and aged nurse—passed through the different stages of the disease. These three recovered.

The discussion was participated in by the PRESIDENT, Dr. J. W. S. GOULEY, Dr. W. T. Lusk, Dr. S. T. HUBBARD, and others. Dr. Lusk said there were some points referred to in the paper which perhaps might be brought out in a little stronger relief. In the first place, it was a matter of great interest that a woman exposed to scarlatina during pregnancy rarely, if ever, had the eruption appear until labor or subsequent to labor; that the period of incubation was very long, or that the poison remained undeveloped until just before or after the birth of the child. It was also interesting that the disease in the new-born was not clothed with many of its pronounced symptoms. In the woman about to be confined there might be none of the prodromes of scarlet fever, the fever and the eruption making their appearance perhaps at the same time, while in a large proportion of cases there were no throat symptoms, and, with regard to the renal symptoms, the patient might die before they had time to develop. With regard to the resemblance between a rash of septicæmia and that of scarlatina in these patients, he had decided doubts. He had seen a great many cases of septicæmia in puerperal women, but never yet the so-called scarlatinal rash unless it were really due to the poison of scarlet fever. Patients could die of scarlet fever in childhood, the disease running its entire course, to a fatal termination, without there being any inflammation of the peritoneum or any pelvic cellulitis. Sometimes puerperal peritonitis was associated with puerperal scarlatina, but in a large proportion of cases of the latter disease peritonitis did not develop. Scarlet fever had been regarded as peculiarly fatal in puerperal women, but he thought it probable that, as in children, so also in women, the intensity varied more or less in different cases and according to the form of epidemic prevailing. He had known of many cases where the disease in the puerperal woman pursued a mild course. He had supposed it would be very severe, but such had not always been the case. He had endeavored to learn whether any relation existed between the frequency of puerperal fever and that of death from scarlet fever in this city, but he had not been able to find any such relation on examining the Board of Health's statistics. About the same time Matthews Duncan made similar investigations in London with a similar result. But he thought we could not be too careful to avoid conveying poison to the puerperal woman. He was doubtful whether in the past, when he was skeptical regarding the power of the physician to convey the scarlatinal poison to the puerperal woman, he had not in one or two cases conveyed the poison in his clothing, as those patients were afterward severely ill, although no rash or soreness of the throat was present. There was no reason why such an accident might not occur, and we knew that in many epidemics scarlatina in the adult gave no symptoms which would lead us to diagnose it, but the sequelæ left no doubt regarding the nature of the previous illness.

Dr. HUBBARD said that about twenty-five years ago he had attended a lady, twenty-five years of age, in her first confinement. She had previously been perfectly well, and went through her labor in a normal manner. Three days after delivery she sickened with scarlet fever, and died on the third day following. The child sickened with the same disease about the fifth day after birth, and it also died. He was quite sure both cases were cases of scarlet fever. He was unable to trace a starting-point.

Dr. C. S. WOOD gave the history of a woman, whom he had seen in consultation on Long Island, who developed scarlatina immediately after child-birth. She rapidly grew worse, and died a few hours after labor.

Dr. LEALE, in closing the discussion, stated that, in the light of such cumulative evidence, it was our duty to acknowledge that exanthematous diseases were exceedingly dangerous to the parturient woman, and that these diseases could be communicated to the fetus *in utero* and the child be born in the midst of the eruptive period. The extreme danger to the parturient woman in contracting scarlet fever could not be too plainly stated, as nearly all those affected died. The fortunate infrequency of scarlet fever during childbed could be accounted for in two ways: The statistics of New York demonstrated that only a very small proportion of the deaths from scarlet fever occurred during the child-bearing period of women; and, again, pregnant women appeared otherwise more exempt. The statistics quoted from the report of Professor Trousseau in France clearly proved the terrible effects in country places of a severe epidemic of scarlet fever in puerperal women. The infant whose history had been reported was only saved with great difficulty, the throat symptoms at birth being so severe that the child could not breathe. Ordinary efforts to produce artificial breathing having failed, Dr. Leale, after washing out the throat, placed a porous towel over its mouth and nose, then, by completely encircling them with his own mouth, forced air into the lungs, and, by pressure on the lower ribs, forced it out again. By this means, continued for fifteen minutes, the throat was sufficiently cleared from the accumulated mucus, and the child breathed independently, and eventually recovered.

In the case of Dr. Penslee's, when both mother and child died, the infection was supposed to have originated from a family residing near by.

NEW YORK ACADEMY OF MEDICINE.

Meeting of April 17, 1884.

HORACE T. HANKS, M. D., Vice-President, in the chair.

DUPUYTREN'S FINGER-CONTRACTION.—Dr. ROBERT ABBE read a paper with this title. [See pp. 436 and 461.]

Dr. ROBERT F. WEIR said he had been impressed more than once with the nervous symptoms attending Dupuytren's contraction of the fingers, and had become pretty well convinced of its nervous origin. He believed it might be started by traumatism. He also agreed with the author regarding the value of multiple incisions, and his last suggestion, not to stretch the fingers immediately to full normal extension, he believed to be an important one.

Dr. ALFRED C. POST said he had been occupied with this subject a number of years, and he thought he was the first American surgeon to call attention to it. Of late years he had not met with many cases. The paper of the evening gave an admirable summary of the subject, and it would seem very little could be added to it. It had from the first been a matter of surprise to him that Dupuytren's contraction of the palmar fascia should have ever been mistaken for contraction of the tendons. The cases which he had seen presented nothing which resembled the contraction of tendons. He had noticed that flexion of the wrist and elbow made no difference in the appearance of the bands of contraction within the palm, whereas, if the flexor tendons had been contracted, the approximation of the origin and insertion of the muscles would have influenced the contraction. In operating, he made open sections of the contracted bands. It was not a matter of great importance whether the sections were made openly or subcutaneously, for there was entire safety with antiseptic methods, and the wounds

always healed kindly. He had had no difficulty in extending the contracted fingers, but he had met with the difficulty of which Dr. Abbe had spoken in restoring the power of flexion. For a considerable time the patients had experienced more suffering in developing the power of flexion than they had from the disease. Ultimately, however, the power of flexion had been restored. All the cases which he had seen he believed to have been of traumatic origin. They occurred for the most part in persons whose palmar integument was thin and delicate originally, and who during some unusual exercise, such as rowing, made undue pressure upon the tender parts and excited the disease. He did not know that any of the patients whom he had seen had been afflicted with gout or rheumatism. The flexion usually involved the metacarpo-phalangeal articulation; the distal phalanx was rarely involved; the second one sometimes. He had noticed in one instance that the sheath of the flexor tendon was involved, and division of the palmar fascia did not relieve flexion; it was necessary in addition to divide the sheath of the tendon. There was more inflammation following division of the sheath of the tendon than he had known to occur after division of the palmar fascia.

Dr. FRANK H. HAMILTON said he had studied this subject at an early date, and when Dupuytren gave us his observations he had tried to follow his advice, but he could not say with great satisfaction. As for the theory which Dr. Abbe had propounded, it had occupied his mind for a great many years; viz., that the malady was primarily of neurotic origin, that trophic changes occurred which were due to lesions of the nervous system, and that the atrophy of the palmar structure resulted in a permanent contracture of the fascia. The same thing took place in ligaments which for a period of time remained in a state of disuse. This explanation also made clear the reason why power returned so slowly to the flexor tendons after the hand had been straightened. There could be but little question that the disease was sometimes of traumatic origin, but, as it was usually confined to the ring and little fingers, he thought it must be ascribed in some cases to the almost permanently flexed position of these fingers in the occupation of the individual. The other fingers were more in use, their position was frequently changed, and hence no opportunity was given for atrophy from disuse.

Dr. LEWIS A. SAYRE could heartily indorse the theory of the neurotic origin of the affection. In all the cases which he had seen there had been pain even before the occurrence of contraction, and he believed that in all there had been a history of traumatism. The pain referred to might have lasted for months, consisting, perhaps, in a tingling sensation or other altered state of the sensory-nerve filaments for a long time before positive pain and contraction developed. Since he had adopted Mr. Adams's plan of treatment, cutting the contracted fascia at various points, he had obtained better results than formerly. The suggestion made by Dr. Hamilton with regard to atrophy seemed to him to be a very important one, and he had observed some of the best results take place from encouraging nutrition of the parts by massage, without division of the contracted bands. It was important after an operation to instruct the patient to manipulate the hand, and thus increase the nutrition of the atrophied tissues.

Dr. V. P. GIBNEY could bear abundant testimony to the painful and distressing neuroses from which many of Dr. Abbe's patients had suffered. He had seen a few cases in which he had made similar observations, and he regarded the paper as an important one in showing the connection between Dupuytren's contraction of the hand and an affection of the nervous system. He had observed that, in certain forms of club-foot, division of contracted bands in the fascia, after Mr. Adams's method, caused

the distortion to yield more readily, with less distress to the patient, and with better final results. He had also been struck by the fact that a good many cases of joint trouble which were called cases of rheumatism had their commencement in traumatism, and it seemed to him the basis of the permanent trouble lay in the nervous system.

Dr. AMBROSE L. RANNEY said that some years ago he made some careful dissections of the hand, to test the truth of the statement that none of the fasciuli of the palmar fascia went to the thumb. He found a few distinct cords running to the thumb in every instance. With regard to the proportion of cases of Dupuytren's contraction occurring in women, the author had given it, according to Keen, as one in twelve, but he (Dr. Ranney) thought that figures since given by the same author brought the proportion to one in five. With regard to the disease having its origin in gout and rheumatism, the theory had always seemed to him doubtful, and he remembered that Dupuytren reported a case in which the disease was congenital. He had never known gout to be congenital. He did not think the contraction need always be traced to a traumatism, for marked nervous irritation could be produced by attitude. For instance, no one could now question the neurotic origin of writer's cramp, which was produced simply by attitude. It was possible that the reason for the occurrence of the disease in the little and ring fingers more frequently than in the others might be explained in more ways than that mentioned by Dr. Hamilton. The ulnar nerve, for instance, was more frequently injured than the median, especially at the elbow, and men were more accustomed to rest their weight upon the elbow than women, which might account in part for the greater frequency of the affection in the male sex. He was not prepared to accept Dr. Abbe's statement that a sensory impression could be sufficiently localized, and be of sufficient duration, to cause a hyperplastic induration leading to such contraction. He asked if it would not be more reasonable, since the contraction usually took place slowly, to suppose that there had been an impression transmitted to the nerve centers, which gave rise to the peripheral manifestations, than to suppose that those manifestations were due to a localized compression of terminal nerve filaments. As to the occurrence of the disease in both hands, we knew there was a sympathy between homologous parts by which, if, for instance, we pinched the left ear of a rabbit, the right ear would immediately show a diminished circulation; if we plunged the right hand into cold water, the temperature of the left hand began to go down at once. Such a relation existed between corresponding parts of the lateral segments of the cord that, when members to which the filaments of one were distributed became affected, the corresponding member sympathized by reflex irritation.

Dr. R. W. AMIDON had recently seen a case of Dupuytren's contraction in which both hands became affected, but not simultaneously. The case was of interest to him because of certain other neurotic symptoms. The patient had had two attacks of temporary, but sudden and complete, loss of power in the legs. There was now only an exaggeration of the reflexes. There had also been loss of sexual appetite and power for two years past, and an atrophic condition of the left half of the tongue.

Dr. Post remarked that there was a reason why traumatism should occur upon the ulnar oftener than upon the radial side of the palm, the thenar eminence directing the obstacle to the former site.

Dr. ABBE closed the discussion, and showed some cases. He thought Dr. Post's remark concerning the reason why injury occurred upon the inner oftener than upon the outer side of the hand covered the probable explanation of the greater frequency of the deformity there. As to massage, it was to be preferred

to stretching, but some of his patients had been so treated for years without the least benefit. This had frequently been the experience of others also. He believed Dr. Ranney's explanation, that nerve bruising rather than nerve compression took place in the beginning, might be true.

NEW YORK PATHOLOGICAL SOCIETY.

Meeting of April 9, 1884.

GEORGE F. SHRADY, M. D., President, in the chair.

MYXO-FIBROMA OF THE VULVA.—Dr. H. J. GARRIGUES presented a pedunculated tumor removed from the vulva, and remarked that such tumors must be very rare, as they were not mentioned in the works of Emmet, Thomas, or Barnes. In the "Handbuch der Frauenkrankheiten," edited by Billroth, there was a figure illustrating such a case, and it was there called myo-fibroma. The exact diagnosis, however, should be myxofibroma. His specimen had been removed from a patient who was pale, dyspeptic, and suffering from an eczema of the scalp. The growth had been noticed nine years ago, but nothing had been done for it, and what induced her at last to seek relief was that the tumor began to slough and emitted an offensive odor. It was attached to the left labium majus by a pedicle of the size of the finger and of considerable length. The color was the same as that of the surrounding parts; it measured 8 cm. in length, 7 cm. in width, and 4 cm. in thickness, and had somewhat the shape of a pear. It was covered with large scales of epidermis; the surface was rather even. It was not the seat of pain, nor was it sensitive to the touch. The feel was elastic. In the pedicle rather a large artery could be felt. He applied the clamp, made a flap as in amputating the finger, cut the tumor off at the level of the clamp, tied the artery, and united the two flaps with catgut sutures. There was complete healing of the incision on a level with the surrounding tissue. He was not surprised, after making the microscopical examination, that a large amount of blood had come out of the tumor. There was no capsule; the tumor substance was immediately beneath the epidermis, which was very thick, and contained normal papillae, but no hair follicles nor glands. In the more superficial part there was considerable connective tissue with different cells interspersed. In the deeper part the cell material was very much increased while the connective tissue was decreased in amount, so that there was a fine connective tissue reticulum full of protoplasmic matter, constituting what was called myxomatous tissue. Everywhere large numbers of arteries and veins were seen.

Dr. W. M. CARPENTER remembered to have seen two cases in which the tumor was attached either directly or very close to the labia.

PEYLO-NEPHRITIS.—Dr. H. N. HEINEMAN presented specimens removed from the body of a man, forty-five years of age, who was admitted to the hospital the day before. On admission the temperature was 100.5° F. It afterward fell to 97.5°. Patient was in a moribund condition; there was sero-sanguinolent expectoration, and some blood was passed with the urine. Death took place at 1 A. M. At the autopsy, petechiae were found on the surface of the body. There was marked pulmonary congestion, with œdema. There were also some lesions in other organs, but the chief interest attached to the condition of the kidneys. The man had gonorrhœa twenty years ago, and subsequently chronic bladder trouble. The autopsy had not been fully completed, but the history pointed to stricture of the urethra, and doubtless such would be found. The walls of the bladder were thickened, and the mucous membrane was the seat of recent inflammation. One of the kidneys was enormously

increased in size, and was the seat of pyelo-nephritis. The other kidney presented in a more marked degree the ordinary lesions of chronic Bright's disease and in a less degree pyelo-nephritis. It was probable that the bladder and kidney troubles were secondary to stricture originating in gonorrhoea, and that the numerous hæmorrhages found in different organs and on the surface of the body were due to a septic influence.

CYST OF THE BROAD LIGAMENT TWISTED UPON ITS PEDICLE, SIMULATING ENLARGEMENT OF THE UTERUS.—Dr. ELIZABETH M. CUSHIER presented the specimen, which was removed from the body of a girl who died in her sixteenth year. She was admitted to the infirmary on the 26th of March. She began to menstruate at the age of fourteen. At first, menstruation was profuse. During the following two years it was irregular. Last summer there was suppression of menstruation for nine weeks. It then came on and was very profuse. The flow had diminished somewhat until four weeks previous to admission, when there was again profuse hæmorrhage, which continued until her death. Until a week previous to admission she had been attended by another physician. She was then visited by the district physician, who tamponed the vagina. On one occasion she was found with the muscles in a state of tonic contraction, and there was complete insensibility. With this exception there had been no other symptoms than those of hæmorrhage. She was said to be a nervous girl, and earlier in life had had chorea. A vaginal examination was made, and blood-clots were removed. The neck of the uterus was found to be dilated, and there was a tumor in the median line reaching half way to the umbilicus. The temperature and the pulse at that time were normal. Ergot was at first given, with the effect of apparently diminishing the hæmorrhage, but it recurred profusely. When brought to the infirmary on the 26th she was still flowing moderately. That evening there was noticed for the first time a slight elevation of the temperature, which was 100.5° F.; the pulse was 110. When Dr. Cushier saw her, on the 27th, there had been free hæmorrhage, the vagina contained dark clots, the patient was perfectly pallid, and the pulse was quite weak; the finger could be introduced as far as the internal os. The tumor in the median line gave the impression of pregnancy of about four months and a half; pressure upon it communicated an impulse to the finger on the cervix. The girl said there was a possibility of pregnancy. The tumor seemed rather soft, and gave not altogether the sensation of the pregnant uterus, but it seemed that it could not be accounted for in any other way. The hæmorrhage was quite free, and it was decided to introduce disinfected laminaria tents of small size. In the afternoon of the next day the tents were removed, but the uterus contracted so that only a sound could be introduced. The cavity still measured but three inches, as it had done before the use of the tents. It had been previously supposed that something prevented the entrance of the sound to the full depth. Examination was also made *per rectum*. Extra-uterine pregnancy was thought of, but could not be confirmed. The patient vomited incessantly, diarrhoea set in, the temperature at one time rose to 103° F., the pulse was feeble and at times irregular, and death finally ensued April 1st. The patient remained conscious to the last. At the autopsy a tumor of about the size of a child's head lay above the pubes, and was found to be a cyst of the broad ligament with a long pedicle, the latter being twisted in such a way that the tumor was held firmly over the fundus of the uterus, directly in the median line. The pedicle was probably twisted upon itself twice. The uterus was enlarged, but it was uncertain whether there had been pregnancy, or whether the enlargement was a simple hyperplastic increase. The other abdominal organs were normal except for their extreme pallor. The lungs were oedematous. There was some

mitral insufficiency, which had given rise to a murmur during life.

Dr. Cushier regarded the case as one full of interest, particularly with reference to the difficulty of diagnosis. Looking at the tumor on the table, the diagnosis would appear easy, but it had been altogether different during life. The patient was seen by several physicians of acknowledged skill, and the true condition was not recognized. The possibilities of a fibro-cyst, of a gravid uterus, of an enlarged uterus with some growth within its cavity, and of extra-uterine pregnancy, were all questions which presented themselves and could not be satisfactorily decided. Another point of interest was with regard to the cause of hæmorrhage from the uterus. In the light of the autopsy the question arose whether it was not due to interference with the return circulation by the twist of the pedicle. As to the cause of death, she thought it still remained uncertain.

Dr. GARRIGUES said there were but two ways of determining whether or not pregnancy was present. The one was by examination of the specimen, and the other was from a study of the clinical symptoms. With regard to the latter, according to his experience, the earliest signs of pregnancy were to be found in the mammae, with the exception of the somewhat doubtful gastric symptoms. He had been able to detect pregnancy as early as the sixth week by simple inspection of the mammae. It would be found that the limiting line of the areola lost its sharpness at a particular spot—namely, upward and outward. There the line became indistinct early in pregnancy, there being simply dark-colored, tongue-like projections from the circumference. At the same time there would be found some increase in the volume of the gland, but this sometimes occurred in the virgin. Another sign was the violet color of the vagina. As to hæmorrhage after abortion, it was much more likely to be found in cases in which only the ovum was thrown off, the decidua being left.

He never used tents except in extreme cases. They were very dangerous. As to the cause of death, it was probably septicæmia.

Dr. MARY PUTNAM JACOBI thought a study of the history of the case and of the post-mortem appearances would point to death from acute anæmia and heart failure rather than from septicæmia.

CARCINOMA OF THE STERNUM, CLAVICLE, AND ILIUM.—Dr. F. FERGUSON presented specimens and microscopical slides illustrating carcinoma of the bones mentioned.

ACUTE GENERAL MILIARY TUBERCULOSIS.—Dr. FERGUSON also presented a uterus the mucous membrane of which contained tubercular deposits, being the first instance in which he had seen miliary tubercles in this situation. The patient was thirty years of age, and died in a comatose state, from tubercular meningitis, five weeks after the beginning of her symptoms. The case was interesting because of the insidiousness of the invasion of the disease, and because of its rapid course. Tubercles were also found in the lungs and other portions of the body.

FIBROID INDURATION OF THE HEART.—Dr. FERGUSON also presented a number of hearts illustrating myocarditis, or fibroid induration of the walls of that organ. In some the disease was more marked than in others; in some it was associated with endocarditis, in others with pericarditis, and in still others neither of these conditions was present. In almost all the cases there was also extensive chronic diffuse nephritis, and many of the patients suffered from rheumatism, but syphilis was usually denied. It had generally been supposed that the condition was often due to syphilis. The lesion was in every instance in the left and not in the right part of the heart.

PERITONITIS IN THE INFANT.—Dr. J. LEWIS SMITH had seen

a patient only the day before its death, which occurred on the fourteenth day after birth, in which there had been nothing unusual. A week before his visit the nurse said the child had been very fretful. An increase in the temperature was afterward noted. He found evidence of peritonitis. There was great distension of the abdomen, with meteorism; the child cried when pressure was made over the abdomen. The rectal temperature was 102.4° F. During the first ten days of life the child had gained only one ounce in weight. Some matter could be squeezed from the umbilicus. The cord had separated at the seventh day. The autopsy was made by Dr. Welch. The most marked lesions were found along the course of the umbilical cord, where fibrinous pus was quite thick. The lymphatic vessels along the lower surface of the diaphragm were also filled with pus, and Dr. Welch had stated that there probably would have been an extension of the inflammatory process to the pleura had the child lived longer. The umbilical vein was filled with grayish-red, broken down, and purulent thrombi, closely adherent to the walls of the vessel. Dr. Welch explained the peritonitis by the statement that micrococci, which were present, had found their way through the umbilical vein into the peritoneal cavity, and this fact also explained the reason for there having been a greater degree of inflammation along the course of the vein. Dr. Smith said that, if this explanation of peritonitis in these little patients was accepted by pathologists, it was interesting and suggestive. Some weeks ago there had been some puerperal fever and erysipelas in the maternity wards of the institution where the child died, and for that reason the wards were closed for a time. Whether the present case was in any way connected therewith he was unable to say.

Dr. W. P. NORTHRUP had seen four cases of peritonitis in children, one of which was nine, another eleven, and a third twenty days old. He did not remember the age of the fourth. In all these cases the umbilical vein was carefully examined, and in none was thrombus found. The stamp of the cord had previously come away and left a perfectly healthy navel. In one case there was an abscess of the shoulder, which was the only other lesion which could possibly have attracted attention, and no connection between this and the peritonitis could be traced. There was no pleuritis; all the thoracic viscera were healthy. All four of the cases were, so far as could be ascertained, cases of idiopathic, acute, diffuse peritonitis. In reply to a question, he stated that the cases did not occur at a time when puerperal fever had been present in the institution; they occurred at different periods, extending over some months.

Dr. JACOBI did not think that absence of a thrombus in the umbilical vein in Dr. Northrup's cases necessarily excluded infection as a cause of the peritonitis. She could not but suppose there was infection in the case of abscess of the shoulder. The occurrence of an abscess and of peritonitis at the same time was at least very suggestive.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Meeting of March 20, 1884.

THREE CASES ILLUSTRATING SOME POINTS IN THE PATHOLOGY OF CERTAIN INJURIES OF THE SHOULDER JOINT.—Dr. C. B. NANCREE read the following paper:

A few preliminary anatomical points must be passed in review for the ready comprehension of my later remarks. The shoulder joint differs in many important points from any other articulation of the body. A moment's reflection upon the almost unlimited range of movement which it enjoys will at once suggest that the ligaments of this articulation can not be the means by which the joint surfaces are held in apposition; other-

wise anything like freedom of movement would be impossible in a ball-and-socket joint where the socket is so shallow as in this articulation. What, then, does hold, firmly apposed, the articular surfaces? It must be something always tightly stretched, yet always capable of lengthening, or rather always practically loose. Nothing but muscle could fulfill any such purpose. In truth, the muscles surrounding the joint are the most important ligaments the articulation possesses. When these are paralyzed, or in the cadaver, the head of the humerus readily falls away from the glenoid fossa. Bearing this fact in mind, you will clearly apprehend that the joint surfaces are kept pressed together solely by muscular tension. Again, the glenoid fossa, unlike the socket of any other important joint, *has no epiphysis*, which explains to a degree the fact that even in the young the head of the humerus may be so affected as to demand excision, while the glenoid process is either entirely or nearly healthy. Closely related with the scapulo-humeral joint we find a number of bursae, some of which commonly communicate with the joint, while others do not. To the former alone I shall devote my remarks. There is a large one between the acromial process and the coraco-acromial ligament upon the one hand and the shoulder capsule upon the other. Two bursae—the exact sites are unimportant for our present purposes—are situated between the subscapularis muscle and the capsule. An occasional one is placed between the infra-scapular muscle and the capsule, into which it often opens, as do the others just mentioned. Let an inflammation be set up in these sacs, and it certainly spreads to the joint itself, should communications exist, or nearly as surely by mere contiguity of tissue, if no opening between joint and bursae is present. The articulation is securely covered in by the voluminous deltoid, so that any direct injury to the fibrous or synovial tissues of the joint is almost impossible from direct force, as a blow, although a twist *may* injure it, notwithstanding the latter is more apt to tear the bursal walls. The upper epiphyses of the humerus—of which there are three—coalesce at five years, but they leave a layer of epiphyseal cartilage between head and tuberosities and shaft, which in places either coincides with the capsular attachment or is actually within it. From these anatomical facts it must be clear that direct force, as a blow, can rarely injure the joint itself, but must set up trouble either in the surrounding bursae or in the epiphyseal cartilage, or in both. Once again, the interior of the joint, the muscles moving the joint, and the skin over their attachment, are all supplied by the same nerve or nerves; so that, let a joint injury start where it may, the articulating surfaces of the shoulder joint are subjected to such an injurious degree of pressure from direct or reflex muscular contraction as is possible for no other articulation. The bearing of these anatomical facts upon prognosis and treatment need hardly be pointed out.

The first specimen I proposed showing was presented to the society some years back, and my reason for again showing it is the sharply contrasted result presented by the second specimen which I shall exhibit.

On November 27, 1878, the society had an opportunity of examining the first patient and the admirable results of the case. To those who were not present, or who have forgotten the details, I will briefly recapitulate the history of the case, with the treatment pursued.

Compound Fracture of the Anatomical Neck of the Humerus.—The patient, J. M., aged fourteen years, fell, upon the afternoon of September 23, 1878, from a tree about twenty-five feet, landing on the ground, but striking in his fall against the branches of the tree, and sustained the following injuries: The shaft of the humerus was separated from the head and greater and lesser tuberosities. The line of fracture closely followed the epiphyseal cartilage, although in several places the

diaphysis was fractured. The shaft, slightly split, was driven through the integuments over the lower part of the deltoid muscle on its anterior aspect, tearing in its course the following parts: the insertion of the deltoid was completely stripped off with the subjacent periosteum; the coraco-brachialis, teres major, and latissimus dorsi were in like manner torn off, the latter carrying with them the posterior lip of the bicipital groove. The tendon of the pectoralis major was torn off about half an inch from its insertion, and one, if not both, of the heads of the biceps was ruptured. In consequence, the head and neck of the bone, deprived of periosteum, merely hung suspended by the capsular ligament and the rotator muscles. The shell of bone connected with the head and tuberosities was fissured at various portions of its circumference, as if by the impacting action of the wedge-shaped extremity of the shaft. I enlarged the wound and removed the fragments you see, viz.: four and a quarter inches of the humerus, including its head. Seven weeks after the operation he could remove his coat, vest, and shirt without assistance. Ten weeks after the injury considerable reproduction of bone, even up to the margin of the glenoid cavity, was observed, with new attachments for the pectoral and latissimus dorsi muscles, as determined by Dr. C. T. Hunter. The actual shortening consequently amounted to only one inch and a half. He had perfect use of the forearm, could put his hand to his mouth, behind his back, and to his ear. Of course, he had lost all over-hand movements.

The course of treatment pursued, and my reasons for deciding upon it, seem worthy of detail, since such injuries are but seldom seen, and, as far as I can discover, no clear rules have been laid down for their treatment. To the members of this society who devote themselves especially to surgery, I need hardly say that no question of amputation arose in my mind; but to those in pure medical practice I would say that when the main vessels and nerves of a limb remain intact, the injury to the soft parts having been produced by the bone itself, not the fracturing force, almost any degree of shattering of the bones may be recovered from, in the young, without amputation. Two lines of treatment then offered for consideration—viz., the simple return of the bone, closure of the skin-wound, drainage, and trusting the case to nature; or the resection of the injured bone. Theoretically, the first would have seemed the better course, promising no shortening of the limb, and the retention, in a measure, of the power of the deltoid. In reality, however, the chances of union were not one in a thousand; and if not union, then necrosis with its consequent shortening; necrosis, too, meaning months or years of inflammation and supuration, matting the muscles together so that when recovery occurred—almost necessarily by an operation—the uselessness of the limb would be but slight. Resection, on the other hand, offered the complete removal of all injured portions of bone, and with them the most important factors of trouble after such an injury, thus permitting rapid healing, and the smallest possible amount of inflammatory adhesions between muscles, tendons, etc. If the bone had been simply returned, the risk to life would have been greater, owing to the prolonged supuration incident upon the separation of the necrosed bone and the deep-seated abscesses so common after compound fractures. Against it was the absolute shortening of the arm, with the prospective cessation of growth due to removal of the upper humeral epiphyses.

The actual result, I think, bears me out in the course of treatment pursued, for I hardly think that in seven weeks he would have been in so good a condition, with the wound soundly healed, if I had followed what is often, but falsely, called the "conservative" plan of treatment. I believe that true conservatism indicated exactly what I did. The amount of shortening would not have been much less had the case been left to nature and necrosis. Had this occurred, union of the severed head could not have taken place; and then the same shortening would have obtained as surely as if the epiphysis had been re-

moved. Army experience has shown that, when a portion of the upper end of the humerus is removed for injury, nothing is gained by leaving the uninjured head, since it necroses.

Although not cognizant of this fact of experience at the time of operation, anatomical knowledge, general surgical principles, and experience induced me to arrive at a conclusion by *a priori* reasoning which I have since found that extended experience had already proved.

I believe, therefore, that, theoretically and from experience, resection ought to be performed for such injuries. It is hardly necessary to say anything about the operation itself, since each case must be a rule for itself, the only point being to remove the bones with as little additional damage to the soft parts as practicable. The wound was dressed antiseptically, and, when I transferred the wards to my colleague, Dr. Packard, no supuration had occurred, and there was not the slightest inflammatory blush about the wound. He did uninterruptedly well, and the wound was soundly healed in less than seven weeks, the greater part at a much earlier date.

Sharply contrasted with this case and its results is that of the patient from whom the next specimen was removed, where the head of the humerus, luxated and partially fractured and protruding through the skin of the axilla, was *reduced* instead of being resected. Here the tension of irritated lacerated muscles, conjoined with the necessarily imperfect drainage, kept the injured bone bathed in unhealthy pus. This, with the original injury, resulted in an osteo-mylitis, which necessitated my amputating at the shoulder joint. I believe, had the head of the bone been removed, a fairly useful limb would have been the result at the end of a few weeks' treatment, while instead, after three months of illness and risk to life, amputation was the best I could do for him.

Compound Luxation (with Fracture) of the Shoulder Joint.—A man, aged thirty years, three months ago had his right arm caught by the belting and drawn over a large drum in a position of extreme abduction and probably of extension. The head of the bone was luxated, the greater tuberosity torn off, and the caput humeri thrust through the axillary integuments near the anterior axillary fold. When I first saw him at the Episcopal Hospital after the accident he was very pale, with a constant discharge of pus from an opening at the site of the old wound—i. e., near the anterior axillary fold—while the orifice of another deep-seated sinus was seen over the middle of the triceps on the outer side of the arm. A probe introduced into the anterior sinus readily touched the denuded carious head of the humerus. I attempted to excise the head of the bone, but, when I prepared to saw it, after its protrusion through the wound, I found such evidences of osteo-mylitis as to render amputation at the shoulder joint necessary. He did well and recovered, but even some months later a sinus existed, doubtless the result of necrosis of some of the fragments of periosteal bone, produced by that irritated structure. As before said, had the head of the injured bone been excised, a useful arm would have probably resulted.

The third and last case is one where a comparatively trivial injury, owing to non-treatment at first, resulted in a condition which demanded resection of the shoulder joint.

Chronic Arthritis of the Shoulder; Epiphyseal Abscess of the Humerus.—Anna M., aged seventeen years, was admitted to the female surgical ward of the Episcopal Hospital, May 14, 1883. One year ago last May she fell down stairs and struck her shoulder. She was unconscious for a short time, but was soon able to walk home. The arm did not become inflamed, and seemed to the patient well. Nine months after the fall she noticed pain in the shoulder, and an elevated papule formed near the joint, which was opened at the dispensary. This relieved the pain, but left a fistulous tract discharging healthy pus. She attended the dispensary until the 14th of last May, when she was sent into the house, Dr. Seltzer, the assistant

surgeon on duty, having touched dead bone with the probe. After admission she had pain from time to time, gradually increasing in intensity until shortly before operation. Other free openings for drainage were made by Dr. Simes and Dr. Kelley. The probe detected an apparent sequester within the humeral head. Diagnosis, epiphyseal abscess. The operation showed complete destruction of the joint, a carious and denuded humeral head with an abscess about the epiphyseal site containing a sequester. The glenoid cavity was denuded of cartilage and roughened. The portions of head and shaft, such as you see, were removed, while all the glenoid cavity was cut away with the gouge-forceps, except where the long head of the biceps was attached. Further details of the operation are unnecessary. The patient was practically well at the end of two weeks. Perfect quietude of the joint at the outset might have averted all subsequent trouble.

What was the condition here after the accident? Probably the bursa and fibrous tissues surrounding the joint were involved, and the vascular epiphyseal cartilage was congested from the jar and injury of the fall. Congestion of all these parts, instead of being relieved by complete functional rest of the articulation, with the local application of ice, leeches, etc., as appeared indicated, was kept up by the girl following her usual occupation of housework. Although in no sense markedly strumous, yet the tendency was in that direction. As the congestion increased, inflammation and suppuration were set up in the bursa, the disease spread to the articulation, gelatinous arthritis with epiphyseal abscess supervened, notwithstanding the skillful treatment of my colleagues who, *too late*, had the opportunity of treating the case.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of April 3, 1884.

THE PRESIDENT, R. A. CLEEMANN, M.D., in the chair.

DIGITAL DILATATION OF THE OS UTERI DURING LABOR.—THE PRESIDENT said that he had been taught not to dilate or stretch the os uteri with the finger, and for years this early teaching had deterred him from making any attempt to supplement the contractile powers of the uterus by assisting in the process of dilating the os. Some time since he was called to attend a primipara. The waters had been discharged the previous day, the pains had continued, but the os uteri was very small and the cervical rim hard and unyielding. He felt called upon to interfere actively, and tried to dilate the os with his finger; it softened rapidly, and in half an hour was sufficiently dilated to allow the head to pass, and delivery rapidly followed. Since that occasion he had tried the same procedure in several cases, and always with gratifying results, the labors being brought to rapid terminations where previously hours had been wasted in weary and painful waiting. The irritable condition of the os, which had been lectured upon as the consequence of such interference, he had not observed; no injury had resulted in any case. The soft finger could do no more harm, if clean, than a Barnes's or other form of dilator, and there was no danger, as with the latter, of pushing the head aside and converting a vertex into a shoulder or other faulty presentation.

Dr. W. T. TAYLOR, since he had dared to deviate from the teaching of Professor Hodge, had used his finger to assist the dilatation of the os; he did not do so if the cervix was irritable or its edge wiry.

Dr. W. H. H. GITHENS had practiced digital dilatation of the os uteri throughout his obstetrical practice, a period of eighteen years. He did not confine it to any class of cases, nor did he wait until after the membranes were ruptured. In any or all

cases he found that a "pain" was accompanied by a contraction of the circular muscular fibers of the cervix as well as of the longitudinal fibers of the body of the uterus. The contraction of the circular fibers retarded the progress of the labor. The intention of the digital distension was to paralyze these circular fibers, and thus favor the dilatation of the os. In practice this effect was rapidly produced. One or two fingers were swept around the inside of the cervix, the pulp of the finger being next the cervix, and the latter was pulled away from the head. This operation was kept up during the interval between pains; when the pain occurred the finger was withdrawn; the operation was repeated in the next interval. The membranes were not ruptured by this process. The irritable condition of the os, if it existed, was subdued. If the rim of the cervix was wiry and thin, or hard and thick, it softened and yielded; the cervix and vagina, if hot and unyielding at first, became cool and pliant; cervical tears were almost entirely avoided, and the time, pain, and exhaustion of the labor were reduced to a minimum. The process was useful in every case of labor throughout the first stage.

Dr. PHILIP M. SCHIEDT practiced digital dilatation largely. His patients said they recognized the assistance it gave them, and in subsequent labors asked him to help them. By the great shortening of the first stage of labor resulting from this method the use of the forceps was frequently avoided.

Dr. THEOPHILUS PARVIN would be sorry to see digital dilatation adopted as a rule for all cases. The fingers, used as recommended, did not act solely, possibly not chiefly, as dilators, but by evoking uterine contractions. Voluntary efforts at bearing down were not needed during the first stage; they were dangerous rather than helpful. The method might be useful in some cases after the rupture of the bag of waters, which was the natural dilating agent. There was also danger of septicæmia from germs on the fingers. He did not think the finger so good a dilator as Barnes's dilator, because unequal, partial pressure upon the os did not evoke the decided uterine contractions that uniform pressure generally did. He thought the danger of a change of presentation by the use of Barnes's dilator was very slight. He would prefer a mechanical dilator to the finger whenever dilatation was necessary, but thought something ought to be left to nature. Any sort of interference involved a possibility of danger.

Dr. ELLIOTT RICHARDSON thought there was a possible danger of rupturing the membranes. Authors cautioned us about the introduction of the finger into the uterus and the too early rupture of the membranes.

Dr. R. P. HARRIS remarked that one point had been overlooked. Why did the os not dilate easily when the head was the dilating agent? It was because it was a round surface over which the cervix did not slide easily. On the contrary, the finger was applied at successive points. One benefit of the method was that any change or danger was at once detected. The method should not be used indiscriminately, and we should not interfere unnecessarily.

THE PRESIDENT would not recommend the method in every case of labor. He had resorted to it in cases where there had been early rupture of the membranes, and the assistance of the bag of waters had been lost. In a recent case he had saved a patient hours of suffering, and the os was not bruised or injured in any way. The sight of any instrument caused the patient much anxiety, and the exhibition of Barnes's dilator, with the water, syringe, etc., caused nervous excitement. The bags sometimes burst, and thus gave the patient a terrible shock, with the added discomfort of the escaping water or air. He had always carried them, but did not like to use them.

EXANTHEMATOUS DISORDERS IN THE PUERPERAL STATE.—Dr.

PARVIN had recently had an experience of the invasion of measles and scarlet fever in the obstetric wards of the Philadelphia Hospital. In the first case in which measles occurred he did not think that the full term of pregnancy had been reached. Authorities stated that premature labor was usually caused as a result of the high temperature of the exanthematous fever. One patient had septiciæmia in addition, but recovered. The infants were not affected. In one case, soon after labor, the temperature rose to 103° F., and the patient was sent to the fever ward; at the second visit a slight rash was observed, which subsequently proved to be that of scarlatina. Desquamation was very abundant. Albuminuria was very marked on the tenth day; rheumatic pains were also felt. The patient recovered, and the child remained well. Children had been born with measles, but he did not know of such an experience with scarlet fever.

Dr. W. T. TAYLOR had reported in the "American Journal of the Medical Sciences" for 1853 a case of congenital small-pox. The mother had some febrile symptoms and pain in the back, and the child had the disease, being marked with pits. He had had a case of scarlet fever in a mother two days after labor. It proved fatal in two days; the child lived.

Dr. HARRIS remarked that in the reports of the Rotunda Maternity Hospital in Dublin there were a number of interesting reports on complications of the puerperal period by exanthematous fevers. Their mortality had been very materially influenced by these epidemics. Erysipelas was the most interesting and the most fatal of these complications. In some cases it resembled septic poisoning.

W. H. H. GITHENS, M. D., *Secretary*.

PHILADELPHIA CLINICAL SOCIETY.

Meeting of March 28, 1884.

The President. Dr. HENRY BEATES, Jr., in the chair.

SUDDEN DEATH IN DIPHTHERIA.—Dr. DANIEL LONGAKER reported the case of Mary F., aged six years, who was seen first on the afternoon of the second day of the disease. Her temperature was 104.25° F., and the general symptoms were of a decidedly adynamic type. She complained of pain and difficulty in deglutition, and a nasal tone of the voice was noticed. On inspection of the throat, congestion and swelling were evident, and a small patch of false membrane was found on the right tonsil. The local trouble continued to grow worse until the fourth day, and was associated with a diminished secretion of urine, in which albumin was found to be present. The membrane was detached on the sixth day, and by the tenth convalescence was established. On the thirteenth day she was seen for the last time. Her pulse was a little accelerated in frequency and still weak. Her appetite was good, and she was sitting up and going down stairs. Two days later, the fifteenth of the disease, after rising in the morning and feeling quite well, she suddenly fell from the chair from which she was attempting to rise and expired.

UMBILICAL HÆMORRHAGE.—Dr. JOSEPH S. GIBB read a paper with this title. In the preliminary remarks he spoke of the neglect of medical writers in omitting this important topic from their works, in spite of the oft-repeated mention of this negligence by individual observers, who, while investigating, have sought in vain in most of the standard works of the day for some account of this accident. Notable exceptions to this are the works of Simpson, Condie, and, more particularly, Dr. Bedford, of New York. The author spoke of the rarity of the accident, and proved the same by reference to the records of maternity hospitals and founding asylums, and also by the ex-

perience of the older members of the profession, and finally presented a collection of 241 cases, which represented those which had been published since 1752.

Dr. Gibb's case was that of a female child whose mother was a "bleeder." Hæmorrhage began on the third day from birth; no single bleeding point was observed. The hæmorrhage was simply a continuous oozing from the bottom of the umbilical depression. Several ligatures were applied directly to the cord, and then the ligature *en masse*, all of which failed to control the hæmorrhage. This was finally accomplished by a solution of the sub-sulphate of iron painted over the umbilicus, a pledget of cotton saturated with the same being bound fast over it. The child suffered considerably from the profuse bleeding, but soon rallied after its cessation. She was strong and healthy when last seen, one month from the date of the accident. There were no premonitory or accompanying symptoms. It was simply a spontaneous umbilical hæmorrhage.

The author would make three divisions of the subject: 1. Hæmorrhage from improper ligation of the cord. 2. Hæmorrhage the result of traumatism. 3. Spontaneous hæmorrhage. The first and second received but cursory attention, the cause and remedy being apparent. The third variety formed the true basis of the paper. He did not believe that any of the so-called premonitory symptoms—viz., colicky pains, jaundice, etc.—could be relied on as such, but thought they might occur in otherwise healthy infants or precede other affections. However, he laid stress on the fact of a hæmorrhagic diathesis existing in either parent, and believed this should make us watchful. He regarded the subjects of umbilical hæmorrhage as suffering from a general disease, and the hæmorrhage as the first symptom of this disease. This symptom might occur at any time, from a few hours to eight weeks after birth. The next most important symptom was jaundice. Both these symptoms occurred in an equal number of cases.

As regarded the ætiology, the author believed there was a direct relationship between the hæmorrhage and some constitutional condition of the infant, which condition might be either hereditary or congenital. The hæmorrhagic diathesis was given a first place in the list of causes. It was not considered absolutely necessary to invoke the aid of the hæmorrhagic diathesis in the parent to establish the existence of this condition in the offspring; in other words, it might be congenital. Attention was drawn to the hæmorrhagic symptoms in these cases, viz.: hæmorrhage from the bowels, the gums, and the funis, as proof of this peculiar condition being a strong ætiological factor. Jaundice was mentioned as forming the favorite ground of most writers on the subject as a causation of umbilical hæmorrhage, but the theories on which this was based were not regarded as substantiated by post-mortem examinations. In but few of the recorded cases were there any indications of a syphilitic or scrofulous taint. Various other minor causative influences were noted; viz., the excessive use of alkalies by pregnant women, insufficient food, etc.

In conclusion, it was recognized that, in the present crude state of our knowledge of umbilical hæmorrhage, we were obliged to admit several ætiological factors. In an analysis of the reported cases, there was found to be a strong predisposition on the part of the male to the occurrence of this accident. In 115 cases collected, where the sex is mentioned, 67 per cent. of the patients were males.

The morbid anatomy of the subject was very incomplete, being made up of statistics as to the potency or non-potency of the fetal openings and the vessels, the condition of the liver, and the character of the blood; from all of which no satisfactory conclusions could be drawn.

The prognosis was stated as exceedingly grave, the mortal-

ity being 83 per cent. in 230 cases. The fatal termination might occur at any period, from one hour to eight weeks after the commencement of the bleeding. In 94 cases, where the time of death had been stated, 47, or 50 per cent., occurred within the first forty-eight hours, twenty-five in the first, and twenty-two in the second twenty-four hours.

The success of therapeutical measures, the author believed, lay in a proper appreciation of the nature and causes of the disease, and, until these were accurately determined, umbilical hæmorrhage would continue to resist all well-meant therapeutical resources.

In the present state of our knowledge the author believed that that treatment would be the most successful which consisted of local styptics, the ligature, etc., combined with such internal hæmostatics and tonics as experience had proved to be of value in the kindred hæmorrhagic affections of adults.

Dr. CHARLES K. MILLS said he had had one very interesting case of umbilical hæmorrhage, which ended in recovery. The subject was the fourth child of perfectly healthy parents, the three other children also being healthy. There was no trouble until the third day after birth, when an oozing was found at the umbilicus, and the child vomited blood. The cord was examined and found not to be bleeding at the extremity. Subsequently, styptics were applied without result. The hæmatemesis occurred on three occasions during the following twenty-four hours of occasional hæmorrhage. The bleeding was finally controlled by transtfixion with needles, and the administration of a half-drop of aromatic sulphuric acid every two hours. The child recovered and was now perfectly healthy.

Dr. HANNAH T. CROASDALE had seen but two cases of umbilical hæmorrhage. The first was from shrinkage of the cord, which contained a great amount of gelatinous material. After the ligature was closely reapplied, the bleeding began again from the cut extremity. She then applied Péan's hæmostatic forceps, and left it in position twenty hours. In the other case the hæmorrhage was controlled by tightening the ligature.

Dr. MARY WILLITS mentioned the case of a child a week or ten days old. After considerable hæmorrhage the bleeding was checked by styptics and a compress.

The PRESIDENT said that, in a case seen by himself, the autopsy had shown gangrene of the ileum. There was also sloughing at the extremity of the cord.

Dr. GIBB said the relation of the hæmorrhagic diathesis to umbilical hæmorrhage was yet a question. There seemed, however, to be two things intimately connected with it—the hæmorrhagic diathesis and jaundice. The case reported by Dr. Mills would rather support the former theory.

Dr. ALBERT H. SMITH had seen two cases of the kind referred to. The first occurred at the end of twenty-four hours after birth, in a healthy child. On attention being called to it, the ligature was found loose; this was reapplied carefully. On the following morning the nurse again discovered hæmorrhage, and the child died before he could reach the house. This was not a case of neglect or of traumatism. The other instance occurred also in a perfectly healthy child forty-eight hours old. The cord was tied by himself, but he soon found hæmorrhage occurring freely from the tissue around the cord. A large compress of absorbent cotton was applied by means of Seabury and Johnson's plaster, and a teaspoonful of magnesia was given internally. The child was saved. In these two cases there were no hereditary tendencies to this form of trouble; no jaundice; no purpura hæmorrhagica in either the mothers or the infants themselves. We had not, so far, reached any reasonable theory of its etiology. Jaundice seemed a coincidence. Great stress had been laid on hæmophilia, but his experience did not bear it out. In

a family under his care, four out of five had died of hæmorrhage, but none had shown any tendency to umbilical hæmorrhage. In the autopsies of fatal cases no uniform or persistent conditions had been found. His cases were somewhat remarkable from the fact that recoveries were rare.

In the treatment we could hardly expect a compress to do much, yet he thought this application the best that could be made. A laxative would contribute to lessen blood pressure and act as a revulsive. He would suggest that hæmorrhage from the non-application of a ligature would rarely occur in health, if we were to judge by the fact that in Germany they seldom tied the cord. Difficulty might certainly arise from too early ligation. His practice was not to ligate until the cut extremity had ceased bleeding. It is evident that loosening the ligature would be a dangerous experiment in some of these cases.

Dr. COLLINS exhibited a bullet that had been removed from the anterior nares of a man. It had remained imbedded in the turbinated bones since 1865. An opening in the nasal septum remained, produced at the time of the injury.

G. BETTON MASSEY, M. D., *Secretary.*

Miscellany.

Therapeutical Notes.—*Mercury in the Treatment of Syphilis.*—At a recent meeting of the Philadelphia County Medical Society, in a discussion that followed the reading of a paper by Dr. John Ashhurst, Jr., Dr. John V. Shoemaker said that the use of mercury by the mouth, as recommended by the speaker, would not answer in all cases. In some the alimentary canal would not tolerate the drug, particularly in debilitated and broken-down persons. In others the mercury at times failed to make any impression, and in such instances it often passed out of the body with the secretions. He recalled a case of secondary syphilis in which he administered for several months, first the protiodide, and afterward the corrosive chloride of mercury, both in small and in large doses, without making the least impression. In this instance he afterward treated the patient by the use of the corrosive chloride of mercury hypodermically, injecting one tenth of a grain, dissolved in water, deep into the subcutaneous cellular tissue, and a cure followed within a few weeks. For the past three or four years he had followed, to a large extent, this plan of treatment with good results, and had never seen any unpleasant consequences. If the needle was in good condition, a gold one being preferable, and the operator inserted it deep into the cellular tissue, either in the superior or inferior scapular or the sacral region, abscesses would not follow. The eczematous condition of the skin that sometimes followed the inunction method of treatment, referred to by Dr. Ashhurst, could very often be avoided by using, before the inunction of the mercury, a hot-air or steam bath. At the Philadelphia Hospital for Skin Diseases he always preceded the inunction with either one or the other form of bath alluded to; it caused the ointment to be absorbed better, and thus prevented the irritation to the skin.

The Physiological and Therapeutical Action of Caffeine.—The "Gazette hebdomadaire de médecine et de chirurgie" gives the following summary of the conclusions arrived at by Dr. E. Leblond as the result of a number of experiments on man and on the lower animals: In physiological doses, caffeine is an excitant of the nerves and muscles; it decreases the frequency of the pulse, heightening the energy of the heart's action and the vascular pressure; it lowers the peripheral temperature; it has no effect on the formation or the excretion of urea. In poisonous doses, it exaggerates the excito-motor power of the medulla, paralyzes the peripheral sensory nerves, and thus acts upon the pneumogastric, diminishing its excitability; it rapidly lowers the blood-pressure by paralyzing the vaso-motors; in cold-blooded animals it

causes progressive retardation of the heart's action, finally stopping it in systole, while in warm-blooded animals it accelerates it toward the close, and arrests it in diastole; it has a tetanizing effect on the muscles; it lowers the temperature rapidly; it increases the waste of tissue. As concerns its therapeutical employment: 1. It is generally much better borne than digitalis, and, beginning with small doses, we need not fear the unpleasant effects often produced by the latter. 2. It produces regularity of the heart's action, increasing the force and reducing the frequency of its beat. 3. It provokes more or less diuresis. 4. Not only is it a substitute for digitalis, but it should always be given in grave cases, and those that threaten to prove fatal speedily, for under such circumstances it acts more surely and much more promptly than digitalis. 5. It should be given in divided doses, either in the form of a draught or hypodermically, and at the outset it should never be used in larger doses than 20 centigrammes, so as to test the patient's susceptibility, after which the dose may be increased rapidly up to between 50 and 75 centigrammes, if necessary; it is useless to go beyond a gramme and a half. 6. To sun up its therapeutical indications in diseases of the heart, it should always be employed whenever, from any cause, it becomes necessary for a patient to suspend the use of digitalis, or whenever the latter produces unpleasant results. 7. It seems to reduce the temperature in inflammations; furthermore, it is very useful as a cardiac tonic in such cases. 8. It is often of great benefit in cases of albuminuria, whether of cardiac or other origin. 9. Finally, it seems to act on the muscular structure of the intestines in cases of stranguled hernia.

TESTIMONY IN MALPRACTICE SUITS.—In a recent malpractice trial in Pennsylvania, the case being one of fracture of the lower third of the tibia and fibula, followed by necrosis of the bone, it appeared that the limb was saved, but in so shortened and deformed a state as to partially deprive the plaintiff of its use. A physician was called by the defense to prove that the treatment had been skillful, and that similar cases of fracture, followed by necrosis of the bone, generally resulted in deformity. Questions on these points were excluded, but, on appeal, this ruling was reversed and a new trial granted. The grounds for this decision are thus stated: "The limb, evidently deformed, was shown to the jury, and the course of treatment to which it had been subjected was fully described by the witnesses. The inference sought to be drawn therefrom was that careless and unskillful treatment was the cause of the deformity. Hence it was vitally important for the defendants to satisfy the jury that such was not the case; that, on the contrary, the condition of the limb as exhibited to them was the result of the severe injury the plaintiff received followed as such injuries frequently are by necroses; that the limb was in as good condition as could ordinarily be expected in such a case when properly treated by a skillful surgeon. In determining whether a disease or an injury has been treated with proper care and skill, courts and juries must depend mainly on the testimony of experts, and considerable latitude must necessarily be given in the examination of such witnesses and in propounding hypothetical questions for their opinion. The testimony proposed was competent, and the witnesses should have been permitted to answer."

THE POWERS OF BOARDS OF HEALTH.—A recent suit in a New Jersey court brought up the question whether the health board of the city of Paterson had the right to control the thickness of the walls of new buildings, under a charter which gave the power to "regulate dwelling-houses." The Court held that this statute only gave the power to regulate houses in order that they might be free from disease. The word health was broad enough, it was said, to embrace the idea of safety as well as freedom from disease, but this was not the general meaning of the word, and was not the intent of the Legislature. The powers of the health board must therefore be confined to sanitary matters.

THE MICHIGAN STATE BOARD OF HEALTH.—We are indebted to the secretary of the board, Dr. Henry B. Baker, for an account of the annual meeting, held at Lansing, April 8th, which we summarize as follows: Reports having been read of the sanitary condition of various institutions, Dr. Vaughan read a paper, prepared by Dr. C. P. Pengra, going to show the fallacy of the idea that impure water was purified by

freezing. Ordinarily, the author had found fewer infusoria and bacteria in ice than in the water from which it had been formed, but he had found them in numbers sufficient to render the ice unfit for use.

The secretary presented a summary of the registration of medical practitioners under the new law, founded on reports from seventy-six of the eighty counties in the State. The number of graduates was 2,351; of those who had attended some college, but had not graduated, 208; of those who had not attended a college, 726. The "graduates" were from all classes of medical colleges, hospitals, medical societies, etc. About seventy-five "schools" of medicine were represented, including the "cureopathic" and the "Indian." In at least one instance it was reported that the sworn statement had been signed with a "mark," the practitioner being unable to write his name. One thousand five hundred and thirty-three practitioners were registered as "regular," 490 as "homoeopathic," 398 as "allopathic," and 366 as "eclectic." Eighty-seven per cent. of the "regulars," 74 per cent. of the "homoeopaths," 61 per cent. of the "allopathists," and 47 per cent. of the "eclectics" were graduates.

It was decided to publish a list of the health officers of the State, nearly fourteen hundred in number; to issue a new edition of a document on the prevention and restriction of scarlet fever; and to publish facts in regard to several outbreaks of trichinosis in Michigan. Resolutions were passed favoring the committal of the work of preventing the introduction of infectious diseases into the country to the National Board of Health.

DR. HANKS'S SYSTEM OF BOOK-KEEPING.—We attach no great value to the many forms of combined day-book and ledger designed to facilitate the work of keeping physicians' accounts, for, so far as we are familiar with them, they all have the peculiarity of calling for addition and subtraction in a horizontal line, instead of up and down, which process is conducive to inaccuracy and vexation. There are many medical men, however, who are willing to submit to this drawback, in order that they may keep a multitude of accounts within a small compass. To those who entertain this feeling we would commend Dr. H. T. Hanks's book, sold by Messrs. J. H. Vail & Co. Its special feature is that it facilitates a *coup d'œil* of any particular account, by means of certain letters that stand out in bold relief on the page, indicating the dates on which bills were rendered and on which a settlement was made.

"MEDICAL" ALMANACS.—The perusal of one of the many so-called almanacs with which the country is annually flooded tends to disgust one, in view of the apparent ease with which commendatory certificates can be obtained from medical men and from those whose public positions ought to furnish a guarantee of sense somewhat above the average, in favor of almost any one of the multitude of worthless preparations which overrun the American market.

That a certain "plaster is more efficient than any other" is certified by one whose name is followed by Ph. D., F. C. S.; an M. D., L. R. C. S., has found the same plaster "peculiarly efficacious," as have thirteen other M. Ds., in all affections to which flesh is heir—from a common cold through the entire catalogue, including "liver complaints," "weak spine," etc. Another M. D., whose "specialty is diseases of women and children," takes "great pleasure in bearing witness to their remarkable curative power," and cites, as one of many instances, that of a lady who suffered from cold feet—"one of the symptoms of uterine congestion"—and had her feet permanently warmed by the application of a plaster to the sole of each foot.

Senators A. and B. believe them to be "the best plasters in the world," and look upon the manufacturer as a "public benefactor," while Senator C. and Assemblyman D. have had their valuable lives prolonged by the use of So-and-So's pills, which will cure "vertigo," "skin diseases" "malaria," and, when used in connection with the plaster, any ailment known except *mal à la poche*, which, strange though it may seem, considering their wonderful curative powers, their continued use is quite certain to produce.

And so we might go on, *ad nauseam*, although to that point the road is very short with the intelligent man who does not accept the trite saying, attributed to the "World's Great and Only," that the American people love to be humbugged.

Figure 3.

Original Communications.

REMARKS UPON

THE SURGICAL ANATOMY OF THE GRAVID UTERUS,

WITH PLATES.*

By WILLIAM M. POLK, M. D.,

PROFESSOR OF OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

THE object of this paper is to call attention to certain differences between the anatomy of the pregnant uterus at term and that of the non-pregnant organ.

Permit me to say here that in writing of the pelvic inlet I use the terms *brim* and *linea terminalis* as expressive of different planes in the live subject, or subject with the soft tissues in place. The latter term signifies the same here as in all works upon anatomy. The former corresponds to the anterior faces of the *psaos-magnus* muscles upon the two sides, and differs in elevation from the "line" in proportion to the thickness of the muscles.

The line of approach to the gravid uterus, above the *brim*, is across the *iliac fossæ*, consequently a knowledge of the regional anatomy of this area is essential. With the exception of some differences in the position of the round ligaments, broad ligaments, and ovarian vessels, pregnancy effects no changes in the relations of the contents of these regions, consequently, with the exception noted, the descriptions of the *fossæ* contained in any good anatomical work will answer as an introduction to what we propose writing.

The lateral pelvic wall has many objects of interest to us; but the internal iliac vessels, sacral plexus, obturator vessels and nerves, and pudic vessels, are so little affected by pregnancy that we may leave them, as we leave the contents of the *iliac fossæ*, to be studied in the standard works on anatomy. Not so, however, with the ureters, ovarian and uterine arteries, round ligaments, and broad ligaments. These undergo changes of position not fully described, and it is to these changes we beg leave to call attention.

The plates here presented, no doubt, fully explain themselves; but a few words may not be out of place. It is necessary to bear in mind that the non-pregnant uterus is below the pelvic *brim*, while the gravid uterus at term may be said to be above. This certainly is the fact in many cases of contracted pelvis, and, as such are usually the ones demanding surgical interference, our concern is chiefly with them.

The Uterine Artery in the Non-gravid Uterus (see "New York Medical Journal," vol. xxxvi, p. 566, Fig. 2, from which I reproduce the following passage).—This vessel is a branch of the anterior trunk of the internal iliac. It is given off nearly on a level with the pectineal line, just in front of the *synchondrosis*. It passes obliquely downward and forward, crossing the upper anterior portion of the great sacro-sciatic foramen, and reaching the body of the ischium above the spine. Just above the spine it begins to leave the pelvic wall, turning inward but still pur-

suing its downward course till it reaches a point midway between the spine of the ischium and the tuberosity, measured from above downward, and midway between the pelvic wall and vagina, measured from side to side; then it begins to ascend, reaching the uterus about at the utero-vaginal junction. Passing up the side of the uterus, it finally anastomoses with the ovarian. It sends numerous branches to the uterus, one of the chief being the circular artery of the cervix. This is given off at the level of the internal os, anastomosing with its fellow of the opposite side. The vessel and its branches are quite tortuous, and that portion extending from the pelvic wall to the uterus is, with the tissues in which it lies imbedded, freely movable in all directions.

In all cases having the posterior attachment of the broad ligament, the course of the artery is within its folds, running first in the outer, then in the lower, and finally ending in the inner border. Where the anterior attachment obtains, the artery for a short portion of its course is behind the ligament. This is above the spine of the ischium.

It is rather difficult to fix points as guides to the artery, but in general it may be stated that the anterior and upper portion of the great sacro-sciatic foramen contains the first part of its course, the vessel here resting on the upper fibers of the *pyriformis* muscle. A finger's breadth above the ischial spine we have the point of departure from the pelvic wall. At the center of the lateral aspect of the utero-vaginal junction we have the point of first contact with this wall, its further course being directly up the central line of the lateral aspect of the uterus. Having located the point at which it leaves the pelvic wall, and that at which it reaches the utero-vaginal junction, we may get some idea of its course between the two by remembering that it follows the line of the lower attachment or base of the broad ligament. As said before, this portion is the most tortuous, and is as freely movable as the roof of the vagina; and, as shown in the drawing, the lowest point of its downward curve is about on a line with the external os, the uterus hanging naturally in the pelvis. In this portion of its course it passes directly over the ureter, resting upon but not closely attached to it.

The Uterine Artery in the Gravid Uterus at Term (see Fig. 3).—The vessel is enlarged, though relatively less so than the ovarian artery. It is less tortuous, and its attachment to the pelvic wall is loosened and in part separated, so that but a small portion near the origin remains in contact with the wall. This is readily understood when its attachment to the uterus is remembered. The effect of elevating the organ is, first, to raise all that portion of the vessel stretching from the pelvic wall to the uterus, for this runs in a loose area of connective tissue; and next to separate a good portion of it from the wall, so that, in cases of extreme contraction of the pelvic inlet with its resulting elevation of the entire uterus, we may expect to find the vessel running from its origin directly inward and upward to reach the lateral uterine wall.

In the normal pelvis, with the gravid uterus occupying the usual position, its course, from origin to distribution, is more direct and at a much higher level than before pregnancy; but it should not be lost sight of that this level is raised and depressed along with corresponding movements of the uterus.

The level of the uterus varying even in normal cases, an exact statement of the relation of the level of the uterine

* For the explanations of the plates, see the closing paragraphs.

artery to any one of the pelvic planes is impossible, and scarcely desirable. It is, perhaps, sufficient to remember that the higher the uterus the higher is the vessel.

The relations of the vessel to the ureter are practically the same as in the non-pregnant state, resting upon and loosely attached to it, as they cross at a point about midway between the uterus and pelvic wall. Owing to the ascent of the broad ligament and consequent obliteration of its outer border, the relations between the vessel and this border are lost, but it maintains a close relation with the base-line or inferior border passing beneath it, to reach finally within its folds the lateral border of the uterus.

In approaching the lateral aspect of the lower segment of the uterus above the pelvic brim, the vessel may be distinguished as it hangs loosely in the wide-meshed area of connective tissue, filling the interval between the cervix and the lateral pelvic wall. Finding it at its junction with the uterus just above the center of the lateral aspect of the cervico-vaginal junction, we can easily trace it to its origin.

The Ovarian Artery in the Non-gravid Uterus (see "New York Medical Journal," vol. xxxvi, p. 566, Fig. 2), after descending across the posterior and inner angle of the iliac fossa, winding beneath the inner extremity of the sigmoid flexure on the left side and along the inner border of the cæcum on the right, crosses the pelvic brim at or in front of the bifurcation of the common iliac artery, sometimes as much as an inch to the front, and, accompanying the infundibulo-pelvic ligament in the upper border of the broad ligament, reaches the lower surface of the Fallopian tube. Passing close to the ovary, it follows the course of the tube to reach the cornu of the uterus, remaining thus after crossing the pelvic brim in the upper border of the broad ligament, its general direction within the pelvis being horizontal, but subject to the position of the fundus uteri.

The Ovarian Artery in the Gravid Uterus at Term (see Figs. 1, 2, and 3) is greatly enlarged. Descending across the posterior and inner angle of the iliac fossa as before, it approaches the pelvic brim at the bifurcation of the common iliac; thence it runs almost directly upward and slightly forward to reach the greatly elevated cornu of the uterus.

In this course it accompanies the infundibulo-pelvic ligament and tube, passing close to the ovary as in the non-pregnant condition, but the relation of the ovarian vessels to the tube and ovary has undergone one striking alteration. Before pregnancy the tube and ovary are so much larger than the caliber of the ovarian vessels that these vessels are overshadowed, but in pregnancy they are so much enlarged as to rather overshadow the tube and ovary.

Owing to the alterations in the broad ligament to be noted, it now runs in the posterior border of the triangular expansion of what was the upper border of that ligament.

The relations of the first portion of the rectum to this vessel are important in all operations upon the pregnant uterus, made from the direction of the left iliac fossa. They will be mentioned in a separate statement.

The Round Ligament in the Non-gravid Uterus (see "New York Medical Journal," vol. xxxvi, p. 566, Fig. 2) leaves the organ at the cornu, and, passing along the anterior face of the broad ligament just below the level of the

Fallopian tube and ovarian vessels, reaches the pelvic wall about at the linea terminalis and behind the pectineal eminence. Passing thence along the side of the external iliac vessels, it crosses first the origin of the deep epigastric vessels, then Poupart's ligament, and ascends toward the internal inguinal ring, through which it goes to reach its insertion.

In this course within the abdomen it describes three curves—one in the broad ligament, one as it crosses the brim, and one as it crosses Poupart's ligament to reach the internal ring. All this is materially changed in pregnancy.

The Round Ligament in Pregnancy (see Figs. 1 and 2) is greatly enlarged and much elongated. Leaving the elevated cornu where it has close relations with the ovarian vessels, it descends in the anterior fold of the triangular expansion of the broad ligament to reach the internal ring. No part of it dips below the pelvic brim. If the uterus be low in the pelvis, the ligament will rest upon the brim and the iliac vessels before entering the ring; but if the organ be well up, it is stretched to such an extent that its course may be that of a straight line from the cornu to the ring, no part of it coming in contact with the brim or the iliac vessels.

The result of this stretching of the ligament is to raise the peritonæum from the face of the inner, anterior angle of the iliac fossa, a matter worth remembering in operating with a view of reaching the lateral vaginal wall above the pelvic brim.

The Ureters with the Non-gravid Uterus (see "New York Medical Journal," vol. xxxvi, pp. 566 and 568, Figs. 2 and 3, from which the following description is taken):

From the kidneys to the inlet of the pelvis their course is vertical. Just above the posterior end of the crest of the ilium their line of descent is intersected at an acute angle by that of the ovarian vessels. On the right side it passes inside of the attachment of the cæcum and vermiform appendix. On the left it passes beneath the attachment of the sigmoid flexure. They strike the inlet of the pelvis near the bifurcation of the common iliac artery, just in front of it on the right, just behind it on the left. Where the broad ligament has the anterior attachment, they hug the pelvic wall till they reach the lower part of this attachment just above the spine of the ischium. In that portion of its course, on the right side it lies just behind the uterine artery, passing just in front of the internal iliac artery. On the left it crosses the internal iliac obliquely from above downward and forward.

Although behind the uterine artery, as on the right side, it is twice the distance from it till the broad ligament is reached, when the relations become much as they are on the right side. On both sides their line cuts the upper and anterior portion of the great sacro-sciatic foramen, the left farther back than the right. Starting now from the spines of the ischia, we find the left a little closer to the spine than the right; both are embraced in the folds of the base of the broad ligament. Curving inward, downward, and forward, they pass obliquely beneath the uterine artery, emerging somewhat nearer to the utero-vaginal junction than to the pelvic wall, touching the antero-lateral vaginal wall in their descent just below the level of the external os, finally ending in the base of the bladder, about an inch below and to the front of the anterior cervical lip.

In this oblique course across the pelvic floor they are from three fourths of an inch to an inch from the utero-vaginal junction.

tion, first outside, then below and in front, preserving this distance because of the downward course.

In cases having the posterior attachment of the broad ligament, the relations of the ureter after passing the ischial spines are the same as those just given; from the pelvic inlet to the spines they are somewhat different.

They are in the folds of the broad ligament the entire distance; consequently they do not hug the pelvic wall, but gradually leave it, passing about half an inch to the inner side and a little above the spines of the ischia. In this course their relations with the uterine artery are less intimate than in cases of the anterior attachment. This relation more nearly resembles that which we have in pregnancy.

In one case it was found that the left ureter lay in the outer two thirds of the left utero-sacral ligament, in this instance the ligaments having an attachment a good deal to the left of the central line of the sacrum.

The Ureters with the Gravid Uterus at Term (see Fig. 3).—The changes in the position of these tubes, consequent upon pregnancy, have been stated in a paper read before the Obstetrical Society and published in the "New York Medical Journal," May, 1882. Subsequent investigation has in no way altered the general conclusions then reached—namely, that at term the ureters are detached from the pelvic wall and raised above the level occupied prior to pregnancy. The extent of this ascent varies with the ascent of the uterus, consequently is dependent upon the capaciousness of the pelvis in no small degree. When we reflect upon the connection of the posterior and lower surfaces of the bladder with the anterior vaginal wall, as well as the intimate relation existing between that canal and the ureters, and remember that the vagina is drawn up and elongated by the traction of the ascending pregnant uterus, it is evident that there must be some ascent of the postero-inferior vesical wall and corresponding elevation of the ureters. The general upward movement of the broad ligaments and elevation of the peritonæum in the para-vesical fossæ and lateral fossæ of Douglas would serve to account for the change of position in that portion of the tubes behind the vagina, thus completing the reasons for the general alteration of position maintained. In connection with this subject it is well to bear in mind the fact, pointed out by Braun, that during parturition a considerable portion of the bladder is drawn up above the pubes, causing, no doubt, a farther ascent of these tubes, so that during labor it is fair to assume that there is a time (the termination of the first stage of labor) when what we may designate as the pelvic portion of the ureter will be raised to the level of the pelvic brim throughout most if not all of its course.

We find, however, the following to be the position of the ureters at term in a pelvis of normal dimensions:

They cross the pelvic brim at the bifurcation of the common iliac artery, the left just behind, the right just in front of that point; they wind around the inner border of the psoas-magnus muscles, across the vessels, to strike the linea terminalis about the synchondrosis. In this course they accompany the internal iliac vessels, the right ureter being in front of these vessels, the left crossing them obliquely from behind. Reaching the linea terminalis, they leave the pelvic wall, pass beneath the broad ligament, and take a

course downward, forward, and somewhat inward, passing about midway between the cervico-vaginal junction and the pelvic wall, but approach very closely the antero-lateral vaginal wall, as they turn more decidedly inward on a lower plane to strike the base of the bladder three quarters of an inch below the cervico-vaginal junction, ending finally in the bladder at a point two inches behind the spine of the pubes (the subject on the back). A line drawn from the bifurcation of the common iliac artery to the spine of the pubes corresponds in the main to the course of the ureters. From what has already been said, it is obvious that the level of the ureters at term can not be fixed absolutely, but I believe my former statement expresses as nearly as may be the average for all normal cases—viz., with the patient on the back and assuming the anterior face of the psoas muscles as the highest level of the lateral borders of the brim, the ureters, at the bifurcation of the common iliac arteries, will be found half an inch below the brim, at the extremities of the transverse diameter one inch below, and opposite the spine of the pubes two inches below the spine, or, more properly speaking, two inches behind it.*

The Broad Ligaments with the Non-gravid Uterus (see "New York Medical Journal," vol. xxxvi, p. 566, Fig. 2).—These folds, extending from the sides of the uterus to the pelvic wall, upon either side, have four borders: The inner, running from the cornua of the uterus to the level of the internal os; the lower, from the internal os to the body of the ischium, just in front of the spine of the ischium; the outer, from this spot on the ischium up the pelvic wall nearly to the brim. Sometimes the direction of this border is along the posterior half of the ischium; in other cases it runs farther back, across the upper part of the

* In an article upon "Gastro-Elytrotomy," published in the "American Journal of Obstetrics" for January, 1883, Dr. Garrigues takes exception to some of these measurements, and, in support of his exceptions, cites a specimen presented by me to the Obstetrical Society. At the time the specimen was presented, and as shown to Dr. Garrigues by me later, and as he states, it was not in condition to demonstrate the relation of the anterior extremity of the ureters to the pubic spines. All the tissues upon the outside of the pelvis had been removed, including the layers of deep and superficial fasciæ closing in the inferior strait. Consequently the vagina and rectum, and with them the posterior wall and base of the bladder, were thrown out of position, making it impossible to estimate properly the distance from the pubic spine to the vesical end of the ureter. As said, I believe two inches expresses the average for all cases, but I can understand that in this, as in the other measurements, there may be variations. The doctor's statement as to the course of the ureter in that specimen, from its crossing of the brim to the line of the transverse diameter, is in accord with my observation, but, as the specimen had been in alcohol some time, with the entire weight of the uterus resting squarely within the upper part of the pelvic canal, I was disposed to consider this position as dependent upon the abnormally applied central pressure. We found this portion of the left ureter closely hugging the inner margin of the anterior face of the psoas-magnus muscle, as far forward as the extremity of the transverse diameter. The comment upon the location of the ureter at the bifurcation of the common iliac no doubt grows out of a misinterpretation of my use of the term brim. As said, I use it to designate the level corresponding to the anterior face of the psoas magnus—a line which is above that of the iliac vessels. As regards my use of the common iliac bifurcation as a point from which to locate the ureter, I chose it in preference to the synchondrosis, as of the two it is the more easily found, and they correspond in position very nearly.

great sacro-sciatic foramen to the sacro-iliac synchondrosis. The upper border is free, extending from just below the pelvic brim to the uterine cornua. The relation of the Fallopian tubes, ovarian vessels, ovaries, uterine vessels, ureters,

FIG. 4.—A DIAGRAMMATIC SECTION OF THE BROAD LIGAMENT AND THE UTERUS JUST ABOVE THE BRIM OF THE PELVIS. *a*, the aorta; *r*, the rectum; *u*, the uterus.

and round ligaments to this border has already been mentioned in speaking of these structures. Our only concern now is with the relation of these ligaments to the uterus and pelvic cavity. In the non-pregnant condition, then, the whole of these structures is below the level of the pelvic brim, within the pelvic cavity.

The Broad Ligaments with the Gravid Uterus at Term (see Figs. 1, 2, and 4).—The ascent of the uterus is such as to lift these structures out of the cavity of the true pelvis, and their outline is so altered that they become triangular instead of quadrangular. The inner border, much elongated, still reaches from the cornua to the level of the internal os. Some lessening of the intimacy of the attachment of its layers is noticed; this is specially evident in the anterior layer as it passes over the lower segment of the uterine body.

The superior border, with all that portion of the peritonæum stretching between the ovarian vessels and round ligaments, is spread out at the sides of the uterus in the shape of an acute-angled triangle, with the base at the brim and the apex at the cornua; this conformation is the result of the tension exercised by the ligaments and vessels as the uterus ascends.

The inferior border or base-line, shortened by the expansion of the uterus, runs from the internal os to about the linea terminalis, thus occupying a level corresponding in the main to that formerly held by the superior border. From this it will appear that the outer border is virtually

obliterated. This change is the result of the traction made upon the folds of the broad ligaments as the uterus ascends. The lines of traction run from the lateral uterine wall to the inferior and outer borders, the point of greatest tension being at all times the intersection of these two. As the inferior border ascends, the adjacent peritonæum keeps pace, the result being a constant encroachment from below upward upon the outer, until finally the greater part if not the whole of it disappears to take its place upon the inner face of the triangular expansion of what was formerly the superior border. By lateral growth the uterus forces itself between the anterior and posterior layers of the broad ligaments, thus encroaching upon their horizontal measurement. Leaving the sides of the uterus in close apposition, they pass out to reach and form the inner face of the triangularly expanded superior border; there they separate, the one to pass forward around the round ligament, the other to pass backward around the ovarian vessels, both to become continuous with the peritonæum, forming the outer face of the triangular expansion described.

The effect of the tension upon the ovarian vessels and of their alteration of position is to throw the rectum somewhat back of the line along which it usually crosses the brim to unite with the sig-

FIG. 5.—After Gray, showing the inner face of the regions above and below Poupart's ligament.

moid flexure. The ascent of the lateral pouches of Douglas, and consequent ascent of the utero-sacral ligaments, serves to throw its upper portion farther back toward the central sacral line, so that at term the intestine as a whole

runs nearer this line than before pregnancy. If we seize a gravid uterus at term and make traction upward, we lift the peritoneum along the face of the psoas muscles from the sacro-iliac synchondrosis to Poupart's ligament.

If we make an incision parallel to Poupart's ligament about the level of the internal inguinal ring and push the gravid uterus well over to the opposite side, we may pass from the ring to the interior of the true pelvis without touching the peritoneum, our line of approach being beneath that of the round ligament. The effect of pregnancy is, in fact, to loosen, and even diminish, the area of peritoneal attachment in the iliac fossæ, so that separation, as has been repeatedly pointed out, is a matter of ease. Before closing I must explain the reproduction of Gray's well-known plate. It is offered in connection with the four we present in order to complete, as far as we can, the illustration of this region.

EXPLANATION OF FIGS. 1, 2, AND 3.

FIG. 1.—A front view of the uterus at term, showing the broad ligaments, the round ligaments running along the anterior margin, and the ovarian vessels running along the posterior margin.

FIG. 2.—An antero-lateral view of the gravid uterus from the left side, showing the broad ligament extended.

FIG. 3. The gravid uterus at term.—The pelvic bones in front of the pectineal eminence have been removed, and the broad and round ligaments have been cut away, showing the external and internal iliac vessels, the uterine artery and its branches, the ovarian vessels, and the obturator nerve. The rectum is turned up against the aorta. The posterior wall and base of the bladder cover the anterior cervical and vaginal walls. The ureter is shown from the bifurcation of the common iliac to its entrance into the bladder. Because of the separation of the bladder from the pelvic wall, the ureter has followed the portion attached to the vagina and cervix.

THE FUNDAMENTAL PRINCIPLES OF MECHANICO-THERAPY IN HIP DISEASE.

By MILTON JOSIAH ROBERTS, M.D.,

PROFESSOR OF ORTHOPÆDIC SURGERY AND MECHANICAL THERAPEUTICS IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; VISITING ORTHOPÆDIC SURGEON TO THE CITY HOSPITALS ON RANDALL'S ISLAND; PROFESSOR OF ORTHOPÆDIC SURGERY IN THE UNIVERSITY OF VERMONT, ETC.

(Continued from page 294.)

BEFORE making further investigations, however, with the intention of strengthening our present remedial attitude, let us first see whither our compass now points, and in the next place investigate the conditions of the craft in which we are about to voyage.

THERAPEUTIC INTERPRETATION OF CLINICAL PHENOMENA.

The therapeutic ideas, then, which our critical clinical studies have served to inspire and to indicate the desirability of simultaneously executing, may be summarized as follows:

1. For the maintenance of the comfort of the patient; the thorough artificial protection of the diseased area.

2. For the immediate nearest possible approximation to the condition of healthy local nutrition and the final perfect restoration of the functions of the diseased hip joint; the admission of articular motion within certain limits, the nature and extent of which are to be at all times placed under the surgeon's control.

3. For the continued subduction of reflex muscular spasm and the prevention of intra-articular pressure and friction; the constant exercise of firm tensile circum-femoral and circum-pelvic compression and elastic linear traction.

4. For the maintenance of the general bodily nutrition at the highest possible standard; the non-interference with the performance of the functions of healthy joints.

5. For the purposes of locomotion and the sustentation of superimposed weight; the furnishing of sufficient artificial support to practically counterbalance the loss in supporting qualities on the part of the affected member.

6. For the avoidance of unnecessary incumbrance to the patient; the maximum degree of lightness of apparatus and ease of portability.

Though our training has been such as not to beget fright when new truths are placed before us, we are not yet prepared to commit ourselves to these views, however plausible they may seem, for only a single line of evidence has been presented. One must needs be careful that his scientific beliefs be not formed too hastily or upon insufficient data. In medicine, as in other departments of knowledge, beliefs once formed, though afterward demonstrated to be erroneous, are hard to get rid of. If our therapeutic inferences be correct, they will lose nothing from an examination of other lines of evidence. Rather will they be strengthened and rendered more coherent. If they be false, the more evidence we examine the more difficult will it be to reconcile them with each other and with the freshly adduced matter. Hence our business, both for our own sake and the sake of medical science, is not now to attempt a practical test of these therapeutic ideas in the treatment of hip-diseased patients, but to adduce further facts, and note if thereby they be strengthened or weakened.

What would be thought of the commander of a transatlantic steamship, though her past history had been entirely free from accidents, who, with a cargo of precious human lives, would set sail for a foreign port without being again assured that, though the ship and her engines had seen much service, a critical examination into their condition by competent parties gave emphatic promise of continued safety? Placing ourselves in this attitude to the question in hand, we are bound under heavy penalty, before proceeding farther, to inquire into the exact condition of the parts with which we are dealing; or, in other words, into the pathology of hip disease; not for the purpose of therapeutic inspiration, but for the purpose of therapeutic confirmation.

THE PATHOLOGY OF HIP DISEASE.

In adverting briefly to the pathology of hip disease, I am happy to avail myself of the *ascertained facts* bearing upon this point which have been laboriously collated by my friend Dr. A. B. Judson, and presented to the profession in a very instructive paper read before the New York Academy

of Medicine.* Though these data were evidently collected under the impression that they supported the plan of treatment which I have designated in this paper as that of rigid support and rigid traction, they constitute, in my judgment, a most eloquent argument in confirmation of the feasibility of permitting articular motion at the hip, under the restrictions of efficient resilient support, firm tensile circumferential compression, and elastic linear traction.

The principal pathological evidence adduced in the paper referred to, and based upon actual post-mortem examinations, may be summarized in the following propositions:

1. The first morbid change in hip disease does not take place in either the femoral or acetabular articular surfaces.

2. The inflammation begins, as a rule, in the medullary tissue of the head of the femur and proceeds from within outward, involving secondarily the articular surfaces and the soft parts of the joint.

3. Abscess may develop prior to the involvement of the articular surface of either the femoral head or acetabulum.

4. Among the early changes subsequently found in the articular cartilages, and before their normal smoothness has disappeared, are their undue thinness in some places and deficient elasticity.

5. No specimens have been described in the literature of the subject which disclose erosion or ulceration on the surface of the bone or cartilage coincidently with a sound condition of the cancellated tissue.

6. The neck of the femur is almost invariably deeply ulcerated before the articular cartilage covering the head of the femur is involved by the disease.

7. The ligamentum teres is usually destroyed before serious erosion of the articular surface takes place.

8. When, as happens in the later stages of the disease, the articular cartilage begins to give way, the lesions found in it are insignificant in their extent and gravity compared with those of the underlying tissue.

9. Before ulceration or erosion of the articular surface takes place, there are clear evidences of the effects of pressure in the altered shape of the head and neck of the femur.†

Inferential Therapeutic Confirmation derived from Pathological Data.—It thus appears, from the pathological facts which we have had placed at our disposal, that, as a rule, neither the articular surfaces nor any of the soft parts of the joint (synovial membrane, capsule, etc.) are invaded by the disease until its later stages have been reached. In short, excluding the limited inflammatory focus in the head of the femur, the tissues entering into the formation of the affected articulation present no gross variations from the condition of health. Why, then, providing the comfort of the patient can be secured and his expeditious recovery insured, have we occasion, during the treatment, to deprive these healthy soft structures and articular surfaces of their function?

The changes in the shape of the articular contour of the head of the femur are readily explained on the theory that

there has been a continuance of its use for the purposes of support after its normal supporting qualities have been interfered with. This change manifestly results from the carious disintegration of its central portion, leaving, as it were, a shell of unaffected bony tissue with its incrusting cartilage, the free, smooth, rotund surface of which becomes depressed or flattened in places by undue pressure upon it. If, then, the supporting capacity of the diseased member be artificially re-enforced to the extent it has been interfered with by the inflammatory process, it is reasonable to infer that a change in the articular contour would not take place; for the superimposed pressure upon the weakened femoral head, or head and neck, could not exceed its supporting power, however slight that might be. Granting that it is possible to furnish such artificial support, and bearing in mind that our pathological studies have revealed a carious interior of the femoral head, coincidently with a healthy condition of the articular surfaces as well as of all the soft structures of the joint, is it not a rational inference that, under the conditions determined upon in our clinical examination of the patient, motion of the joint can take place without damage to the diseased area? If so, the pathology of hip disease would seem to confirm in every particular the feasibility, at least in the early stages of the majority of examples of the malady, of attempting a practical enforcement of the remedial measures deduced from a study of its bedside phenomena. Tarrying to inquire into the pathology of hip disease, have we not encountered confirmatory evidence of the value of the remedial ideas gained from previous studies? Assured, then, as we are, of the harmony between the therapeutic conceptions derived from clinical sources and the exact pathological conditions with which we are dealing, the next step in logical order is the determination of the most expedient and scientific means of executing these ideas. That we may avail ourselves of the pertinent inferences to be made in this regard from a knowledge of the normal conditions, let us go to physiology, the fountain-head, for therapeutic inspiration, and study her methods.

Just here I wish to say a word in self-defense; for, as hinted in the last sentence, I am about to invite your attention to lines of thought and observation which I am fully persuaded will be ridiculed by some as foreign to my subject, or at least having so little bearing upon it as to be possessed of no interest to the practical surgeon. To those who are familiar with the *method of discovery*, it is known that advance in the physical sciences as well as in medical science has achieved its most brilliant successes in consequence of investigations outside the narrow limitations of the concrete phenomena which inspired research. If, then, we are ever to be freed from the baffling maze of conflicting and contradictory opinions and practices which intrall our understanding of the therapeutics of hip and other allied articular diseases, it is probable that much will be gained by a study of other avenues than the clinical and the pathological.

As already pointed out, the study of physiology bids fair to yield important results. In making a casual survey of the physiological field, however, the extreme complexity of the problems to be studied and solved is at once mani-

* "Some Practical Inferences from the Pathology of Hip Disease," Vide the "New York Medical Journal," July, 1882.

† *Loc. cit.*, Figs. 1, 3, 6.

fest—and so strikingly manifest, I confess, that, were it not for my enthusiasm for the subject, I would not venture to cope with it. The questions involved are so complex that, in order to make any headway at all in their solution, it will be necessary to separate them into their individual parts, and to consider these separately; in short, to adopt the analytical method.

(To be continued.)

THE SULPHURETED-HYDROGEN HEADACHE.

By BENJAMIN LEE, M. D., Ph. D.,
PHILADELPHIA.

THE issue of this journal for November 17, 1883, contained three interesting articles on migraine, by as many writers, each of whom always commands a respectful hearing. These articles are interesting, taken together, as showing the advance which has been made of late years in arriving at certain of the essential conditions in hemicrania—for a reason, which I shall presently assign, it can not always be called sick headache—and the consequent increased precision in the use of remedies for its relief; but not less so as indicating the different standpoints from which the same conditions are regarded by different observers, and the resultant differences in therapeutics.

The first writer, Professor Hammond, regards the affection as purely vascular, differentiating, with his accustomed clearness, in the two forms, angio-spastic and angio-paralytic, in the former of which the arteries and arterioles of the head are strongly contracted, thus inducing a condition of anemia, while in the latter they are as strongly dilated, producing hyperæmia.

The author of the second article, Dr. Allan McLane Hamilton, considers the disease to be as much vascular as nervous, and recognizes also the distinction between the anæmic and the congestive forms; while the third, Dr. Alfred L. Carroll, looks upon it as a neuralgia, though he refers to the fact that vaso-motor spasm and angio-paralysis have been assigned as among its causes. Dr. Hammond has observed the two forms alternating, one attack being of the spastic and the next of the paralytic type, and even, in rare cases, both co-existing on opposite sides, while Dr. Hamilton appears to think that there may be different stages, exhibiting the two forms in the same attack. As regards therapeutics, Dr. Hammond, singularly enough, finds his two most potent remedies equally efficient in both forms—galvanism of the great sympathetic from the neck to the solar plexus, and heroic doses of bromide of sodium. With regard to the latter, he explains that the bromide not only relax vaso-motor spasms, but give tone to vessels the coats of which are relaxed. This double-edged sword which will cut short a paroxysm, of whichever kind, with equal certainty, is truly a valuable weapon, but it does seem as if the point would bear a little more elucidation.

Dr. Hamilton finds nothing so efficacious in the paroxysm as full doses of chloride of ammonium—seventy grains every hour, well diluted in Vichy water—but in the “congestive stage” gives bromide of ammonium largely. Dr.

Carroll considers that its causes are so various that no fixed rules can be laid down for its management. All three recognize the value of nitro-glycerin in the anæmic form, the first using it both during the paroxysm and in the interval, the second only in the interval. In the majority of cases Dr. Carroll has more good results from the long-continued use of cannabis indica in small doses than from any other remedy.

I confess that, to my mind, the concluding sentence of Dr. Hammond's careful paper, which seems to have been added as an after-thought, contains a truth of great significance, and one which, in these days of neuro-pathology run mad, we are too apt to overlook. The pathology of the disease in what may be called its terminal relations is admirably traced. No one can hesitate to accept it. But what as to its original cause? The nerves are, on the whole, very-well-behaved members of society. They do not get on “strikes” or raise disturbances without good cause. Like a well-ordered police force, they perform their daily round of duty quietly and unobtrusively until some danger threatens the safety of the body-politic. Then they sound the alarm, telegraph to headquarters for re-enforcements, and insist on having their complaints attended to. Any plan of neuro-therapeutics which treats them as though they were the original offenders in functional disorders is defective. It does not go back to the *fons et origo*. We can not fail to recognize in Dr. Hammond's photographic portraiture of these two allied affections a profound disturbance of a nerve-center, making itself felt in the fibrils which supply the coats of the vessels. But the nerve-center is only replying to signals of distress which it has received from other nerve-fibrils, in distant parts of the body often. It is not getting up this excitement for its own gratification. Hence he says, truly and wisely: “In both forms the stomach and bowels must be kept in good condition. Sometimes attacks of either kind are caused by *undigested food in the stomach or intestines*, and an emetic or a purgative aborts it at once.”

The old name of sick headache, connecting one form of the affection (the spastic) with failure of stomach-digestion and consequent nausea and vomiting, was not a bad one, and, while I am quite willing to admit an immense variety of causes—such as fatigue, mental tension, exposure to cold, eye-strain, uterine irritation, etc.—still this almost invariably comes in as an intervening cause, if it be not the primary one. In connection with the question of the presence of undigested food in the *primæ viæ* as a cause, either primary or secondary, I wish to propose a theory which I think I have substantiated by observation, and in regard to the plausibility of which I should be glad to have the results of the experience of other practitioners. It is this: In the angio-spastic form of migraine we have evidences of failure of *gastric* digestion in early and intense nausea and final vomiting of undigested food. In the angio-paralytic form of migraine we have evidences of failures of *intestinal* digestion, in constipation or diarrhœa with flatulence, and the discharge of sulphureted hydrogen usually in large quantities by the rectum, very rarely by the mouth.

In the former, nausea almost invariably precedes the pain, and vomiting almost invariably occurs. In the latter,

nausea occurs only as a result of long-continued, intense pain, and vomiting scarcely ever occurs. When it does, the matter vomited consists of glairy mucus only. So far from the stomach being at fault, the sufferer will often eat quite heartily, and will find a temporary relief from pain as the result of a full meal.

I take the etiology of these cases to be a poisoning of the nerve-fibrils in the mucous coat of the intestinal canal, usually of the lower bowel, by the gases of decomposition arising from the fermentation of food which the stomach has digested and passed on, but which the liver or pancreas, or both, have failed to do their full duty by, and have thus left at the mercy of the ordinary forces of nature. Sulphureted hydrogen I choose as the type of these poisonous gases, as it is very constantly present and makes its presence so unmistakably known. In one striking case which fell under my notice a gentleman suffering from a mild attack of summer diarrhoea was advised to make his breakfast principally upon soft-boiled eggs. In about two hours after the meal he began to feel symptoms of hemicrania. The pain developed rapidly, becoming very intense, until he had a profuse semi-fluid stool, accompanied by copious discharges of sulphureted hydrogen. The pain vanished as if by magic, to return in the course of an hour and increase in intensity until again relieved in the same way. This process was repeated four times, and, after the fourth fetid evacuation, the *matrices morbi* seemed to have been discharged entirely, and the pain disappeared. The analogy between the temporary relief afforded by vomiting in the angio-spastic form of the disease and that given by the evacuation of the rectum in this case can not fail to be observed.

As an additional point of distinction between the two forms, I am inclined to believe that in the angio-spastic form the pain is more apt to begin in the temporal artery or some of its branches, and in the angio-paralytic form in the occipital artery. The history of an attack of the latter is about as follows: The sufferer is first made aware of its approach by a slight sense of mental dullness and confusion of thought, with more or less fullness about the head, sometimes preceded by a feeling of exhilaration. This gradually assumes the character of a dull, diffused aching throughout the entire head, which may continue for some hours, rendering him more and more disinclined for work, especially brain-work, until finally he begins to be conscious of a concentration of the pain at the point where one of the occipital arteries emerges from the skull. If pressure be made at this point, it will be found that the artery is pulsating more strongly than its fellow and is sensitive to the touch. The pain and sense of throbbing now rapidly intensify, following the ramifications of the artery forward along the side of the head. In some cases the temporal and supra-orbital become involved, and the ball of the eye is the seat of agonizing pain, but very often these vessels escape altogether. About the time that the pain reaches its greatest intensity, discharges of sulphureted hydrogen or other fetid gas will probably begin to take place from the rectum, and will continue at intervals until the paroxysm passes off. The next evacuation will usually vary considerably from the healthy

standard, being often dark-colored, of a sticky, pasty consistence, and very fetid. Lying down greatly intensifies the occipital pain and throbbing, so that the patient will often decline to go to bed. The increased heat and general turgescence of the affected side of the head are very noticeable. The duration of the attack is about twelve hours, and it usually passes off during a sound sleep, into which the patient falls as soon as the pain begins to abate. As already said, vomiting rarely occurs, and very often there is not a trace of nausea from beginning to end.

As to the treatment, first, during the paroxysm: Emetics are, of course, of no use, as there is no undigested food in the stomach. Purgatives are too tedious in their action to be relied on to carry off the fermenting matter, and those which act the most promptly, the sulphates, are objectionable from the fact that they at once decompose and disengage sulphureted hydrogen, thus adding fuel to the flame. If the view which I have suggested be the true one, we can accomplish something by administering remedies which will check decomposition and fermentation and correct putrescence. Carbolic acid, creasote, and salicylic acid, and the salicylates, suggest themselves. I give the preference to salicylic acid, finding it much more effective than its salts. Fifteen grains, taken when the first sense of fullness and compression about the head is felt, will often ward off a paroxysm. This dose may be repeated in half an hour, and again in an hour if the first is not successful. I can not indorse Professor Hammond's suggestion of the application of cold to the nape of the neck. Our object is to stimulate the vaso-motors, and that we can accomplish more effectually by the application of heat. The hot-water bag, applied to the posterior cervical region and between the shoulders, often affords great relief. The ice-bag is indicated in the angio-spastic form, if the patient is not too chilly to be willing to bear it. Compression of the carotid on the affected side undoubtedly gives relief temporarily, but it can not be borne long enough to produce any permanent alteration in the tone of the arterial walls. Compression of the occipital by means of a handkerchief bound tightly around the head is an old domestic resource which is more effective in the long run. When the paroxysm is thoroughly established and the occipital is beating like a trip-hammer, the diseased action has become so localized in the artery that it is not possible to interrupt it. Nothing is left but to put the sufferer, if possible, into the sweet oblivion of sleep, from which we may hope he will awake free from pain.

Morphine is objectionable from its inhibitory action on the secretion of intestinal juices, and especially on the liver. The bromides are slow in their action. I prefer to make every arrangement for the patient to sleep and then give a full dose of chloral. The galvanic current as recommended by Dr. Hammond I have not tried. The faradaic, I have thought, aggravated the paroxysm. While not denying the value of digitalis or cannabis in the interval, I believe that they are inferior in value to a careful observance of hygienic and dietetic precautions and the use of massage. The value of the bile as an intestinal antiseptic is universally admitted. It should be our aim to promote its secretion in

the cases—and I believe they are frequent—in which we have reason to think it deficient. The constant use of cholagogues to stir up a liver which is constitutionally inactive is, however, to be deprecated. Abdominal massage, promoting the activity of the portal circulation and peristaltic action, with vibrations over the liver, is more potent and more permanently beneficial than blue pill, without the injurious effects of the latter. Nitro-muriatic acid, both internally and as an hepatic epithem, I have thought useful. A trial of pancreatin may also be made. But our chief care must be to proscribē those articles of diet which are prone to putrescence, and which, in decomposing, set free sulphureted hydrogen. Eggs naturally head the list. Next follow fish and shell-fish, including oysters. Then the coarse, succulent vegetables—cabbage, turnips, carrots, parsnips, etc. All meats may be permitted except veal. The use of tea and coffee can only be regulated by the experience of the patient. As a rule, however, they are injurious in the interval, but useful, taken very strong, at the outset of the attack, as a prophylactic.

The daily life should be equable. All causes which are known to check digestion and the secretion of the digestive fluids should be avoided. Among these may be noticed intense excitement, excessive exercise, protracted brain-work, over-use of the eyes at night, loss of sleep, and long exposure to intense cold.

THE PATHOLOGY AND RADICAL CURE OF HAY FEVER, OR HAY ASTHMA.*

BY JOHN O. ROE, M. D., ROCHESTER, N. Y.

FELLOW OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, MEMBER OF THE
MEDICAL SOCIETY OF THE STATE OF NEW YORK, OF THE AMERICAN MEDICAL
ASSOCIATION, ETC.

(Second Article.)

At a meeting of this society one year ago I presented for your consideration a paper† on "The Pathology and Radical Cure of Hay Fever, or Hay Asthma," an affection which has been considered the most intractable and the most distressing of the so-called minor ailments that are not immediately dangerous to life.

I pointed out that the essential subjective cause is found in the nasal passages, and is due to a hyperæsthesia, or special susceptibility of the tissues of these passages which has been induced by disease, either latent or active; that the objective cause of the irritation of these tissues during the hay-fever season is mainly (and all direct evidence goes to prove that it is solely) the pollen of various plants and grasses that float in the atmosphere during the warm months when the various plants and grasses are ripening.

Aside from the numerous experiments which have been made showing a direct cause and effect in every instance, the simple fact that by the removing of the individual entirely from the presence of pollen (and dust, which is always a violent irritant during this season, containing more or less

pollen) no symptoms of hay fever will be excited, no matter how much the tissues of the nasal passages may be diseased, or how sensitive these tissues may have become.

I also pointed out that the various symptoms that arise which appear to be more or less of a constitutional nature, producing the asthmatic and nervous symptoms, are but the reflected irritation from the nose through the sympathetic nervous system, to which may, however, be added the mechanical impediment to nasal respiration during the attack.

It is not my purpose in this paper further to discuss the ætiology and symptomatology of hay fever, but simply to add some further observations on the subject, and to present additional evidence proving the curability of the affection by removing the local cause in the nose.

There still seems to be in the minds of many a doubt as to the nature of the affection, because of the confounding of the cause and effect, or because the secondary constitutional symptoms are looked upon as the primary cause. This is but a natural mistake, which a study of the disease and of the physiological and anatomical relations of the parts involved in the affection will very readily rectify.

The recorded observations of various systemic phenomena and marked derangements in other organs arising solely from disease and irritation in the nasal passages are becoming very numerous in medical literature. That most frequently seen is asthma, which is usually a prominent symptom of an attack of hay fever.

That this asthma is unquestionably caused by a fluctuatory hyperæmia of the bronchial mucous membrane, produced by nerve irritation reflected from the nose, is shown by the frequent occurrence of asthma in conjunction with chronic affections of the nose, which disappears on the removal of the nasal disease.

Epilepsy, chorea, cerebral affections, supra-orbital neuralgia and hemicrania, laryngeal cough, spasm of the larynx, violent sneezing, are prominent among the many phenomena that nasal disease often induces.*

In an article on "Nasal Cough," Dr. J. N. Mackenzie, of Baltimore ("American Journal of the Medical Sciences," July, 1883, p. 106), has also pointed out that the seat or reflex irritability in the nose, in the production of cough, is located in the cavernous tissue at the posterior end of the inferior turbinated bones and posterior portion of the septum; that, by artificial stimulation of these parts, cough can be excited like that which is often produced by disease of these parts; but, by irritating other portions of the nasal chambers, no reflex irritability is excited, and the impression of the probe is simply that of a foreign body.

These conclusions are in entire accord with those of other observers. A number of cases have come under the observation of the writer in which they could be clearly demonstrated, not only in the production of cough, but also in the production of asthma, as cited in an article on "Nasal

* Read before the Medical Society of the State of New York at the annual meeting held at Albany, February 5, 6, and 7, 1884.

† See "Transactions" for 1883, p. 154; also "New York Medical Journal," May 12 and 19, 1883.

* Hack, of Freiburg, calls special attention to these various reflex neuroses, which are caused by nasal disease, in his brochure, "Ueber eine operative Radical-Behandlung bestimmter Formen von Migräne, Asthma, Heufieber, sowie zahlreicher verwandter Erscheinungen," August, 1883. Hack also affirms that by removing the turbinated bodies the cause of hay-fever is eliminated.

Disease a Frequent Cause of Asthma," read before the American Medical Association at Cleveland, June 6, 1883 ("Jour. of the Am. Med. Assoc.," September 15, 1883, p. 295).

It has been considered in my previous article that the vascular tissue covering the inferior turbinated bones and the lower and posterior portion of the septum is the seat of the irritation during an attack of hay fever, and that this tissue is always found hypertrophied.

This is true in the majority of cases; but an examination of a large number of hay-fever sufferers has shown that the middle and superior turbinated bones, the upper and anterior portion of the septum, or any or all portions of the nasal cavity, may also become so diseased as to be extremely sensitive to pollen irritation.

Some cases are also met with in which there is little or no hypertrophy of the turbinated tissue; but at the same time there is extreme sensitiveness of this tissue, which becomes greatly distended with blood on being excited by the slightest irritant. This is due to an increase in the size of the vessels, amounting almost to varicosity, in which the vessels have become dilated at the expense of the interstitial connective tissue. When free from irritation, the passages in these cases are commonly so free and open that, except for the appearance of the mucous membrane, disease of this tissue would be scarcely suspected.

The location of these sensitive areas can be discovered usually by the congestion and thickening of the tissues. In cases where turbinated hypertrophy or bony obstruction is the cause, it can not be mistaken or overlooked. By artificial stimulation with a probe, however, the sensitive areas can be accurately determined; for, as they are touched, marked irritation is induced—so much so that in many cases symptoms can be provoked identical and almost as severe as those attending hay fever, with lachrymation, violent sneezing, and asthma.

It has also been noticeable that, in those cases in which the septum is involved, sneezing is usually most easily provoked and most violent.

This fact would seem to indicate that, as a rule, irritation or disease of those regions of the turbinated bones covered by cavernous erectile tissue is especially provocative of asthma and cough, while the septum is the site especially provocative of sneezing.

The violent and prolonged attacks of sneezing in this affection are therefore mainly due to the pressure of the swollen turbinated tissue against the sensitive septum.

It is also to be observed that many patients suffering from chronic nasal catarrh, other than hay-fever sufferers, are often also subject to more or less prolonged attacks of violent sneezing. In these cases one or both nostrils will be found narrowed or obstructed, by a deflected septum, by a thickening of the turbinated bone, or hypertrophy of the soft parts, as the case may be, so that a small amount of irritation and turgescence of the opposite sides will bring the parts in contact. Sneezing will then be excited until free discharge of mucus takes place, the irritant is expelled, and the turgescence becomes sufficiently reduced to allow separation of the parts.

In those cases where there is constant contact between the septum and opposite wall for any considerable length of time the parts become inured, we might say, to the irritation, but any congestion of the parts and accession to the pressure will likewise provoke more or less sneezing.

It has been considered by many hay-fever sufferers that this affection is not necessarily associated with a catarrhal condition of the nasal passages during the remaining portion of the year after the disappearance of the season's attack.

This is a most decided error, for a hay-fever subject is yet to be seen who, even during the period when entirely free from the attack, has not more or less chronic rhinitis, or nasal catarrh, although often not sufficiently severe to give rise to much annoyance, particularly if the nasal passages be capacious and not markedly obstructed, whereas in small and narrow nostrils the same amount of disease would produce decided and annoying symptoms of nasal catarrh.

In many of these individuals with capacious nasal passages it is to be noticed that they become so accustomed to moderate nasal catarrh that they cease to be annoyed by it, but, when cured, marked improvement in the general health immediately follows and the taking of colds becomes correspondingly rare.

Notwithstanding the fact that in all cases the cause of hay fever arises from a catarrhal condition of the nasal passages, or chronic rhinitis, and is nearly always associated with hypertrophy of the turbinated bodies, and also the fact that it is commonly associated with more or less narrowing or occlusion of the passages (perhaps by a deflected septum, or perhaps by an enlarged or deformed turbinated bone, in addition to that caused by hypertrophy of the turbinated bodies), it must readily be seen that all patients in whose nostrils these conditions are found, and who suffer severely from nasal obstruction and nasal catarrh, do not have hay fever. Again, we often see patients in whose nostrils there is no obstruction or contact of the surfaces when free from the attack, but who have hay fever very severely. It must therefore appear that nasal obstruction can not be looked upon as the cause of hay fever, but only as *one of the conditions* predisposing to its development; but in individuals who are subject to hay fever the obstruction contributes markedly in aggravating all the conditions.

In our climate the hay-fever sufferers form but a small portion of the large number of persons who have narrowed or obstructed nasal passages, and who suffer greatly from nasal catarrh.*

This fact would seem to indicate that in hay-fever subjects this hyperæsthesia is due to a special diseased condition of the ends of the terminal nerve filaments of some or all of the branches of the fifth nerve that terminate in the mucous membrane of the nasal passages.

If such be the case, it shows that in some of these cases there must be a special proclivity for these terminal nerve

* My friend Dr. Harrison Allen, of Philadelphia, must have overlooked this fact, for, in an article on "Hay Fever and Allied Disorders" ("American Journal of the Medical Sciences," Jan., 1884, p. 156), he seems to believe that nasal obstruction alone is the direct cause of hay fever.

fibers to become diseased when so small an amount of disease of the surrounding tissues so readily affects them, and when in other cases we find no indication of these nerves being involved, however badly the surrounding tissues may be diseased.

(To be concluded.)

Clinical Reports.

NEW YORK HOSPITAL.

CLINICAL REMARKS BY ROBERT F. WEIR, M. D.

(Concluded from page 16.)

How Fractures of the Thigh and Leg are treated.

GENTLEMEN: When speaking of the use of the plaster-of-Paris bandage at my college clinic, a short time since, reference was made to its use in the treatment of fractures of the thigh and leg, and I promised to show you some time in this hospital cases illustrating the treatment of such injuries, which are not often seen at the college clinics.

I will first show you, therefore, the apparatus used in the treatment of an ordinary simple fracture of the thigh, the principle of which—extension of the limb by means of strips of adhesive plaster—was devised by Dr. Dixi Crosby, of New Hampshire, and was practically put into use in this hospital by the late Dr. Gurdon Buck, in 1852. It was about the year 1858 that this same surgeon, having got the hint from Dr. Davis, of this city, who first used it in the treatment of hip-joint disease, applied the weight and pulley as a means of extension of the limb in the treatment of fractures of the thigh, the attachment to the leg being by a long loop of sticking-plaster fastened to each side of the limb, extending up to a point just below the fracture.

The first case in which Dr. Buck made use of the apparatus was that of a child. Prior to that time a long splint was applied to the side of the leg and thigh, and at the bottom of this splint was a screw by which extension was made upon the loop of adhesive plaster. The counter-extension was made from a padded bandage passed around the perineum and buckled to the upper end of the splint. When the splint was discarded for the weight and pulley, the perineal band was fastened to the top of the bed, but, in its turn, the perineal band was done away with by the simple expedient of raising the foot of the bed, thus making the weight of the body act as the counter-extending force.

Before demonstrating to you the application of Buck's extension apparatus, as now used here, I want to show you a modification employed in the case of children, in which, instead of making traction on the limb in a line with the body, the limb is raised vertically, as you see in this little patient, and the weight passed over a pulley attached to a longitudinal bar above the bed. This method, due to Schede, of Hamburg, serves its purpose admirably, preventing the children from soiling the dressing, which they quickly do when the limb is in the horizontal position. At one time it was thought that possibly the retention of the leg constantly in the upright position might lead to congestion of the lungs, but, out of a great number of cases so treated, this accident has occurred in but a single instance. To prevent the possible rotation of the lower fragment on the upper, a double spreader (as the piece of wood is called which is inserted in the adhesive-plaster loop, just below the

foot) is employed, by which we are enabled to make extension directly in the line of the leg, not from one side, as was done when the method was first introduced; also the weight is al-

FIG. 1.

lowed to rest alongside the foot. In the case of the little patient before you, you can see that the apparatus is kept perfectly clean in this position, and it is now about three weeks since it was first applied, for a fracture of the thigh. It admits of the application of the bed-pan, and the child is in every way perfectly comfortable. It is important that the weight be sufficient to keep the nates of that side clear of the bed, and also, in the first week, that the patient's trunk be kept in a horizontal position, by a pinned towel or sheet if necessary. Children are apt to be restless, move about, and more or less displace the splint. For this reason, Dr. Hamilton, of this city, applies two splints, one to the fractured, and one to the sound leg, which gives good results, but is somewhat irksome.

Sometimes the little ones do well in a plaster-of-Paris splint, but the inherent objection to plaster of Paris is its tendency to become somewhat loosened and to chafe, especially in children. This is so marked that most surgeons have abandoned it in the treatment of fractures in this class of patients, as well as for adults.

For the purpose of illustrating the method of dressing a fracture and applying the splint, I have had this patient brought before you. In the first place, before applying the splint, you should measure the limb and compare its length with that of the sound one. The measurement should be made from the anterior superior spinous process of the ilium to the lower edge of the internal malleolus of the same limb, and compared with the same made on the sound side, the limb being placed straight with the body. Often there is a natural difference of from a quarter to half an inch in the length of the two legs. In fracture there is shortening commonly found, varying from half an inch to three inches. In this hospital measurements are carefully taken both before and after the treatment. Dr.

Buck's tables comprise the records of one hundred and forty-six cases, fifty-four of which were in children under fifteen years of age. The amount of weight employed varied from three to twenty pounds. In thirty-three of the cases no shortening at all took place; the maximum in the others was one inch, occurring in two cases. The average in the fifty-four cases was one sixth of an inch. In adults, out of ninety-two cases, there was no shortening in twelve, and the average amount was scarcely half an inch. The average weight used in these cases was fourteen pounds and a half. Remember this practical point in connection with a fractured thigh—that, when there is no more than three quarters of an inch difference in the length of the limbs, the pelvis accommodates itself thereto, and no limping takes place.

Here these fractures are usually dressed almost immediately after the patient is brought to the hospital, the history and the measurement having been first ascertained. The limb is supported by an assistant, and the foot by another assistant, and gentle traction is made, so as to keep it extended. The loop of stout sticking-plaster, but not the rubber plaster, as it often irritates, is applied and secured with a flannel bandage, which, as you know, possesses some qualities of elasticity. This bandage extends from the foot up nearly to the perinæum. I should say that some advise shaving the leg before putting the plaster on, as the patient occasionally complains of the traction on the hairs, and little ulcers have been known to result from this cause. Usually, however, unless the limb is very hairy, we do not shave it. A spreader a little wider than the distance between the malleoli is then put into the projecting loop of plaster, and to the center of this is fastened the twisted picture-wire that leads over the pulley to the weight below.

In this case the house surgeon is applying what are known as coaptation splints on each side of the limb, as well as underneath and on top. I do not think they are absolutely necessary, although they give one a feeling of greater security, on account of controlling the swelling which is apt to occur in the course of one or two days. Swelling is not usually so great in fracture of a single bone as when two are injured. The tension of the muscles acts sufficiently as splints to the bone itself. The dressing is now complete; but, when the limb is allowed to rest on a properly arranged pillow, there is always a strong tendency for the toes to roll outward. This can be guarded against by long bags of sand, but the best method is that here shown—by Volkmann's sliding rest, or traveler. This rests on two tri-

angular bars, and readily allows the patient to pull himself up in bed, by either grasping the bars above his head, or seizing the stirrup that you see hanging over each patient's bed in the wards, whenever he finds himself gravitating toward the foot. The inventive genius of Dr. Buck also extended itself to the making of this frame, which is attached to the foot of the bed, for the purpose of supporting the bed-clothes, relieving the limb of their weight. The house surgeon,

you will observe, has very carefully applied a cotton pad over the projecting toes, partly for ornament, partly for warmth. I as carefully take this off, for I prefer to have the toes uncovered and visible. It is the test of the condition of the circulation.

Look always at the toes in a fracture for several days after the injury. A German surgeon was once showing me with great satisfaction how nicely the toes were protected in similar cases in his wards, and, on removing the pad, in one of the cases gangrene was found about to take place in a part of the foot, due to disturbed circulation, which doubtless would have been detected early had the toes been left exposed. The splint is worn for about six weeks without change, unless there be some special indication. It is then removed, and the limb is measured and examined. There are two methods for determining whether union has taken place, one of which is to have the patient lift the leg by muscular effort. But this is not altogether unattended by danger, as, in case union is not perfectly firm, the fractured ends may separate. However, should such an accident occur, union takes place very rapidly, say within two or three weeks. The other method consists in gently and firmly manipulating the limb. If any doubt exists, the patient's cautiously increasing movements in the bed soon determine the question. Sometimes, while going about on crutches after removal of the splint, the patient slips and causes fracture anew. In the case of this boy whom I now show you such an accident occurred, and after this second time, which is not common, there was what is called delayed union. Let me say here a few words on this subject, as I can exhibit to you several cases of this trouble. Sometimes it is necessary to stimulate the local circulation in order to hasten union. Here is a patient in whom there was delayed union in the upper part of the thigh twelve weeks after the accident. From time to time, as the house surgeon passed through the ward, the limb was manipulated at the seat of the fracture, so as to cause irritation and an increased blood supply at the seat of the injury. After this had been done for a considerable time, until the patient cried out with pain almost with the first movement, it was discontinued, and the limb was put up in a plaster-of-Paris splint for four weeks, after which firm union was found to have taken place. Dumreicher, of Vienna, accomplished the same object by leaving a gap in the plaster-of-Paris splint at the seat of the fracture, arranging it in such a manner as to induce congestion, thus increasing the amount of blood supply and hastening union. I have tried the method in two cases with success.

Here are some other patients in whom union has been delayed. They were started walking about in a kind of frame known as "Darrach's," on which they can more or less completely support the body and take the major part of the body's weight off the bandaged limb, and at the same time sufficiently stimulate the circulation at the seat of the injury. One of the patients so going about has his fracture protected by a leather splint, and an old gentleman carries a plaster splint. The amount of mobility determines the need of a side support. Here is a man, in whom there was delayed union, who had compound fracture of the leg. He has been going about in the same way, and the limb is now doing very well.

Fractures of the Leg.—We have here, in an old lady, a Pott's fracture. The fibula is broken about two inches above the joint, and the internal malleolus is torn off. She slipped yesterday in the street, and there is but little contusion visible. The limb will now be put up in a plaster-of-Paris bandage, first lightly wrapping the leg with a flannel roller bandage, and then with a bandage into the meshes of which plaster of Paris has been rubbed, and which has been placed in a basin of water and kept there until bubbles ceased to rise. The bandage contain-

FIG. 2.

angular bars, and readily allows the patient to pull himself up in bed, by either grasping the bars above his head, or seizing the stirrup that you see hanging over each patient's bed in the wards, whenever he finds himself gravitating toward the foot. The inventive genius of Dr. Buck also extended itself to the making of this frame, which is attached to the foot of the bed, for the purpose of supporting the bed-clothes, relieving the limb of their weight. The house surgeon,

ing the plaster of Paris is made either of crinoline, of gauze, or of scrim, the latter being a coarse-meshed material used by carriage-makers to strengthen their wooden panels. From two to six layers of this bandage are applied. Plaster of Paris is a substance which rapidly becomes hardened. In half an hour it will offer considerable support; it will be completely hardened in one or two hours. The setting is hastened by putting a handful of salt into the water in which the bandages are immersed. A teaspoonful of alum will answer the same purpose. This is of service when there is much tendency to displacement of the fragments, as the extension or pressure by the assistants need not be kept up so long.

I here demonstrate to you the method of putting up a broken leg in a fracture-box. The box is open at the top and at the end next the body, and has sides and a foot-piece folding outward. It is padded with tow, jute, or bran, the padding being made thicker at the lower part of the leg, but it should not extend below the malleoli, for all pressure on the heel is to be avoided. When the limb is in place, the sides are raised up, the bran or other padding is packed so as to hold the limb laterally, the foot is secured to the foot-piece, and a bandage is passed over a large pad of blanket at the upper portion of the box, to prevent the possibility of the patient's moving the leg. To help keep the heel from touching the splint, a support made of sticking-plaster, preferably in this case of the rubber plaster, can be nicely adapted to the heel in the manner which I show you: a

FIG. 3.

FIG. 4.

circular piece is cut out near the edge, of the size of the heel, the strip at the edge is cut through into the circular opening, and the flaps are overlapped so as to make a cup-shaped cavity to cover the heel accurately and also to adhere to the sole. The loose end, which is reversed, is stuck to the outside of the foot-piece, and over all a short bandage is carried. This support should supplement that afforded by the cushion under the tendo Achillis. You will notice that the same contrivance is employed in Volkmann's traveler in the treatment of fractured thigh. It is the house surgeon's duty, in all fractures of the lower extremity, to see daily that the heel is not resting on the bed of the splint, for bed-sores readily occur here from neglect of this precaution.

A lighter splint than the plaster of Paris is made from what is called water-glass, consisting of a soluble silicate of sodium, which is applied on a muslin or crinoline bandage by means of a brush. It dries more slowly than plaster of Paris, but it is lighter, and may be employed for sprains, or at the end of the second or third week in cases of fractured leg. The plaster-of-Paris splint is removed with some difficulty. It may be done with a pair of shears made specially for the purpose, or with a knife. When the knife is used, the leg may be protected by passing a flexible ivory paper-cutter down between the dressing

and the skin. The bandage is somewhat easier to cut when moistened with water, and some surgeons lay a strip of cloth soaked in weak nitric acid along the line of incision over-night, to soften it. The water-glass splint is more easily cut through, or the patient can speedily soak it so that the bandage can readily be unwound.

When a fracture of the leg occurs near the knee, as in the case of this boy, the splint, you will see, has to extend above the knee, rendering the joint stiff, in order that the upper fragments of the fractured tibia and fibula may be supported. When the fracture is at the lower part of the limb, the splint need not extend above the joint. The rule with us is to take off the first splint at the end of a week or ten days, and then apply one more snugly than at first, and the latter is not removed until six weeks after the reception of the injury.

When a compound fracture has advanced so far as to bear a plaster splint, or when, as in this case, the patient has a sore near the seat of the fracture, from contusion, a modification of the splint is required, in order to give exit to the discharges, and to enable us to dress the wound. An opening, or window, has to be cut in the plaster-of-Paris bandage after it is dry. This is not always an easy matter. To do it safely, some cotton is put over the ulcer, over that a square of rubber adhesive plaster larger than the opening is laid face upward, and then the plaster-of-Paris bandage; when the latter is hard, a piece is cut out. The cotton protects the parts better than anything else, and the adhesive plaster is cut across and turned over the edges of the opening, and helps to render them proof against soakage. To help prevent leakage of the discharges under the dressing farther down the leg, the space between the latter and the splint may be padded with rubber or cotton cloth, and this edge and the adjacent splint may be rendered non-absorbent by being painted with shellac dissolved in alcohol.

While I can safely tell you that simple fractures of the leg may be put up immediately after the injury, and while, as you see, that practice is followed in the hospital, where they can be watched carefully, and damage from undue swelling guarded against, yet the old injunction holds good for these latter injuries in the case of young practitioners—it is better for them to use the fracture-box or some other loose splint until the swelling begins to subside, and then resort to the plaster splint.

Book Notices.

BOOKS AND PAMPHLETS RECEIVED.

Medical Annals of Baltimore, from 1608 to 1880, including Events, Men, and Literature. To which is added a Subject-Index and Record of Public Services. By John R. Quinan, M. D., etc. Baltimore, 1884. Pp. 274.

The Pathology, Diagnosis, and Treatment of Diseases of the Rectum and Anus. By Charles B. Kelsey, M. D., Surgeon to St. Paul's Infirmary for Diseases of the Rectum, etc. With two chromo-lithographs and nearly one hundred illustrations. New York: William Wood & Co., 1884. Pp. xiii+416.

Shakespeare as a Physician. Comprising every Word which in any way relates to Medicine, Surgery, or Obstetrics, found in the Complete Works of that Writer, with Criticisms and Comparison of the same with the Medical Thoughts of to-day. By J. Portman Chesney, M. D., Ex-secretary, Medical Society of the State of Missouri, etc. Chicago, St. Louis, and Atlanta: J. H. Chambers & Co., 1884. Pp. 226.

National Board of Health. Remarks before the Committee

on Public Health of the House of Representatives in Support of House Bill 2,785, 48th Congress, 1st Session, for the Protection of the Public Health, and in Refutation of Charges made against the Board by the Supervising Surgeon-General of the Marine-Hospital Service. Washington, 1884.

National Board of Health. Closing Argument submitted to the Committee on Public Health of the House of Representatives, 48th Congress, 1st Session, in Support of House Bill 2,785, for the Protection of the Public Health, and in Refutation of the Charges made against the Board by the Supervising Surgeon-General of the Marine-Hospital Service. Washington, 1884.

National Board of Health. Remarks before the Committee on Public Health of the House of Representatives in Support of House Bill 2,785, 48th Congress, 1st Session, for the Protection of the Public Health. By Dr. James L. Cabell. Washington, 1884.

Post-nasal Catarrh and Diseases of the Nose causing Deafness. By Edward Woakes, M. D., Senior Aural Surgeon, and Lecturer on Diseases of the Ear, London Hospital, etc. Illustrated with wood engravings. Philadelphia: P. Blakiston, Son & Co., 1884. Pp. 224. [Price, \$1.50.]

New York State Medical Association. Founded February, 1884.

First, Second, and Third Annual Reports of the Secretary of the State Board of Health of West Virginia, for the Years ending December 31, 1881, 1882, 1883. Wheeling, 1883.

Sarcoma Cístico del Testículo Derecho. Por José Armangué y Carreras-Solá. Trabajo del Laboratorio del Dr. Carreras-Aragó. Barcelona: Evaristo Ullastres, 1884. Pp. 35.

Introduzione allo Studio dei Bacteri. Pel Dott. C. Bergonzini. [Reprint from the "Spallanzani."]

A Review of the Operation of Gastrotomy for Myo-fibromata of the Uterus, with Complete Statistical Tables. By Horatio R. Bigelow, M. D., Washington, D. C. [Reprint from the "American Journal of Obstetrics."]

A Contribution to the Morbid Anatomy of Pons Lesions, including a Description of a Descending Degeneration of the Stratum Intermedium. By Edward C. Spitzka, M. D., Professor of Neuro-Anatomy and Pathology at the New York Post-Graduate Medical School, etc. [Reprint from the "American Journal of Neurology and Psychiatry."]

On the Discovery of the Periodic Law, and on Relations among Atomic Weights. By John A. R. Newlands, F. I. C., F. C. S., Member of the Society of Public Analysts, etc. London: E. & F. N. Spon, 1884. Pp. viii-39.

London Water Supply. Report, etc., No. xxxvii.

Correspondence.

LETTER FROM EDINBURGH.

The Fictical of the Tercentenary of the University; its Medical Aspects.—The Delegates, from Learned Bodies in Foreign Countries.—The Honorary Degree of Doctor of Laws.—The Banquet; Professor Virchow's Speech.

EDINBURGH, April 18, 1884.

THE taunt has been heard now and then that the University of Edinburgh was of little more than local importance—that its actual contributions to the advance of knowledge were comparatively meager—in short, that it was a "slow coach." If some of us Scotsmen have occasionally felt the smart of these uncomplimentary reflections, we have been abundantly compen-

sated by the events which the tercentenary has called forth. Surely, the world of science, literature, and art would not have sent such delegations—coming from every state in Europe except Spain, Greece, and Turkey, as well as from the United States and Canada—as have been seen in Edinburgh this week, if the occasion had been generally esteemed to be one of local importance only.

The festivities may be said to have culminated yesterday. For a number of days the city had worn a holiday aspect, but yesterday additional bunting, with the arrival of great numbers of curious country people, made it still gayer. Everybody seemed to feel the greatness of the occasion. In the morning, a multitude of people having gathered in Synod Hall, the delegates were received and the honorary degrees were conferred. Among the delegates belonging to the medical profession or engaged in teaching medical science were the following: Professor Fredet, of Clermont; Professor Saxtorph, of Copenhagen; Professor Hoffmann, of Dorpat; the Rev. Dr. Haughton, of Dublin; Professor Boddart, of Ghent; Professor Doijer, of Leyden; Professor Carpenter, of London; Professor Ask, of Lund; Professor von Pettenkofer, of Munich; Dr. Atherton, of New Brunswick; Professor Chiari, of Prague; Professor Thierfelder, of Rostock; Professor Cleve, of Upsala; Professor Mendeleeff, of St. Petersburg; Dr. Billings, of the University of Pennsylvania; Professor Virchow, of Berlin; Dr. Moore and Dr. Wheeler, of Dublin; Dr. Balfour, Dr. Smith, and Dr. Mitchell, of Edinburgh; Dr. Fergus, of Glasgow; Dr. Sieveking, Dr. Wilks, Dr. Priestly, Dr. Duckworth, Sir Risdon Bennett, Dr. Bristowe, and Mr. Erichsen, of London; Professor Thurnburn, of Manchester; and M. Gueneau de Mussy, M. Pasteur, and Professor Ball, of Paris.

The honorary degree of LL. D. was conferred upon the following-named gentlemen: Dr. G. W. Balfour, of Edinburgh; Dr. Fordyce Barker, of New York; Dr. J. S. Billings, of the United States Army; Sir William Bowman and Dr. J. S. Bristowe, of London; Professor Chauveau, of Lyons; Sir Andrew Clark, of London; Dr. Thomas Crawford, of the British Army; Mr. J. E. Erichsen and Sir William Gull, of London; Dr. D. R. Haldane, of Edinburgh; the Rev. Dr. Haughton, of Dublin; Professor von Helmholtz, of Berlin; Sir William Jenner, of London; Dr. Thomas Keith, of Edinburgh; Mr. John Marshall and Dr. Henry Maudsley, of London; M. H. Gueneau de Mussy, of Paris; M. Ollier, of Lyons; Sir James Paget, of London; M. Louis Pasteur, of Paris; Dr. von Pettenkofer, of Munich; Dr. W. O. Priestly, of London; Sir J. W. Reid, of the British Navy; Dr. M. H. Saxtorph, of Copenhagen; Dr. E. H. Sieveking, of London; Dr. Rudolph Virchow, of Berlin; Dr. P. H. Watson, of Edinburgh; and Dr. Samuel Wilks, of London. The same degree *in absentia* was conferred on Professor R. W. von Bunsen, of Heidelberg; Professor S. D. Gross, of Philadelphia; Professor J. Henle, of Göttingen; and Professor J. Hyrtl, of Vienna.

The Royal Medical Society gave a reception in the afternoon, and in the evening the banquet took place in the Drill Hall. Although about thirteen hundred persons were present at the banquet; the arrangements were such as to secure perfect comfort. Among the speeches was one by Professor Virchow, who traced a connection between the modern revival of scientific medicine and the overthrow of ecclesiastical tyranny, and placed the medical magnates of the early days of the University of Edinburgh side by side with Vesalius and Paracelsus as having helped to win the first great victory over Galenism. He referred appreciatively to Harvey, Cullen, the Monros, the Bells, the Simpsons, Sir Joseph Lister, and other men of renown in British medicine, and showed a familiarity with their achievements which was very gratifying to his hearers.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
 D. APPLETON & Co.

Edited by
 FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 3, 1884.

THE MEETING AT WASHINGTON.

From all the indications that have come to our knowledge, we judge that the meeting of the American Medical Association, which is appointed for Tuesday, Wednesday, Thursday, and Friday of next week, will be one of the most largely attended of all that the association has held. In the first place, the meeting is to take place in a city that has ample accommodations for a large number of strangers, besides being an attractive place in itself. In addition, there are several institutions in Washington that thousands of medical men in all parts of the country must long have felt a strong desire to visit—the Army Medical Museum, the Library of the Surgeon General's Office, the Naval Museum of Hygiene, etc., to say nothing of the features of interest to them in common with all other citizens of the republic.

But it is not in undue measure to these extraneous attractions that the meeting will owe its success; work of an unusually profitable character has been laid out for the sections, the lists of papers to be read and of discussions to be held showing an array of names seldom found to figure on like occasions. All this speaks in praise of the selection made of the chairmen of the various sections, and indicates that those officers must have exerted themselves to an unwonted degree to be able to present the satisfactory programmes that foreshadow the work of the meeting. While much credit is due these gentlemen individually, we can scarcely doubt that they caught their inspiration largely from the honored president of the association, whose presence ought to be a tower of strength to the meeting.

An interesting feature of the meeting will be the fact of its being the first one held since the establishment of the association's journal. The members will feel that they have just cause for congratulating themselves on the admirable course which the journal has pursued during the first year of its existence, and they will feel, too, that their choice of the "father of the association" to be its editor has been abundantly justified by the dignified, kindly, and modest tone that has marked its editorial columns.

Some apprehension seems to be felt that a wrangle over the subject of ethics will mar the concord of the meeting. We are unable to see the ground for this fear. Unless the question is broached by the president in his annual address, it seems to us hardly likely to come up at all, for a motion to amend the code is almost the only occurrence that could legitimately bring it before the meeting. The indications are that some such device will be resorted to as proved so successful last year in keeping out all who were unwilling to sign a declaration which sub-

stantially bound them not to countenance any interference with the code. If this is done, there will be nobody in the meeting who is inclined to make a motion of the sort. When the rancor incident to the recent ethical struggle in the State of New York has abated, it will be found, we believe, that the true men of the profession all over the country are essentially in accord on the subject of ethics, their differences relating only to matters of policy. We think, therefore, that the association will be acting in the interest of ultimate harmony if it ignores the ethical question for the present.

STRETCHING THE SPINAL CORD.

A RECENT issue of Volkmann's "Sammlung klinischer Vorträge" embodies a paper read by Professor Hegar before a medical society of Freiburg, in which that author deals with certain nervous manifestations that often appear to be connected with pelvic disease in women. Special reference is had to those phenomena that affect the nerves springing from the lumbar portion of the spinal cord—such as pain in the region of the sacrum, various neuralgias and hyperæsthesias in the course of the ilio-inguinal, the genito-crural, and the pudic nerves, radiating pains in the nerves of the lower limbs, partial paralyses of the latter, a bearing-down feeling in the pelvis, and difficulty in urination and defecation. These he classes as lumbar-cord symptoms (*Lendenmarkssymptome*).

Notwithstanding the common association of these symptoms with uterine disease, the author questions if they may not often owe their origin to an affection of the cord itself, and alludes to the well-known fact that they frequently persist and require treatment after the cure of any pelvic disease that may be found associated with them. He calls attention also to the point in the clinical history so often brought out by patients, that the symptoms complained of date from an occasion when some unwonted strain was brought to bear upon the body, involving especially an exaggerated bending of the spine forward, and suggests that the primary effect of such a strain may have been exerted quite as much upon the spinal cord as upon any of the structures situated within the pelvis. At the same time, he has no disposition to underrate the efficiency of treatment addressed to the pelvic organs in alleviating the symptoms in question.

Struck with the mobility shown by the vertebral column particularly its lumbar portion, in the various postures assumed by patients to facilitate gynecological manipulations, and by certain researches bearing on the subject by Schultze and Meyer, the author performed a number of experiments on the cadaver, to test the question of the behavior of the spinal cord under the influence of forced flexion of the vertebral column. Several of these experiments are related in detail, among them the following: The dura mater was exposed by removing the arches of the vertebra of a cadaver lying prone on a table. Two points, 125 mm. apart, were marked on the dura by means of threads, and the two corresponding points in the bodies of the vertebrae by needles driven into the bone. On moderate flexion, the two points on the dura were found to be 130 mm.

and those on the vertebræ 132 mm. apart. On more decided flexion, the points were separated to distances of 132 and 133 mm., respectively.

Continuing the inquiry in another direction, Hegar found that a notable stretching of the spinal cord was the result of traction on the sciatic nerve, and the question is suggested, whether many of the effects observed after nerve-stretching may not really be due in some measure to the accompanying stretching of the medulla.

The author has devised methods of stretching the cord in the living subject, and has employed them therapeutically with advantage. At present, he remarks, it is advisable to proceed cautiously with such procedures, for we have little more than empirical observation to guide us, and it is well to select cases as uncomplicated as possible, especially with disorders of the general health or of the sexual organs. The manipulation consists in the forcible approximation of the head and the knees. The lower limbs being held straight and stiff on a firm table, the head may be drawn down toward the knees; or, with the patient lying on the back, the limbs may be raised. In either case there must be no bending of the knees, for that would allow of such an amount of motion at the hip joints as to defeat the object in view. The patient should not be anesthetized, for the amount of pain produced is to be taken as a guide to the degree of force it is safe to employ.

Individuals differ decidedly in the degree of flexion that can safely be practiced upon them, and the degree increases as the manipulation is repeated. The author points out that a gymnastic exercise known as "*das Azthaven*," which, he thinks, must have somewhat the same effect as his manœuvres, was recommended by Schreiber for incipient paraplegia; but this fact, we fancy, will not lead the reader to deny the originality of Hegar's proposal. It would be interesting to know how the patients like the treatment; for ourselves, we think we should prefer to bear any ordinary infliction.

MINOR PARAGRAPHS.

A NEW JOURNAL OF OPHTHALMOLOGY.

WE have received the first number of the "*American Journal of Ophthalmology*," dated April 15, 1884. It is published in St. Louis, and edited by Dr. Adolf Alt, of that city, in conjunction with an able corps of collaborators. The journal is to be issued in monthly numbers, of thirty-two pages each. The April number contains two articles by the editor, one by Dr. F. C. Hotz, one by Dr. Henry Ferrer, one by Dr. H. Culbertson, one by Dr. S. C. Ayres, and one by Dr. Henry Schwarz. These papers are largely clinical in their nature, and of great practical interest. The journal is handsomely printed and altogether of pleasing appearance.

NEWS ITEMS, ETC.

MIRYACHT.—The "*British Medical Journal*" for April 19th contains Dr. William A. Hammond's article on this curious affection, being the same article that we gave in our issue of February 16th.

PROFESSOR SAMUEL D. GROSS, OF PHILADELPHIA.—We regret to learn that Dr. Gross is at present the subject of an illness

that is considered serious. His speedy convalescence was looked for last week, but a distressing gastric disturbance afterward occurred, and occasions some anxiety.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending April 29, 1884:

DISEASES.	Week ending April 22.		Week ending April 29.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	10	1	7	0
Typhoid Fever	10	4	8	4
Scarlet Fever	100	13	103	16
Cerebro-spinal meningitis	0	0	4	3
Measles	78	2	87	9
Diphtheria	49	18	41	16

THE YELLOW-FEVER QUARANTINE.—The quarantine service has already been established at Ship Island and at Sapelo Sound, Ga., and it is announced that it will be put in operation at Cape Charles on the 15th inst.

A SUMMER HOSPITAL FOR CHILDREN, designed to accommodate about thirty patients, is in contemplation by the people of Rochester, to be built on the shore of Lake Ontario.

THE HARVARD MEDICAL SCHOOL.—It is announced that Dr. Robert T. Edes has been appointed professor of clinical medicine, to succeed the late Dr. Calvin Ellis.

THE NEW YORK CANCER HOSPITAL is reported to have received a gift of \$200,000 from Mr. John Jacob Astor, together with a number of smaller sums from others. We understand that land has been bought for the purposes of the hospital in the vicinity of the Central Park, on Eighth Avenue, and that work will soon be begun on the buildings.

THE NEW YORK SKIN AND CANCER HOSPITAL held its annual "Kirmess" at the Metropolitan Opera House on Tuesday of this week.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—We learn that the college is to lose the services of Dr. William H. Welch, the present professor of pathological anatomy and general pathology and demonstrator of anatomy, on account of his having accepted a position in the Johns Hopkins University. We understand also that Dr. Gaspar Griswold has been appointed demonstrator of anatomy.

THE MEDICAL DEPARTMENT OF THE WESTERN RESERVE UNIVERSITY, OF CLEVELAND, is to have a new building. Among the additions to the necessary fund is one of \$10,000 from the estate of the late Mr. Hurlbut, whose large bequest to the City Hospital we lately recorded.

A PRIVATE HOSPITAL FOR DISEASES OF THE EYE.—We are informed that Dr. Thomas R. Pooley will open his private hospital, at No. 107 Madison Avenue, about the middle of May, and that complete preparations are being made for the proper nursing and care of patients.

THE AMERICAN CLIMATOLOGICAL ASSOCIATION will hold its first annual meeting in Washington on Saturday and Monday, May 3d and 5th. The following papers are announced: Opening Address, F. I. Knight, M.D., Boston; the Etiology of Pulmonary Phthisis, B. F. Westbrook, M.D., Brooklyn; Dryness and Elevation the Most Important Elements in the Climatic Treatment of Phthisis, Charles Denison, M.D., Denver; Some Observations on the Diagnosis of Pulmonary Diseases, D. N. Kinsman, M.D., Columbus; the Effects of Humidity on the Cause and Course of Diseases, W. H. Geddings, M.D., Aiken; the Effects of Sea Air on Diseases of the Respiratory Organs;

Boardman Reed, M. D., Atlantic City; the Use of Compressed and Rarefied Air, as a Substitute for Change of Climate, in the Treatment of Pulmonary Diseases, J. Solis Cohen, M. D., Philadelphia; the Constituents of Climate and their Relation to Disease, J. H. Tyndale, M. D., New York; the Relation of Laryngeal to Pulmonary Diseases, F. H. Bosworth, M. D., New York; the Climate of Large Cities Dangerous to Consumptives, Frank Donaldson, M. D., Baltimore.

UNWHOLESOME WELLS IN BROOKLYN, to the number of ninety-two, have been ordered to be closed by the Board of Aldermen, having been condemned by the Board of Health.

THE CONTAGIOUS CATTLE DISEASES BILL, providing for the "Bureau of Animal Industry," has passed the United States Senate with some amendments, chiefly the reduction of the appropriation to \$150,000.

A CHOLERA SHIP OFF THE ENGLISH COAST.—The British troop ship Crocodile, from India, is reported as in quarantine at Portsmouth, having had eight cases of cholera on board since she left port, six of which proved fatal.

THE STATE LUNATIC ASYLUM AT UTICA.—The legislative committee appointed to inquire into the alleged abuses at this institution has presented its report, and the document contains serious charges in regard to the management of the asylum, both from a business point of view and as regards the care of the patients.

THE IMPORTATION OF RAGS FROM EGYPT.—The Secretary of the Treasury has issued the following circular for the information of collectors of customs and others:

The following letter to this department from the Secretary of State, dated April 16, 1884, is published for your information and guidance, and, until further notice, rags from infected ports will not be permitted to land except under the provisions contained therein:

(COPY.)

"I have the honor to say, in connection with previous correspondence in relation to the proper disinfection of rags imported into the United States from Egypt, that the department has, upon careful and mature consideration of the subject commensurate with the interests involved, decided upon the following methods of disinfection, either of which will be satisfactory to the health authorities of New York city, New Haven, and Boston, who have been consulted in respect to the matter, viz.:

"1. Boiling in water for two hours under a pressure of fifty pounds per square inch;

"2. Boiling in water for four hours without pressure; and

"3. Subjection to the action of confined sulphurous-acid gas for six hours, burning one and a half to two pounds of roll brimstone in each 1,000 cubic feet of space, with the rags well scattered upon racks.

"Full and explicit instructions have accordingly been given to Mr. George P. Pomeroy, our agent and consul-general at Cairo, and Mr. Francis McNally, a citizen of the United States, has been designated as the inspector. He will have immediate supervision, under the consul-general, of the process of disinfection, will be required to give the subject his earnest personal attention, and furnish a proper certificate. Mr. McNally's certificate will show the following facts:

"1. His name;

"2. The name of the consignee in the United States;

"3. The place where the rags were disinfected; and

"4. The process of disinfection, which must be one of the processes hereinbefore described.

"After that the consul-general is to authenticate the certi-

ficate given by the inspector. This process is to be observed in the case of every bale of rags, which is also to be marked 'Thoroughly inspected,' with the name of the inspector.

"Mr. Pomeroy has been told that, although he should not refuse to certify invoices even when lacking the inspector's certificate, he must give notice to all shippers of rags that these goods will not be permitted to enter the United States unless accompanied by such certificate."

PROFESSOR BACCCELLI, OF ROME, formerly the Italian Minister of Public Instruction, has resumed his clinical lectures at the Ospedale di S. Spirito, as we learn from the "Gazzetta degli Ospitali."

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 20, 1884, to April 26, 1884:*

HOFF, JOHN VAN R., Captain and Assistant Surgeon. To be relieved from duty at Alcatraz Island, California, and to report to the commanding officer at Fort Mason, California, for duty as passed surgeon. Par. 3, S. O. 45, Headquarters Department of California, April 16, 1884.

PORTER, JOSEPH Y., Captain and Assistant Surgeon. Granted leave of absence for two months, to take effect about May 5, 1884. Per S. O. 38, Headquarters Division of the Missouri, April 19, 1884.

BIAET, VICTOR, Captain and Assistant Surgeon. Granted leave of absence for one year on surgeon's certificate of disability, with permission to leave the Division of the Missouri. Par. 2, S. O. 91, A. G. O., April 19, 1884.

LA GARDE, LOUIS A., Captain and Assistant Surgeon. Granted leave of absence for one month, with permission to apply for two months' extension. Par. 1, S. O. 91, A. G. O., April 19, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending April 26, 1884:*

HIBBERT, C. T., Passed Assistant Surgeon. Ordered to U. S. iron-clads, James River, Va.

AULICK, H., Passed Assistant Surgeon. Detached from iron-clads and ordered to the New Hampshire.

DIXON, W. S., Passed Assistant Surgeon. Detached from the Hartford and ordered to the coast-survey steamer Hassler.

TERRELL, F. H., Passed Assistant Surgeon. Detached from the Hassler and ordered to the Hartford.

WISE, J. C., Surgeon. Detached from the New Hampshire and placed on waiting orders.

SCHOFIELD, W. K., Medical Inspector. Appointed Medical Inspector on active list.

NASH, F. S., Passed Assistant Surgeon. Detached from Laboratory and ordered to the Alert (Greely Relief Expedition).

HALL, J. H., Passed Assistant Surgeon. Ordered before Retiring Board.

NELSON, H. C., Medical Inspector. Placed on retired list.

BATTLE, S. W., Passed Assistant Surgeon. Placed on retired list.

TERRELL, F. H., Passed Assistant Surgeon. Resigned.

MURRAY, J. M., Passed Assistant Surgeon. Ordered to the Minnesota.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, May 5th:* Association of American Medical Editors (Washington); Medico-Chirurgical Society of German Physicians; Morrisania Medical Society (private); Brooklyn Anatomical and Surgical Society (private); Utica Medical Library Association.

Tuesday, May 6th: American Medical Association (Washington—first day); New York Obstetrical Society (private); New York Neurological Society; Buffalo Medical Association;

Ogdensburgh Medical Association; Medical Societies of the Counties of Hudson (annual) and Mercer, N. J.

Wednesday, May 7th: American Medical Association (second day); Medical Society of the County of Richmond, N. Y.

Thursday, May 8th: American Medical Association (third day); Society of Medical Jurisprudence and State Medicine; Harlem Medical Association (private); Brooklyn Pathological Society.

Friday, May 9th: American Medical Association (fourth day); Yorkville Medical Association (private); Medical Society of the Town of Saugerties, N. Y.

Saturday, May 10th: New York Medical and Surgical Society (private).

OBITUARY NOTES.

PROFESSOR WILLARD PARKER.—The fear expressed in our last issue was speedily shown to be well founded; before the journal had reached the great majority of its readers, Dr. Parker's death had occurred. It took place on Friday afternoon of last week, the 25th inst. Concerning his last illness, there is nothing to be added to the information we have already given our readers. The funeral took place on Monday, the 28th inst., and was very largely attended by the profession of New York, as well as by a great number of friends of the family. The interment was at New Canaan, Conn., in which town Dr. Parker had spent many of his summers for a number of years past.

Willard Parker, M. D., LL. D., was born in Hillsborough, in the State of New Hampshire, September 2, 1800, being descended from one of the English families that took part in the settlement of the town of Chelmsford, Mass. When he was five years old, his parents removed to Chelmsford, where he obtained the rudiments of his education, and where, when nineteen years old, he himself took charge of a district school, by which means he prepared himself, both mentally and financially, for the academic course at Harvard University, from which he was graduated in 1826. It is said that, during his freshman year in college, he was led to give much thought to the art of surgery by having had occasion to admire the skill with which Dr. John C. Warren, at that time the professor of surgery in the Harvard Medical School, diagnosed and reduced a strangulated hernia in the person of one of his classmates.

Having entered upon the study of medicine, he spent two years as house physician to the United States Marine Hospital at Chelsea, Mass., and afterward became a private pupil of Dr. Warren's and an assistant in the anatomical department of the medical school. In 1829 he was appointed a house pupil at the Massachusetts General Hospital, and the next year he received the degree of doctor in medicine from the Harvard Medical School. He began his career as a teacher at once, lecturing first on anatomy in the medical school at Woodstock, Vt., at that time an important institution. He was then appointed professor of anatomy, and subsequently of surgery, in the Berkshire Medical College, at Pittsfield, Mass. In 1836 he went to Cincinnati, having accepted the chair of surgery in the Cincinnati Medical College. There he was closely associated with Dr. Samuel D. Gross, now of Philadelphia. He left his work in Cincinnati to continue his studies in Europe, and, on his return to this country, it was his intention to resume practice and teaching in Cincinnati, but the state of his health was such as to determine him to settle in New York.

In 1839 he was appointed professor of surgery in the College of Physicians and Surgeons, a position which he held until 1870, when he was made professor emeritus. When the old almshouse was converted into Bellevue Hospital, in 1845, he was made one of the surgeons to the hospital, and in 1856 he received a like appointment at the New York Hospital. In

these two hospitals, and as a clinical teacher at the College of Physicians and Surgeons, the great work of his life was performed, although at various times he was connected with a number of other hospitals, and was a member of all the chief medical societies of the city. When the Metropolitan Board of Health was created, in 1866, Dr. Parker was appointed one of the commissioners, the others being Dr. Stephen Smith, the late Dr. John O. Stone, and Mr. Jackson H. Shultz.

Dr. Parker was a general practitioner, and to the last he doubted the propriety of specialties, but his excellence as a surgeon led to a decided preponderance of surgery in his practice, and for a long term of years he was the leading surgeon of New York. Although he had a wonderful knowledge of anatomy and of the principles of surgery, he was not what is generally understood as a "well-read man." He rarely quoted authors, but he was seldom at a loss to bring his own immense experience to bear upon any rare case that chanced to come up in practice. He was not bound by empiricism, however, but always sought to correlate the facts which he observed, displaying an originality and an ingenuity that never failed to impress those with whom he came in contact. He was exceedingly exact as a diagnostician, but his methods of diagnosis were not those of the books, and, whenever his conclusions were questioned, he was apt to support them with arguments that few other men would have thought of, but that carried with them irresistible weight. His strong point as a practitioner was his unerring appreciation of the leading feature in cases where others were apt to be confused by minor details. In addition, he always recognized that his function was to treat the patient rather than the disease.

As an operative surgeon, Dr. Parker was appreciated aright only by the few who had seen him operate a great many times, for in ordinary operations he displayed none of the dash, precision, and neatness that were to be found in many of his inferiors; his stumps were not apt to look "nice," for instance. But in rare operations his *technique* was faultless and his precise knowledge of anatomy conspicuous. It is related of him that, while yet a young man, in Cincinnati, he was one day doing an operation that called for unusual care and skill, when an ill-natured bystander called attention in a whisper to the fact that his hand trembled, whereupon the late Dr. Muzzey remarked that he wished his own hand would "tremble in the same way." The glamour of an operation never seemed to have the slightest charm for Dr. Parker; he regarded the procedure only as an incident in a defined plan of managing disease or injury, and he never lost an opportunity to impress upon young practitioners the relative unimportance of operative work. To the intensity of his convictions in this regard it is no doubt due that he was not a seeker after novel methods, so that his treatment of vesical troubles by cystotomy and his operation for perityphlitis are almost his only noteworthy achievements in this direction.

As a teacher, Dr. Parker was distinguished for his earnestness and for the aptness of his illustrations. In his lectures he taught principles, paying little attention to matters of detail. His contributions to the literature of medicine were few. Early in his career he edited an American reprint of Cooper's "Surgery." His notes to the edition were very brief, but they were all to the point. His temperament fitted him for oral teaching, but he entertained something of contempt for those he termed "book-makers." His last contribution to medical literature, a short article on "Carbolic Acid in the Treatment of Wounds," was published in this journal for January 6, 1883. Dr. Parker always bore his full part in what he conceived to be the duty of the profession as teachers of the community, and on many occasions he gave public lectures, generally on subjects connected with hygiene.

As a man, Willard Parker was undeniably great. He was a typical democrat, impatient of all sorts of pretense and without a particle of diplomacy in his make-up. The kindliness of his manner was the direct reflection of his heart, as far removed as possible from courtliness or suavity, but aglow with genuine good feeling. His bluntness and his devotion to truth sometimes led him into hasty criticism of his fellows, but the pain he thus gave was always a source of unfeigned regret to him, and he never failed to make all possible amends. He supported his friends with a strong hand, and it is not too much to say of him that he was "the making" of many of his younger professional brethren. In his personal appearance Dr. Parker was a remarkably handsome man, and a man of great physical vigor and activity. These attributes, together with his joyous temperament, enabled him to inspire his patients with hope and courage; it was often said of him, indeed, that he could "put a smile on a dead man's face." Dr. Parker was a man of deep religious convictions, and his morality was spotless. His personal habits were exceptionally regular and correct. With all this, his ardent and hearty temperament made him dear to his family and his intimate friends, and attractive to all who came in contact with him. By his death both the profession of medicine and the community lose a strong man and a good man.

PROFESSOR J. B. DUMAS.—Our French exchanges announce that the death of this eminent chemist took place on the 11th of April, in the eighty-fourth year of his age. At a comparatively early age M. Dumas ceased his work as a teacher, but he will be remembered for his connection with the theory of substitution and for numerous contributions to physiological chemistry.

DR. JOHN M. CUYLER, OF THE ARMY.—Surgeon and Brevet Brigadier-General Cuyler died at his home, in Morristown, N. J., on Saturday, April 26th. He entered the army as an assistant surgeon in 1834. He served with honor and distinction during the late civil war, and received several brevets. At the time of his death he was on the retired list.

DR. CHARLES T. HUNTER, OF PHILADELPHIA.—Dr. Hunter, the demonstrator of anatomy in the University of Pennsylvania, died on Sunday, April 27th, in his forty-first year. He was a native of Ohio, received his preliminary education in New England, and was graduated in medicine from the University of Pennsylvania. He was one of the contributors to Dr. Ashurst's "International Encyclopedia of Surgery." His death is said to have been the remote result of a dissection wound.

DR. ROLPH D. MARSH, a graduate of the Medical Department of the University of the City of New York, in the class of 1879, died on Tuesday, April 29th, after a brief illness. For a time he was connected with the Reception Hospital in Ninety-ninth Street.

Letters to the Editor.

AFFECTIONS OF THE SKIN DUE TO BORAX.

79 BOYLSTON STREET, BOSTON, MASS.

To the Editor of the *New York Medical Journal*:

SIR: Will you kindly grant me the use of your correspondence columns to request from any physician who may have observed squamous or other pathological conditions of the skin following the internal administration of borax (whether for epilepsy or not) very brief notes of the cases for publication?

Treatises upon diseases of the skin do not appear to recognize such conditions, yet they have been observed in England by Gowers and other writers upon mental and nervous diseases, as also in Boston in this country.

Very respectfully,

EDWARD WIGGLESWORTH, M. D.

THE AMERICAN MEDICAL ASSOCIATION.

137 WEST TWENTY-SECOND STREET, April 29, 1884.

To the Editor of the *New York Medical Journal*:

SIR: The case of Dr. Allan McLane Hamilton, he having been asked to read a paper before the American Medical Association, and being afterward refused, is not isolated. A similar thing has happened to me in another section, only with the difference that the chairman of that section, after having requested me, in December last, to prepare a paper for the association, which invitation I accepted, wrote again to me, in the middle of January, informing me that he had received a printed statement of the standing of all the physicians in New York State on the code question. Learning that I belonged to the new-code or no-code party, he feared that I might be subject to unpleasant experiences if I offered to read a paper in the coming session of the association, and said that, in his judgment, I had better not fulfill my promise to him.

Dr. Hamilton's experience shows how friendly this advice was.

Yours, very truly,

H. J. GARRIGUES.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

Meeting of April 22, 1884.

CHARLES McBURNEY, M. D., Vice-President, in the chair.

ELEPHANTIASIS; LIGATION OF THE FEMORAL ARTERY.—DR. L. A. STIMSON presented a woman whose femoral artery he had tied four weeks before for elephantiasis of the leg.

She was fifty years old, and had always been healthy. Twelve years ago she had an attack of erysipelas in the foot, which soon got entirely well, but was followed after a month by another in the right leg, which left the limb somewhat swollen. Other attacks followed at intervals of two and three months for several years, leaving the limb larger after each attack than it was before. She was admitted to Bellevue Hospital, March 4, 1884, with marked elephantiasis of the right leg from the knee to the ankle, both the foot and the thigh being very œdematous, and the skin normal. She was kept in bed, firm pressure being made on the leg by roller bandages over a layer of cotton, and an elastic bandage was kept on the thigh. After about three weeks of this treatment the œdema had left the thigh, but the leg was unchanged, and still measured 23.5 inches in circumference. The other leg measured 8.5 inches at the calf.

March 24th the femoral artery was tied, at the apex of Scarpa's space, with catgut, and the limb wrapped in a thick layer of cotton.

April 2d the dressing was changed and the wound found healed. The leg measured 21 inches, and the foot was much less œdematous. The rubber bandage was then applied snugly to the leg over a layer of cotton, and had been used constantly to the present time, the patient being kept in bed. April 4th the leg measured 17 inches; April 8th, 14.75 inches; April 12th, 12.75 inches, which was its present size.

Dr. Stimson had refrained from using elastic pressure before the operation, because the books spoke so discouragingly of its efficiency, but he regretted now that he had not used it, even if

only to prove such inefficiency, and in a similar case he would give it a thorough trial before resorting to operation. At the same time he felt obliged to call attention to the rapid decrease of the œdema during the first week under the influence of the operation alone, and he thought it quite probable that the ligature and the bandage employed in concert had done much more than either would have done alone.

Dr. ALFRED C. POST had had a case several years ago of incipient elephantiasis in a person from the West Indies, in which great benefit followed continued pressure from the bandage. When the patient left, there was an approximation to an apparent cure.

Dr. C. K. BRIDGON had seen a case in the New York Dispensary several years ago in which there was considerable doubt as to whether it was one of obstruction of the lymphatics only or of true elephantiasis, but, at all events, marked benefit was afforded by the application of bandages wet with soda-water. The condition, however, returned in a measure, owing to discontinuance of the treatment and the return of the patient to his bad habits. If his memory served him correctly, Dr. Carnochan was the first to treat cases of this kind by ligation of the femoral artery.

Dr. J. L. LITTLE said that Dr. Carnochan's was the first case treated in this way, but only temporary relief was afforded.

Dr. E. L. KEYES said the opinion of dermatologists was against ligation of the femoral artery in the treatment of elephantiasis. The twelfth case of operation was reported by Mr. Buchanan, in the "British Medical Journal" for 1867, p. 465, who reported that nine had been cured, in two improvement occurred, and a third patient died of pyæmia from the operation. In the "Deutsche Zeitschrift für Chirurgie," 1876, thirty-two cases were reported. Of these there were twenty-three in which ligation of the femoral was performed, and of the twenty-three cases there were relapses in all except three. The consequence was that the operation was looked upon as one which might afford rapid amelioration in all cases, perhaps, but did not give a permanently favorable result. Dr. Carnochan's case ("Amer. Jour. of the Med. Sciences," July, 1867, p. 109) was one of elephantiasis Græcorum, which differed materially from elephantiasis Arabum, the malady treated in Dr. Stimson's case, and in most other cases of ligation.

Another case had been reported by Dr. Van Zetti,* in which the femoral artery was tied, a starch bandage was applied, and the patient was directed to go home and keep up the pressure by means of such a bandage for some time. At the end of three years the patient returned, having kept up pressure by means of the starch bandage continuously for the entire time, and the result was that the disease had become permanently cured and the limb was somewhat smaller than its fellow. Dr. Keyes thought that it would be proper to apply pressure not only to reduce the œdema, but for the purpose of maintaining continued pressure to prevent the disease from starting afresh. So far, then, as the present evidence stood, it was to the effect that the operation always was of benefit, but generally the benefit was temporary.

URETHRAL CALCULUS.—Dr. LITTLE presented a specimen, and said that, on the 26th of October, 1883, he had been called to see a boy, about twelve years of age, who gave the following history: The night before, while playing marbles in a stable, he received a severe contusion of the perineum by suddenly squatting down and coming in contact with the blunt end of an iron hook. This gave rise to considerable pain and straining, and he was unable to void his urine. In the morning, about nine o'clock, his straining efforts were followed by the passage of

blood and bloody urine. Dr. Gibney was called to see him, and, believing that a laceration of the urethra existed, sent for Dr. Little, who found considerable tumefaction and discoloration of the perineum and scrotum. The bladder was distended, and bloody urine dribbled from the meatus. On straining, clear blood, followed by a little urine, was passed. The sound was arrested just opposite the pubes, coming in contact with a substance which at the time was supposed to be bare bone. The patient was etherized, and a free incision was made in the median line of the perineum, through the œdematous tissue, until the urethra was reached. There was no extravasation of blood in the deeper tissues, nor could any laceration of the urethra be detected. The urethra was opened, a catheter was passed, and the bladder was emptied. The urine was discolored with blood. A probe, passed upward into the urethra, came in contact with a hard substance, which, when withdrawn with a forceps, proved to be a rough calculus.

When the patient was first seen, the symptoms, together with the incomplete history, plainly indicated laceration of the urethra. A more careful study of the case showed, however, that, as no blood followed immediately after the injury, but not until several hours later, while the boy was making some straining efforts to evacuate the bladder, it was plainly due to the passage of the calculus through the urethra, and not to the original injury. The patient made a good recovery in the course of six weeks after the operation, a good-sized instrument passing into the bladder without any obstruction. On inquiry, Dr. Little found that the boy had suffered from symptoms of stone for nearly two years, but, considering the size and the rough surface of the calculus, they had been very slight.

(To be concluded.)

BROOKLYN PATHOLOGICAL SOCIETY.

Meeting of March 13, 1884.

The President, Dr. B. F. WESTBROOK, in the chair.

DISEASE OF THE AORTIC, MITRAL, AND TRICUSPID VALVES.—THE PRESIDENT presented the heart of an unmarried woman, twenty-seven years old, who had suffered from aortic, mitral, and tricuspid stenosis and regurgitation. She was a bat-trimmer, who, ten years before her admission into St. Mary's Hospital, had an attack of rheumatism, and had since frequently suffered from wandering rheumatic pains. In April, 1883, she had a very severe attack, which was followed by great weakness, constant dyspnoea, cardiac palpitation, pain in the præcordia, and œdema of the lower extremities. There were also several attacks of syncope. When admitted, September 25, 1883, she was weak and pale, the feet and legs were œdematous, but not as decidedly so as they had been at times, and there was a small quantity of fluid in the peritoneal cavity. The dyspnoea was constant, the cough very troublesome, the pulse small, weak, and intermittent. She was obliged to remain in bed most of the time. The urine was slight in quantity, which was partly due to her taking very little nourishment; it contained a trace of albumin, but no casts were discovered. The apex-beat was in the sixth interspace, an inch and a half to the left of the nipple. It was weak. A double aortic murmur was easily made out. A mitral systolic bruit, transmitted into the axillary region, was also very easily detected. There was a presystolic murmur heard over the anterior surface of the heart, supposed to be connected with the mitral valve. But, in addition to these, a sound was heard along the left edge of the sternum, extending from the conus arteriosus downward to the inferior border of the heart, the rhythm of which could not be determined, owing to the rapid and exceedingly irregular action of

* "Gaz. des hôp.," No. 44, 1867, p. 572.

the heart. Three or four weeks subsequently, when the heart was acting more slowly and regular, the rhythm of the last-mentioned murmur was decided to be diastolic; and, on this account, together with the locality in which it was heard, it was thought to be indicative of pulmonic regurgitation.

The condition of the patient was but little affected by drugs, though both digitalis and convallaria did at times appear to have some beneficial effect. On December 1st Dr. Harrigan tapped the abdomen and removed about a gallon and a half of straw-colored serum, after which she felt better for a week or two. But the ascitic fluid reaccumulated, and on the 29th the tapping was repeated, and six quarts were removed. On January 8th she began to vomit incessantly. This continued with very little relief from the standard remedies, and she finally expired on the 11th.

Autopsy, by Dr. J. H. HUNT.—General appearance as described above. *Thorax*: The lungs were exceedingly small, not over half as large as those of an average adult. This was partly due to collapse of the lower lobes from accumulation of fluid (serosity) in the pleural sacs, each of which contained about a quart. There was very little bronchitis, and the lungs were not oedematous. The heart was large and round. The aortic and mitral orifices were very much contracted, the cusps amalgamated, and the valves incompetent. The mitral constriction was of the button-hole variety; the orifice would barely admit the handle of a scalpel. The tricuspid valve was thickened and the orifice narrow and funnel-shaped. It would admit one finger only. The pulmonic valves were unaffected. All the cavities, except the left ventricle, were dilated. The abdominal organs showed the lesions of chronic venous engorgement.

The case was interesting from a clinical and from a diagnostic point of view. The existence of disease of the valves of the right heart, always difficult and usually impossible of diagnosis, was evident; the difficulty was in deciding what valves were affected. The general symptoms would rather have pointed to trouble at the tricuspid orifice, for, with the amount of valvular disease present upon the left side, and the weak and irregular action of the heart, we should expect to find hæmoptysis, the most marked dyspnoea, and pulmonary oedema. But there was no history of hæmoptysis, no râles were to be detected on auscultation, and the dyspnoea, though pronounced and constant, was not nearly as great as was frequently seen in cases of mitral disease. Neither was the pulmonary second sound, heard at the left of the sternum, markedly accentuated. These circumstances would favor the view that there was some lesion of the right heart which prevented the access of blood to the lungs. Such a lesion would either be pulmonic stenosis, or tricuspid disease. But the rhythm of the murmur heard at the left edge of the sternum, which was diastolic so far as could be judged with the heart acting irregularly, seemed to decide the question in favor of the pulmonic regurgitation. There had been some discussion as to the existence of a diastolic murmur with stenosis at the auriculo-ventricular orifices, but the possibility of it was admitted. In this case there could be no doubt that either the mitral or the tricuspid stenosis had given rise to a murmur which was diastolic in its rhythm.

FIBROID DISEASE OF THE UTERUS WITH MARKED DISEASE OF THE HEART.—Dr. A. J. DOWER presented specimens, and related the following case: A married woman, thirty-six years old, called at his office, May 8, 1883, with the history that, for three or four months before, she had had partial amenorrhœa, with rachialgia, uterine colic, and, for a period of six weeks, tenesmus. Physicians who had examined her had told her that she was pregnant. As the symptoms continued, and as she was losing ground constantly, on consultation they thought it advisable to empty the uterus. A sea-tangle tent was introduced, but, al-

though some of the symptoms were relieved, including the leucorrhœa, the attempted abortion was not successful. After a short interval she was examined again, and again told that she was pregnant.

After hearing this history, Dr. Dower made a digital examination, and found the uterus enlarged to about the size proper to the third or fourth month of intra-uterine pregnancy, tender to the touch, and very hard. He told her he thought she was pregnant, and would probably miscarry in a short time. As she was anæmic and had dyspnoea, he examined her heart, and found that she had mitral stenosis and aortic regurgitation, also that the area of cardiac dullness was increased in both directions.

May 13th she went to New York, and on her return was taken with a single marked chill. He saw her the next day, and found that she had lobar pneumonia and slight pleurisy. The breathing was labored and frequent; the temperature was 102° F.; the pulse could not be counted then, owing to the very rapid action of the heart. Morphine and atropine were given hypodermically, and four hours of sleep were thus procured. The following day he asked Dr. Charles Jewett to see the patient with him. After hearing the history and making an examination, Dr. Jewett also came to the conclusion that the patient was pregnant, and, considering the marked organic cardiac disease, with the lung trouble, he anticipated an early abortion.

In a few days Dr. Jewett saw her again with Dr. Dower, when, considering all the facts in the case—that she was losing ground from hæmorrhage, etc., that there was such irritability of the stomach that she had to be nourished by the rectum, and that there was such extensive disease of the heart and lung—Dr. Dower suggested the removal of the uterine contents as the only means of preserving life. Dr. Jewett concurring in this view, Dr. Dower requested him to operate, which he did, dilating the cervix with Hanks's dilators and removing some placental debris (as was supposed at the time). While using the curette, he brought it in contact with a hard mass, and it was only then that the suspicion was aroused that she might have an intra-uterine tumor, either with or without pregnancy. The patient being very weak, it was deemed best to desist from the operation. The hæmorrhage ceased, as well as the vomiting, and on the 25th the patient took food *per vias naturales* for the first time, and felt very much better. The lungs began to clear up nicely, and gave her but little trouble. She improved daily until the morning of the 30th, when she was taken with sudden precordial pain, and died in a short time.

Autopsy, forty-eight hours after death, by Dr. W. J. BRANDT, present Dr. Jewett and Dr. Dower.—The body was fairly nourished, the abdominal fat being about an inch thick. The head was not opened. There was passive serous effusion in both pleural cavities, about equally distributed. There was a moderate amount of consolidation of the left lung, the right lung being normal. There was eccentric hypertrophy of the heart, with marked mitral stenosis and dilatation of the left auricle. The mitral leaflets were of leathery toughness and opaque; they led down to an opening that only admitted the little finger easily. The infundibulum and the cavity of the auricle were dilated to the size of a closed fist. There were evidences of recent endocarditis near the opening of the auricular appendix, with some roughening and deposit of fibrin. The auricular cavity was filled with soft, dark clot, not of an ante-mortem character. The muscular substance of the auricle was much attenuated. The aortic valves were roughened, thickened, and retracted to a moderate extent. The tricuspid valves were also markedly contracted and thickened. The uterus was retroverted, slightly flexed, and excessively rigid to the feel. At the fundus there was a small pedunculated subperitoneal fibroma, and several fibrous growths were felt imbedded in the walls of the organ,

each about as large as the one first mentioned. On opening the cavity, a large, pedunculated fibroma was seen growing from the left cornu. All the tumors were of nearly cartilaginous hardness, and presented no signs of activity. The mucous surface was smooth and hard. The uterus as a whole was increased in length. The os uteri was closed. The ovaries were normal. The ligaments were relaxed. The bladder was distended with urine. No microscopic examinations were made.

STRUCTURE OF THE URETHRA, WITH SECONDARY DISEASE OF THE BLADDER, URETHERS, AND KIDNEYS.—Dr. GEORGE V. CONVERY gave the following history of the case, as kindly furnished by Dr. Tieste, junior resident surgeon to St. Mary's Hospital:

L. C., aged fifty-three, born in Ireland, married, a laborer, was admitted January 11, 1884. When about twenty-five years of age he contracted a gonorrhoea, which, he says, was not properly treated. There was a purulent discharge from the urethra for some time, which gradually became thinner, and so continued for several years, when it stopped "of its own accord." After this he noticed that he passed a smaller stream, which of late years has been very fine, the urine dribbling away at times. About three weeks ago he saw a few drops of urine coming out through a fistulous opening in the scrotum, near its junction with the penis. This led him to apply for admission. Since then another opening has appeared lower down. There is a purulent discharge from these openings mingled with the urine. He was put upon the use of iron and quinine, to prepare him for operation.

January 17th.—He was anesthetized, and an examination was made. The circumference of the penis was a little over three inches and a half, corresponding to a urethra of 34.5 (Fr.); the meatus measured 28 (Fr.). A sound passed two inches and a half and was arrested. Only a filiform bougie could be passed through this stricture, and, after injecting the urethra with oil, and consuming half an hour in careful manipulation, one was finally passed into the bladder. Over this as a guide, Gouley's smallest tunneled sound was passed with difficulty through several constricted points and into the bladder. Careful attempts were now made to dilate the deeper portions of the urethra with Thompson's divulsor, so that the urethrotome might be passed and the operation completed, but unsuccessfully. On consultation with his colleagues, Dr. F. W. Rockwell decided upon external perineal urethrotomy as the only means of relief, although the possibility of serious renal disease was recognized. Therefore, the smallest tunneled sound was passed again as a guide, and the usual median incision was made. The perinæum was dense and cartilaginous, but the urethra was reached without much difficulty, and the deepest stricture, at four inches and a half, divided. After dilating with Thompson's divulsor sufficiently to introduce an Otis's urethrotome, the anterior stricture, at two inches and a half, and a deeper one, at three inches, were divided, and a No. 34.5 (Fr.) sound was passed into the bladder. Ten grains of sulphate of quinine and a quarter of a grain of sulphate of morphine were given, and the patient was put under the same treatment as before the operation.

18th.—The parts are washed night and morning with carbolized water. Liquid diet is given, including milk, beef-tea, and milk-punch. The urine passes entirely through the wound. A plug is left in the meatus.

19th.—A little urine has passed through the urethra.

20th.—There are no bad symptoms.

21st.—Dr. Rockwell passed a No. 33 (Fr.) sound. There has been no chill.

22d.—The wound is looking well.

24th. A No. 33 (Fr.) sound was passed.

25th.—Dr. Rockwell passed a No. 34.5 (Fr.) sound. There is slight diarrhoea. Ordered a two-grain opium suppository. The urine still passes mostly through the wound. The patient is weaker.

31st.—The bowels have not moved since the suppository was given, and he has no appetite. He takes milk-punch every two hours. He passes but little urine. Cups are applied over the kidneys, followed by a poultice of digitalis leaves. He is very weak and breathes stertorously, and the temperature is below normal this evening.

February 1st.—The urine is still scanty, and the cups and poultice are again applied. Ordered ten minims of tincture of digitalis every two hours. This morning he vomited a very offensive, thick, green fluid, the bowels moved involuntarily, and he died comatose at 2.45 P. M.

Autopsy, by Dr. HUNT, two hours after death.—The body was somewhat emaciated. The heart extended to the sixth intercostal space, and there were old pericardial adhesions on all its surfaces. The left ventricle was full of blood; the right one was collapsed. All the valves were thickened from old endocarditis. The lungs, the liver, and the alimentary tract were normal. The left kidney was large and white, the capsule peeling off readily. The organ was covered with cheesy masses about as large as pepper-grains. The pelvis and the ureter were much thickened and dilated. The right kidney was larger than the left one and more thickly covered with cheesy nodules, and here they were confluent. Several small ulcers were found on the cortical surface of this kidney. On section, the right kidney showed the pelvis ulcerated and full of a dirty, grumous-looking fluid, about an ounce in amount. The ureter on this side was about half an inch in diameter, and much convoluted. The bladder was very much thickened, its mucous membrane was greatly hypertrophied, and, from the contraction of the viscus, was thrown into folds so prominent as at first sight to look like calcareous deposits. The bladder contained a small quantity of fluid, of the same character as that found in the right kidney. The urethra was exceedingly tortuous and indurated. The perineal wound showed nothing abnormal.

Commenting upon the case, Dr. Convery spoke as follows:

"Without taking up too much of your time, it is my desire to-night, not to present a specimen of great surgical interest to a pathological society, but, instead, while giving all present the benefit of the case as a surgical one, to lay particular stress upon the morbid conditions secondary to or resulting from the urethral contraction. And, in discussing these morbid conditions, my aim shall be to follow, if possible, the retrogression of the somatic elements of the several organs; to show how, from the interruption to the flow of urine, the urinary organs became affected with functional arrangements, derangements that in turn produced textural lesions, until finally a condition resulted such as is shown in these specimens.

"The determination to follow the disease process from the beginning makes it necessary that we should determine where, after the interruption to the flow of urine, the effect of such interruption was principally felt. Did the obstruction to the flow of urine first cause a dilatation of the bladder and urethra, and then the pelvis of the kidneys, finally ending in inflammation and suppuration? Or did there occur a condition of hyperæmia at the neck of the bladder from the straining in the endeavor of the patient to void his urine, coupled probably with an old gleet and perhaps decomposing secretions of the prostate and that quantity of urine that almost always remains in the bladder when an obstruction exists, and, on the continuance of these conditions, the hyperæmia becoming an inflammation that ended in thickening of the vesical walls and ureters, and ultimately in inflammation and suppuration of the pelvis of the kidneys? This view of the production of the secondary disease is the most feasible.

"In this case, having an inflammation at the neck of the bladder in conjunction with the urethral strictures, giving numerous calls for micturition and great increase in the contractions of the muscular fibers to overcome the obstruction, hypertrophy of those fibers ensued; while from stagnating urine, or from contamination of decomposing urethral and prostatic secretions, the whole mucous membrane became affected. It became engorged with blood, there was increased energy in its histological elements, and consequently there was a great increase in the number of its cells, causing it to become much thickened and protruding as large folds or ridges.

"The hypertrophy of the muscular coats of the bladder was

a compensatory one, analogous to the hypertrophy of the muscular walls of the heart, that occurs in diseases which cause an obstruction to the flow of blood through the different orifices. If the patient had lived, and his strictures had continued as they were before the operation, his bladder would have in time presented another appearance; for muscular hypertrophy will go on to a certain point, and, having reached that point, will become stationary; if excessive work be put upon the hypertrophied muscular fibers, they lose their tonicity, and, becoming infiltrated with oil globules, undergo the phenomenon of fatty degeneration.

"The muscular fibers of the bladder interlace with one another, and around the intersecting points are spaces devoid of muscular covering. As the bladder distends, these spaces become more marked; and, as between the ridges of the mucous membrane are depressions which correspond with the bare spaces between the muscular fibers, diverticula or pouches are formed.

"From the obstruction in front, and want of contractile power behind to overcome the obstruction, the bladder would have become gradually distended, and, finally, a weak point would have been found, and, from the constant or nearly constant hydrostatic pressure, one of the pouches would have given way before the strain, and would increase in size until, instead of this small contracted bladder, we would have found, protruding from some part of the vesical circumference, a sac varying from the size of one's fist to that of a child's head.

"Regarding the ureters, from the small quantity of muscular or elastic tissue in them, very slight obstructions cause their dilatation; especially is this so if any inflammation of the mucous membrane exists, which paralyzes the contractile coat.

"In some cases the ureter may even attain the size of the small intestine (Rokitansky). With this dilatation we have hypertrophy of its coats, and, as it is increased in length, instead of being straight, it becomes coiled or bent.

"We have now, though perhaps in a cursory way, gone over the pathological physiology of the morbid conditions shown in this bladder and ureters; and it now remains for us to discuss those causes that lead to the changes shown in the kidneys.

"In the beginning, the obstruction to the flow of urine caused a certain damming back, and, with the dilatation of the ureters, we had also a dilatation of the pelves of the kidneys. Furthermore, this dilatation is greater than if the ureter was completely ligated. For, if the ureter was completely ligated, we would have a certain amount of dilatation, and then the hydrostatic pressure would become equal to the blood pressure and an equilibrium would be established; but in this case the pressure of the blood would endeavor to overcome the backward pressure, and the result would be, that to the already over-full pelvis another amount of urine would be added, yet not enough to equalize; the patient would then be called upon to micturate, and, upon the emptying of his bladder, the pressure in his renal pelves would suddenly be taken away, and the blood pressure in his renal vessels would be increased. So from hour to hour and day to day the equilibrium sought for could not be found, and the dilatation would go on.

"While this condition was going on in the pelves of the kidneys, in other parts another pathological phenomenon was taking place. For a moment looking at the physiology of the kidney, we find that the secretion of urine is dependent on the blood-vessels and certain parts of the kidney. These parts of the kidney are the Malpighian tufts and the uriniferous tubules.

"A system of capillary vessels enters the expanded portion of urinary tubules known as the Malpighian capsule, and the watery element and some salts of the blood are exuded, and trickle into the convoluted portions of the tubules. In a second

system of capillaries, surrounding the tubules which already contain a thin alkaline fluid, we have a membrane formed by the wall of the capillary and the delicate membrane of the tubule, a dense fluid on one side and a thin saline one on the other, conditions favorable for osmosis. And this osmosis takes place: some of the water given off in the Malpighian tuft is reabsorbed by the blood, and in its place the products of destructive metamorphosis go into the tubule, admixing with the water there, which becomes concentrated and is, in a word, urine. Besides this simple physical process in the elaboration of urine, a most important part is played by the epithelium lining the tubules.

"Heidenhain injected into the blood of animals indigo-carmin; he removed the kidneys at different periods after the injection, and examined them minutely. In not a single case did he find any indigo-carmin in the Malpighian capsules, but the epithelial cells lining the uriniferous tubules were filled with it.

"If we now consider for a moment, we shall see that, in such a case as the one I present, an immense amount of work was put upon the Malpighian tufts by the differences in the pressures, before and behind; that, from the sudden influxes of blood when the hydrostatic pressure was relieved, there were increased osmotic action and increased evolution of the epithelium of the tubules, so that the elaboration of certain elements might keep pace with the secretion of others; and that the epithelial cells were thrown off in an excess, and, not being carried away as rapidly in proportion, excited a peculiar form of inflammation stopping short of suppuration, and known as *anæmic necrosis*, or caseous degeneration. Little islands thus degenerated became the foci for degenerations of the connective tissue, which became affected with a like inflammation, until we have nodules deposited thickly over the whole renal surface.

"As for the ulcers, they may have been due, possibly, to septic emboli, but probably were the result of a breaking down of some of the cheesy nodules. The suppuration and ulceration of the renal pelvis was the result of decomposition of the urine in it, after inflammation, or possibly, through the urinary fistulæ or perineal wound, bacteria may have found their way, as is the opinion of Coats.

"If such was the case, they may have been the cause of the ulcers before attributed to a simple breaking down, and to reach the location of which they would travel up the uriniferous tubules."

Dr. GEORGE R. FOWLER referred to the fact that complete retention by stricture of the urethra was not necessarily present in every case of extravasation of urine and consequent urinary fistula. In the class of cases alluded to, the retention immediately preceding the extravasation was not due to a tight stricture, but to a swelling of the peri-urethral connective tissue, the result of a folliculitis occurring just behind and beyond a comparatively slight contraction of the urethral caliber. In such a case, ulceration of the follicle followed the folliculitis; the urine, not flowing freely past the point of ulceration because of an obstruction, slight though it might be, beyond the point, when the folliculitis occurred, slowly undermined the edges of the ulcer until the underlying connective tissue was opened into. Then followed cellulitis, swelling of the tissues, and retention. This latter condition, if not quickly relieved, led to further extravasation from the point of original ulceration, which in its turn increased the cellulitis. The course to adopt in such an emergency was obvious. It consisted in promptly relieving the retention, incising the tissues that were boggy and sodden and already inflamed, opening directly into the urethra in order to accomplish this, and then, with the divulsing urethrotome or some similar instrument, making sure that the entire urethral caliber was equal in size to that of the largest part of the membranous portion. Referring to the class of cases in which the stricture

preceding the retention was the result of a blow upon the perineum, attention was called to the certainty with which stricture followed such severe blows. This could be easily accounted for when it was considered what a complete counter-resisting force was offered by the pubic arch and the tense triangular ligament, and, consequently, what damage must be inflicted in this way. In this class of cases, stricture was quite certain to follow sooner or later. The urethra upon the vesical side of the coarctation became funnel-shaped, with its base toward the bladder; the urethral walls became more and more attenuated, owing to the damming back of the urine, while, *pari passu*, the bladder-walls became thickened more and more. In such a case but one thing could finally happen: the force from behind became more powerful, while the power of resistance along the dilated urethra became less and less able to bear the strain. A slight abrasion or superficial erosion at the site of a follicle or not, as the case may be, marked the spot where the wall of the urethra must finally give way.

The miseries of a man the subject of urinary fistula were indescribable. There could be no question as to the propriety of attempting relief in the class of cases under consideration, those in which even organic changes had occurred in the kidneys. In conclusion, Dr. Fowler related several cases in which he had succeeded in re-establishing the patency of the canal and in which the patient lived in comparative comfort for several years, despite the existence of organic disease of the kidneys as attested by the existence of albuminuria and the presence of casts in the urine.

H. N. READ, M. D., *Editor for the Society.*

Reports on the Progress of Medicine.

SURGERY.

By CHARLES B. KELSEY, M. D.

"GANGRÈNE GAZEUSE FONDROYANTE."—Dr. Trifaud ("Rev. de chir.," Oct., Nov., Dec., 1883) has published a careful and exhaustive study of a peculiar form of gangrene which has received many names, among which is the foregoing. The article is based upon one hundred and twenty-five cases, twelve of which were his own.

Definition.—"Gangrène gazeuse foudroyante" is a specific, infectio-contagious affection, having invariably a special origin. It is characterized, clinically, by a disorganization rapidly invading all the tissues with excessive premonitory pain at the point of inoculation, by progressive œdema and emphysema, a bronze color of the skin, extreme dyspnoea, fever of very short duration, etc. From an anatomical point of view, it is distinguished by the constant presence in the wounded region of a special microbe, inoculable in a series, which at first multiplies *in loco*, to subsequently spread through the whole organism.

Synonyms.—The multiplicity of names used to designate this affection has not tended to simplify its study, and none of them are now satisfactory, because of the more precise ideas which are at present held as to its nature. Among them are the following: "Emphysème gangréneux," or "empoisonnement traumatique" (Chassaignac), "érysipèle bronzé" (Velpeau), "pneumohémie putride" (Maisonnette), "gangrène foudroyante" (Maisonnette and Frery), "emphysème du moignon" (Salteron), "infection putride aiguë" (Perrin), "gangrena invadente" (Bottini), "septicémie gangréneuse aiguë" (Moraud), "gangrène foudroyante traumatique" (Jubin), "œdème aigu purulent" (Pirogoff), "pneumophlegmon" (Fischer), "septicémie

aiguë à forme gangréneuse" (Terrillon), "gangrène galopante" (Gosselin), and "gangrène gazeuse" (Mollière). Most of these names perpetuate an error, as will be shown, but, in order not to add to their number, the author adopts that of Mollière, at the same time declaring the expression "septicémie gazeuse foudroyante" to be more exact.

The history of this affection may be divided into four periods:

1. One finds here and there in the annals of surgery a few observations which appear to relate to the disease and which have been reported because of some interesting fact, such as the rapidity of their evolution or their extreme gravity.

2. From 1836 to 1870, according to the predominance of such or such local symptom, surgeons considered each of these as a particular and distinct complication of wounds (bronze erysipelas, primitive emphysema, etc.); no attempt to correlate these divers symptoms was made; they were not yet looked upon as the different manifestations of a single disease.

3. Since 1870 acute gangrenous septicæmia has been considered a distinct morbid entity, due to a general intoxication from the entrance of a septic vibrio into the body. It is a clinical variety of septic pyæmia, manifesting itself ordinarily by the bronze color of the skin, œdema, emphysema, etc.

4. "Gangrène gazeuse foudroyante" is an absolutely specific disease, always having for its origin an agent absolutely unique, distinct from the septic vibrio, and inoculable in a series. This complication, at first local, only affects the economy secondarily.

Symptomatology.—The prodromic phenomena have not the value which most authors have been inclined to attribute to them. The most important local symptoms are: spontaneous pain at the point of inoculation, subcutaneous œdema and emphysema, analgesia and increase of temperature in the part affected, the bronze color of the skin, and its rapid death. The general symptoms are less characteristic, manifesting themselves by the sinking of the patient, the premonitory dyspnoea, the acceleration of the pulse, and the fall of temperature soon after the appearance of the affection. The disease may appear in two different clinical forms. At first a local disease, it becomes generalized with greater or less rapidity. 1. A progressive general intoxication. 2. A rapidly developed (*foudroyante*) general intoxication. It should be considered as an unfortunate complication of wounds. It appears generally from the first to the third day after the injury. The gangrenous process always begins in the wound, and has an excessively rapid march, ascending without arrest. Its medium duration is from thirty to fifty hours. Without surgical interference, its constant termination is death. It has no seat of predilection, but may begin in any part of the body.

Pathological Anatomy.—The decomposition of the body is so rapid that a post-mortem examination, to be of any value, must be made very soon after death. The cadaveric changes are peculiar to the disease, differing as much from those of septicopyæmia on the one hand as from those of the different varieties of gangrene on the other. The blood is extremely diffuent, the tissues in the region of the wound are infiltrated with gas and fluids, and the presence of bacteria in process of evolution more or less perfect may easily be observed. The disease is a parasitic affection, and therefore contagious and infectious. The existence of a specific germ, far from being in contradiction to clinical observation, agrees with it perfectly. It is not an intoxication or a poisoning, but an infectious disease in which the blood and humors have virulent properties, as experience has demonstrated. The infection is not primarily general; the microbes develop at first locally at the point inoculated, thence to spread into the entire organism, and thus are explained the cures wrought by prompt surgical interference. Their way of propa-

gation is not yet very well understood. They seem at first to invade the neighboring tissues, then to penetrate into the circulation, either by the lymphatics or by the veins. There, plunged into a medium full of oxygen, they seem to develop imperfectly and are only found in the shape of spores; but, when they are deposited by the blood in other tissues more favorable for their development, they are seen to recover all their vitality, to multiply immensely, and to develop with rapidity. Thus is explained the rapid appearance of gangrenous spots at a distance from the wound which is the point of entrance, without alteration of intermediate tissues. In these cases the infection, at first local, is generalized with rapidity as a result of the rapid penetration of the germs into the circulatory current and their transportation to other parts of the body, into tissues not rich in oxygen, and therefore favorable to their development. By decomposing the albuminoid matter of the cellular tissue into which they penetrate, these ferments produce the formation of gas which is observed in the disease. As a result of their irritative action on the vaso-motor nervous apparatus of the invaded part, the œdema is explained which rapidly infiltrates the parts, the fluid being sero-sanguinolent.

Ætiology.—The inoculation and development of a specific germ are the only determining causes of the disease. The predisposing causes on the part of the wound are the existence of aufractuosities in a wound by crushing, and its recent production. On the part of the system, chronic alcoholism seems to be the sole predisposing condition. Crowding in hospitals provokes the epidemic development of the disease, and contaminated dressings are a very powerful agent in its production.

In *diagnosis*, the disease must be distinguished from certain grave forms of spreading moist gangrene due to compression or attrition of the tissues, to vascular and nervous lesions, etc. Their nature, their symptoms, and the prognosis are all different. It must not be confounded with diffuse phlegmon, acute purulent œdema, bronze erysipelas, gangrenous lymphangitis, dissecting wounds, infectious myositis, symptomatic charbon, or hospital gangrene.

Prognosis.—Although the disease may be considered as generally fatal, prompt surgical interference may save the patient in a few cases. The form designated by the title *intoxication générale foudroyante* is the most dangerous. If the temperature exceeds 41° C., or if it falls suddenly below the normal, any operation is useless; the patient is already deeply intoxicated. The farther the point of inoculation is situated from the trunk, the better are the chances of success. Chronic alcoholism leaves little for the surgeon to hope.

Treatment.—All medical treatment is powerless to arrest the progress of the disease. Large incisions are entirely powerless, as well as continued irrigations of alcohol and water, or phenic acid. Energetic cauterizations, deep and repeated, with the hot iron, extending beyond the infiltrated tissues, should be employed when amputation is impossible. Successes have been obtained by this method. The only treatment which generally offers any chance of success is amputation. The operation must be done as soon as possible, and in tissues not yet infiltrated. All the rules of the antiseptic method should be strictly observed. Alcoholic stimulants, including champagne, should be given in large doses. For prevention, the wounded should be completely isolated, amputated parts should be removed at once, the instruments used should be passed through the flame of an alcohol lamp, the different dressings should be burned, and the bedding should be disinfected with the vapor of sulphurous acid, the only efficient agent against the gaseous microbe.

THE AGGRAVATION OF DISEASES BY TRAUMATISM.—M. Verneuil (*Ibid.*, Jan., 1884) has recently advanced the idea that even the simplest injuries inflicted upon a person already sick

may aggravate the pre-existing affection and accelerate its course to a fatal termination. He believes that this effect is very evident and is not infrequently seen, and he gives as an example a case of latent cancer of the liver, in which a simple fracture of the thigh caused rapid aggravation of the disease and death in fifty-two days, although the fracture did perfectly well. As to the causes of the aggravation, he as yet expresses no opinion, but he believes the fact to be incontestable.

THE ANTISEPTIC INCISION OF HYDROCELE.—Dr. Julliard (*Ibid.*, Feb., 1884) reports fifty-four cases of the cure of hydrocele by an antiseptic incision. He performs the operation without any attempt at anæsthesia, either general or local, and does not find that the patients complain of any great amount of pain—not so much as is often the case with injections of iodine. The operation is short, the incision into the skin is alone painful, but it only lasts a few seconds, and the rest is no worse than the injection of iodine. Before the incision the part should be carefully disinfected with a very mild phenic-acid solution—one not sufficiently strong to irritate the skin. The operation is not one in which purulent infection is particularly to be feared, and, in addition to the weak antiseptic solution, the author uses only an abundance of warm water, which favors the operation by relaxing the parts. The region being thoroughly cleansed, the skin is drawn tight over the tumor and a long incision is made from above downward. His reasons for preferring a large to a small incision are: 1. The large incision is the only one which permits a proper inspection of the cavity of the tunica vaginalis, and this inspection is one of the chief advantages of the operation. Generally there will be found in the tunic or upon the testicle, cysts, foreign bodies, and exudations of different kinds, which require removal, and this can only be done by a large incision. 2. The large incision is the only one which allows of the resection and suture of the tunic to properly adjust it to the testicle and cord—an important condition from the point of view of the ultimate obliteration of its cavity. 3. The large incision heals as easily as a small one, if not more so.

The incision into the skin having been made, it is carried layer by layer down to the tunica vaginalis. Whatever bleeding there may be is controlled by pressure and torsion rather than by ligature.

The tunica vaginalis having been reached, a small incision is made into its upper part, into which the finger is introduced, and this is then enlarged with scissors till it equals in size that of the skin. The testicle and the inner surface of the tunic are then carefully inspected. Almost always there will be found either little cysts, foreign bodies, loose or attached, bloody or pseudo-membranous exudations, or calcareous or cartilaginous plates. The cysts are oftenest observed upon the testicle or the epididymis, more rarely on the tunica vaginalis or the cord. The foreign bodies, exudations, etc., should be sought for in every part. The cysts are excised with scissors, the exudations are removed with sponges, or, if necessary, with the curette. In a word, the cavity is freed of all the abnormal productions which it contains. This *toilette* should be made with care and with the use of the antiseptic solution already referred to. A strong disinfectant is absolutely proscribed, as it irritates the surfaces, augments the oozing, and interferes with primary union. From an antiseptic point of view it is useless; the spray answers every purpose, and this is used during the whole operation. The *toilette* being finished, the tunic is resected to an extent necessary to permit of the remainder just covering the testicle and cord, and it is then sutured. The sutures are of fine catgut placed 1 cm. apart. Thus complete apposition of the parietal and visceral layers is obtained. Care must be taken not to close the tunic until all oozing has been stopped. Cold may be used to accomplish this; the cavity may be filled with sponges; pressure

may be applied in any way, but strong applications and the cautery should be avoided as far as possible, lest they interfere with primary union. The use of drainage-tubes is not recommended. They are not necessary, and they absolutely prevent the union which is most desired.

After completing the suture of the tunic, that of the skin is performed. This is done with catgut, and a drain is placed in the lowest part. The dressing should be antiseptic, compressive, and unirritating to the scrotum.

This operation is compared especially with the injection of iodine. The latter is brilliant from its simplicity, but it exposes to inflammatory consequences the intensity of which can not be predicted; it sometimes fails, and more often it is followed by relapse. The antiseptic incision never causes violent inflammatory reaction, it is not more painful than the injection, does not call for anæsthesia, the wound heals as quickly, *it never fails*, and when well done there can be no possibility of relapse. Its only fault is that it is slightly more complicated than the injection. The supposed cases of injury to the testicle from obliteration of the tunica vaginalis are as likely to follow the one operation as the other. The author's fifty-four cases are given in full.

THE TREATMENT OF FRACTURE OF THE PATELLA BY WIRING.—Sir Joseph Lister ("Brit. Med. Jour.," Nov. 8, 1883) gives his experience in the use of the wire suture in cases of fracture of the patella, to which he was led by the use of the same treatment in cases of fracture of the olecranon. The treatment is particularly adapted to cases of ununited fracture, and to those in which there is considerable separation of the fragments from the first, which can not be overcome by the usual methods.

The operation consists in cutting down upon the bone by a vertical incision about two inches long, exposing the fragments, clearing out any clots or fibrous tissue which may stand in the way of their approximation or which may be within the joint, and applying a common bradawl in the middle line of the patella, drilling each fragment obliquely so as to bring out the awl upon the broken surface a little distance from the cartilage. Stout silver wire is then passed through the openings, and the fragments thus strung upon it are pushed firmly home, and thus brought accurately into apposition. Before they are brought together the following arrangement is made for drainage: A dressing forceps, with the blades closed, is passed from the wound made into the anterior part of the joint to the most dependent part of the outer aspect of the articulation. It is then forcibly thrust through the synovial membrane, the fibrous capsule, and the fascia, until its point is felt under the skin. An incision is then made with a knife through the skin on to the point of the forceps, so as to allow it to protrude. The blades of the forceps are then expanded so as to enlarge the opening thus made in the deeper structures without the risk of hemorrhage; the drain is seized in the protruding forceps and drawn into the joint. The ends of the wire are now twisted together, bent over, and pressed down into the bone so as not to interfere with the wound. All this is done with full antiseptic precautions.

The wire used is one sixteenth of an inch in diameter. The author has not found it best to use more than a single suture of such wire. It is applied in a vertical plane in the course of the longitudinal incision over the middle of the bone, and, in recent cases, no dissection of the soft parts over the patella is necessary. It seems important that the cartilaginous surface of the bone should be left quite smooth, or, in other words, that the fragments should be left quite level at their lower part. If the awl does not chance to come out at exactly the same level on the two fragments, this is disregarded until they have been strung on the wire, and then, on that side on which the awl has come out too far down, a little of the bone is chipped away

with the awl until the wire comes to be exactly opposite the hole on the other side.

The author reports several very successful cases treated in this way—cases in which a perfect joint was obtained.

A POINT IN INTESTINAL SURGERY.—Mr. R. F. Rand ("Lancet," Dec. 22, 1883) gives a valuable anatomical means of identifying the upper and lower ends of any given piece of small intestine. In those cases where an opening is made into the abdomen sufficiently large to admit the hand, the mesentery may be taken as a sure guide, if the attachment of its root be borne in mind. This attachment runs along the front of the spine in an oblique line from the left side of the second lumbar vertebra to the right sacro-iliac synchondrosis, and corresponds roughly to the long axis of the trunk. Above, it comes into relation with the upper end of the small intestine at the commencement of the jejunum; below, it leaves it at the cæcum. At the spine the two surfaces of the mesentery face right and left; farther out, their arrangement, like that of the bowel, is constantly varying. As we speak of a right and left surface as regards the mesentery, so we may as regards the bowel. It is difficult to identify the right and left sides of the bowel, but those of the mesentery are, at its root, self-evident, for here it is only about six inches in length, while at its periphery it is about nineteen feet. The right and left sides of the bowel having been identified, a knowledge of the upper and lower ends follows as a matter of course. The abdominal cavity having been opened at any point anteriorly, the first piece of small intestine presenting may be seized, its long axis being held in the long axis of the body, and its attached mesentery being pulled out tant from the spine, the hand may be passed, guided by the mesentery, backward to the spine, whence it may be passed upward and downward along its spinal attachment. If the bowel is being held in its true direction, the hand passed to the right of it will be conducted by the mesentery to the right side of the spine, and passed to the left of it, it will be conducted to the left side of the spine. But, should the apparent upper end of the bowel be in reality the lower end—in other words, should the piece be held in the wrong direction—the hand passed to the right of it will follow the twist of the mesentery to the left side of the spine, and *vice versa*. Nothing can be simpler than this in practice, and by it an operator may be saved from unnecessarily handling many feet of bowel to discover the anatomical relations.

THE RADICAL CURE OF UMBILICAL HERNIA.—Mr. Lawson Tait ("Brit. Med. Jour.," Dec. 8, 1884) gives some original ideas on the radical cure of exomphalus and other forms of hernia. The peculiarities of exomphalus—that the omentum is invariably present in the sac, that it is almost always adherent to the inner surface of the sac, and generally irreducible—have stood in the way of subcutaneous operations; and the extreme difficulty of being sure that the intestine is all reduced from the sac before the wires are tightened forms a serious danger in their performance. Another and still greater difficulty is found in the fact that it is almost exceptional to find a single hernial aperture. They are generally multiple.

Concerning the adhesion of omentum to the sac, the author does not agree with Mr. Wood that it would not constitute a serious objection to the operation by ligature, since the presence of an omental plug would contribute to the closure of the aperture, and strangulation of this structure by the ligature may be avoided in its application. The author believes that the retention of a piece of omentum in the ring would be a complete obstacle to the permanence of its closure. Mr. Wood also thinks that the presence of much permanent distension of the peritonæum by fat or from other causes would preclude any attempt at cure by a radical operation, and this in itself removes the great mass of sufferers from any hope of relief. A final

objection to all subcutaneous operations is that the utmost that is gained by them is the union of opposing surfaces of peritonæum, which is not at all likely to resist a stretching force for any length of time.

The author was first led to the operation he describes by being obliged occasionally to operate in cases of strangulated exomphalus. In such cases he has never done what is described as the extra-peritoneal operation, being convinced that it can not be so safe as the operation by opening the sac, and that it leaves the patient after recovery with a larger hernia than before. In eleven such cases he has opened the sac, freed all adhesions, removed redundant and irreducible omentum, pared the edges of the ring, and stitched them together. Every one of the eleven patients recovered. In three cases the cure of the protrusion has been permanent after eleven, eight, and five years, respectively. What has happened in the others he does not know.

Since the time when the author "discarded the superstitions of the peritonæum" he has turned his attention to the radical cure of exomphalus as one of the legitimate advances of his department. He has deliberately opened a number of hernial sacs, at or near the umbilicus, has reduced the intestine, cut off adherent omentum, pared the edges of the ring or rings, stitched them together by a continuous silk thread (which he leaves permanently), and has thus secured complete closure of the sac. Such an operation has had no mortality, and the results so far are all quite permanent. All the patients have been fat, some very fat, and one was pregnant.

He concludes by saying that he has an impression that the radical cure of other kinds of hernia than the umbilical will, by and by, be undertaken by abdominal section. A few weeks ago he removed an ovarian tumor from a woman with a femoral hernia in which intestine was adherent. It was a very easy matter to undo the adhesions, and by means of a handled needle and a silk thread to obliterate the ring in a manner which, he is sure, no operation from the outside could have effected. So much can be done through a two-inch incision that he thinks that in the future, should he be called upon to operate for a strangulated femoral hernia, he would proceed by abdominal section, and complete the radical cure of the protrusion at the same time that he relieved the obstruction.

Miscellany.

THERAPEUTICAL NOTES.—*The Treatment of Diabetes by Douches of Air.*—At a recent meeting of the *Paris Société de Thérapeutique*, reported in the "Progrès médical" for April 5th, M. Compardon alluded to three cases in which he had treated this disease by currents of air directed upon the vertebral column and the neck. In all the cases there was a notable diminution of the amount of sugar excreted with the urine. This amelioration was sustained, and was accompanied by improvement in all the other symptoms. Each douche was continued from five to ten minutes, but we find no mention of the frequency of their repetition, or of the temperature of the blast. The local effects are said to be a blanching of the skin and the formation of a cup-like depression, with a moderate reduction of temperature. After the douche, the skin becomes of a bright-red color, and remains so for three or four hours, during which time there is local sweating.

Resorcin in the Enterocolitis of Infants.—The "Progrès médical" quotes from the "Gazette hebdomadaire des sciences médicales de Montpellier" an abstract of an article, by Dr. Carreras, that appeared originally in the "Gaceta Médica Catalana," on the use of resorcin in the choleric form intestinal catarrh and the enterocolitis of infants. In

the former affection the results were not good, but some marvelous successes were achieved with the remedy in the latter. Eleven cases are reported, the patients' ages ranging from nine months to four years. Three of the infants were fed artificially, and one of these succumbed in spite of the treatment. The ten others presented the sub-acute type of enterocolitis, the symptoms being those that follow the acute form and precede the development of the chronic form. Strict attention being paid to the diet and the hygienic surroundings, resorcin was given every three hours. In three or four cases a strict milk diet gave rise to marked acidity, and bismuth, bicarbonate of sodium, pepsin, and Dover's powder were given in addition to that account. In every case improvement began in from four to six days. Eight of the eleven children recovered, and three died. The recoveries were very slow, with relapses. Dr. Carreras thinks that a remedy which, like resorcin, is at the same time astringent, antiputrescent, antiseptic, febrifuge, and capable of coagulating albuminous matters and modifying the surface of the mucous membrane, may be regarded as of the greatest utility against a disease in which most of the remedies thus far proposed fail.

THE LOUISIANA STATE BOARD OF HEALTH has been reorganized by the election of several new members, and the selection of Joseph Holt, M. D., to be its President. The Board now consists of Joseph Holt, M. D., J. C. Faget, M. D., L. H. von Gohren, M. D., L. F. Salomon, M. D., S. R. Olliphant, M. D., Charles E. Kells, D. D. S., Walter M. Smallwood, Esq., Joseph A. Shakespeare, Esq., and F. Formento, M. D. (resigned).

The following resolutions have been adopted by the new Board:

"Fully recognizing the wisdom of the quarantine laws of this State, the necessity of their rigid enforcement, and the great importance of securing for this Board the confidence of the people throughout the Valley of the Mississippi,

"Resolved, That it is the fixed and irrevocable purpose of this Board to apply quarantine restrictions against all ports where contagious or infectious diseases exist to the limit of the law, and, if necessary, it will advise the total suspension of all communications with such ports while so infected.

"Resolved, That, while we are guarding with sleepless vigilance the outlets of the Mississippi River, we are not unmindful of the dangers that threaten us from the rear. In more than one instance yellow fever has been introduced into this city and State through the States of Texas and Mississippi. All things considered, the least protected sections are the long lines of sea-coast westward in Texas, and eastward in the States of Mississippi, Alabama, and Florida. The approaches from without to this State are through Lake Borgne, the Mississippi River, and Berwick's Bay; these we will guard with sleepless vigilance, and while we are doing that we call upon the authorities of the States of Texas, Mississippi, Alabama, and Florida to exercise a like effective control over the sea-coast in those States.

"Resolved, That, while this Board will maintain its just prerogatives as a department of the State Government, it invokes the co-operation and confidence of any and all organizations at home and abroad that may be laboring to promote or protect the public health.

"Resolved, That, recognizing the great importance of securing the co-operation of the boards of health of other States, and of other health associations wherever situated, and of establishing a condition of absolute confidence, it is hereby made the duty of the President and other officers of this Board to extend to boards of health of other States, and other health associations, unrestricted access to the records and health reports of this Board, as well as the several quarantine stations as at the central office of this Board in New Orleans; and it is hereby further made the duty of the President of this Board to make public from day to day, as may be necessary, the condition of the public health, and he is hereby specially required, in the event yellow fever should be introduced into this city or State, to communicate such fact without delay to the exchanges and commercial bodies in New Orleans, and to the boards of health of other cities and States.

"Resolved, That the co-operation of the several exchanges and commercial bodies of this city is earnestly solicited in the sanitary work of this Board, and in the proper, intelligent, and effective application of the sanitary and quarantine laws of this State.

"Resolved, That, while tendering to other boards and health associations generally, at home and abroad, the courtesies and confidence of this State Board of Health, we solicit the like consideration of the boards of health and health associations of other States, to the end that confidence may not only be reciprocal, but established on a firm and enduring basis.

"Resolved, That, having thus declared our purposes and the policy of this Board, it is expected that no credence will be given, at home or abroad, to any reports respecting the state of the public health in this city or State, that are not sanctioned or verified by the action of this Board, or of its duly appointed officers."

MEDICAL EDUCATION IN GREAT BRITAIN.—In the course of a recent address to the graduating class of the medical department of the University of Glasgow, Dr. W. T. Gairdner, the professor of medicine, made use of the following language: "We by no means regard it [the discipline of the university] as perfect, but we do regard it as an effective, a sound, and a liberal discipline for the future practitioner of medicine. I take you to witness that it is in the main by honest, hard, steady work, and not by what is called 'cram,' that you have been able to pass with credit your examinations in this university. The four years of study through which you have passed have been really what they purposed to be. There have been no such abuses as we hear loudly complained of at the present moment in Dublin—sham lectures, sham certificates, irregular or perfunctory attendance. You know as well as I do that not one of these things would be tolerated for a moment in this, or I believe in any other Scottish university. Further, you know as well as I do that all your practical instruction, whether in the laboratory, the dissecting-room, the hospital, or the pathological theatre, has been, equally with the lectures, a regular, and therefore, we trust, an effective discipline. There has been no indefinite, and therefore valueless, 'walking the hospitals' permitted in the Western Infirmary. If any one has been idle or irregular there, it can not be said that any half-heartedness, or unpunctuality, or want of due control on the part of the teachers, can have been responsible for this; and most probably the idler in question has found his name among those which were not posted in the list displayed a few days ago at the college-gate, and represented by the faces I now see before me. Every step in your training has been carried on deliberately and steadily, from the first enunciation of the processes of a bone or the parts of a flower to the discussion at the bed-side, or in the clinical theatre, perhaps a week or two since, of the very last case admitted to hospital of pleurisy or of locomotor ataxy. And in each of the four examinations by which you have been tested I think I may frankly say that a perfectly genuine and honest effort has been made to do justice to every form of real capacity and diligence among you, and to eliminate those who were either incapable of learning or unwilling to learn in a regular and business-like manner. In the introductory address which I was charged to deliver at the beginning of the winter session, I claimed for the Scottish universities to 'have organized medical study into a regular discipline, at a time when, in England, before the passing of the Medical Act of 1858, the Bob Sawyer and Ben Allen type, or let us say the 'surgery boy' of the 'Times' article which I quoted, was still rampant and practically unchecked. I now claim for them—I, e., the Scottish universities generally, not this university in particular—the steady and progressive development, for more than twenty years past, of practical methods, both of teaching and examination, previously but little understood, and even now very imperfectly followed out by many examining boards. The object of this address is not polemical, and I am very far from wishing to make you medical politicians; but I may be permitted to say that we look with confidence to the Government to see to it that a system of discipline which has done so much for medical education in the past shall not be in any material point injured or subverted by legislation."

SARCOMA IN A CHILD'S SKULL.—In the February number of the "Æsculapian" Dr. A. Jacobi gives an analysis of the literature of this subject, and relates a case which he has met with. He finds that sarcoma of the skull in children is an exceedingly rare affection. His own case was that of a child, nearly four years of age, with a family history in which neoplasms were not altogether unknown, who had a

growth on the right parietal bone for six months. His mind was not well developed. The tumor was removed, and was found to communicate with the interior of the skull. Parts of the cranium were removed, and a portion of the dura mater, from which the tumor seemed to develop, four inches long by two inches and a half wide. The patient died on the eighth day, and the tumor was found to be a spindle-celled sarcoma. The dura mater and the bone contiguous to the tumor were both affected, spindle cells being found in abundance.

THE BITE OF A HORSE.—At a recent meeting of the *Société Anatomique* of Paris, M. Hartmann, an *interne des hôpitaux*, showed a man's thumb that had been bitten off by a horse, all but a delicate cutaneous connection which was divided when the wound was first dressed. The wound presented a large muscular stump, formed by the upper part of the first metacarpal bone, surrounded by contused masses of fleshy tissue, and the outer side of the second, also covered with muscular fibers. When the patient was told to move the thumb, the muscles of the stump were seen to contract. The wound was 10.5 cm. long by 9 cm. wide. On the dorsal aspect the skin was limited by a sharply defined contour, the thumb having been torn away about at the level of the second metacarpal bone; on the palmar aspect it was more contused. With the thumb a portion of the tendon of the extensor longus pollicis 21 cm. long had been torn away.

The report adds that this case seems interesting because: 1. It shows very clearly the double mechanism of wounds by the bite of the horse—by pressure lesions on the palmar side of the hand; by lesions of avulsion on the dorsal side. 2. Injuries of this sort are uncommon. In a paper read by M. Gillette, in 1876, out of sixty-six cases which that author was able to collect there were only four avulsions of the thumb, including three of avulsion of a tendon—two of the flexor and one of the extensor brevis, but in no instance of the extensor longus.

CONGENITAL LIPOMA.—In the "Archives of Pædiatrics" for February, 1884, Dr. A. Jacobi quotes Lancereaux to the effect that lipoma may and does occur congenitally. General obesity is not considered by him as an illustration of lipomatous development. The congenital form is chiefly found in the fingers, especially upon the volar side, and is developed only during the second half of fetal life. Less frequently it is developed upon the occiput, the back, the abdomen, the upper extremities, the calves of the legs, and the dorsal and plantar surfaces of the feet. The general proposition is that lipoma will develop under those circumstances and in those localities in which, under normal conditions, an extensive layer of fat is usually deposited. The growth of such a formation is slower in the adult, with an acquired tumor, than in the infant with a congenital one. The congenital form is oftener diffuse than encapsulated, in which respect it also differs from the acquired form. Five cases are narrated as the sum of the author's experience in connection with this subject. Some of the cases present points of great interest. Additional interest is given to the paper by an appended abstract of the literature of the subject. From this, as well as from the experience of the author, it would appear that the affection in question is a somewhat rare one.

THE VIRUS OF HYDROPHOBIA.—The Paris correspondent of the "British Medical Journal" (March 22, 1884), says: "M. Pasteur, aided by MM. Roux and Chamberland, have made a series of experiments on rabies. In a communication presented to the Académie des Sciences and Académie de Médecine, they state that, when the virus is directly introduced into the circulation, symptoms of paralytic rabies are manifested; but the peculiar noise like barking, accompanied by a state of fury, is absent. The virus has a decided tendency to become deposited in the encephalon and spinal cord; but it is also observed in some peripheral nerves—the pneumogastric and sciatic. It has also been observed in the submaxillary and sublingual glands. Under certain conditions the virus retains its toxic properties."

NARCOTICS AND "CELESTIAL HAPPINESS."—"A sect is said to have been discovered at Rostov, in South Russia, whose object is the poisoning of children by narcotics. It is believed to owe its origin to a woman who murdered her children 'in order to deliver them from earthly suffering, and to procure for them celestial happiness.'"—*British Medical Journal*.

Lectures and Addresses.

THE CARTWRIGHT LECTURES

ON

METHODS OF STUDYING THE BRAIN,

DELIVERED BEFORE THE ALUMNI ASSOCIATION OF THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK, FEBRUARY 2, 4, AND 6, 1884,

By BURT G. WILDER, M. D.,

PROFESSOR OF PHYSIOLOGY, COMPARATIVE ANATOMY, AND ZOOLOGY IN CORNELL UNIVERSITY, AND OF PHYSIOLOGY IN THE MEDICAL SCHOOL OF MAINE.

LECTURE III, PART I.

(Continued From page 461.)

Some Points in Encephalic Anatomy which are not Infrequently Overlooked or Misunderstood.

Porta (Foramen Monroi).—Perhaps no single feature of encephalic structure involves a greater number of morphological considerations or stands more in need of elucidation than the communications between the aulla and the proceliæ; certainly there is none which better illustrates the defects of the current methods of regarding, manipulating, describing, and figuring the brain, and the superiority of the methods advocated in the present course.

FIG. 54.—CAUDAL ASPECT OF A TRANSECTION OF AN ADULT HUMAN BRAIN AT THE CHIASMA. Drawn by Mrs. Gage. The cellie were anejected. After the section was made, parts were removed so as to display certain features more fully. The mesal cavity opened is the aulla, commonly described as the "anterior part of the third ventricle," or the "middle portion of the Y-shaped foramen of Monro." Ventrad of the precommissure, its cephalic boundary, is the terma, which is more fully seen from the outside in Fig. 51. Dorsad of the commissure are the two columns of the fornix, and between these a narrow cleft bounded cephalad by a part of the terma (see Fig. 14), through which, by accident, may be made a communication into the pseudocoele. On the right the thalamus is untouched, but on the left it has been cut out so as to show the corresponding porta with the portplexus hanging therein.

During the last hundred years the "Foramen of Monro" has been variously and incongruously described and figured

as a single orifice and as two; as a horizontal passage and as triradiate; as oval, semilunar, and nearly circular; as a hole and as a notch; as an independent foramen and as merely one end of the "great transverse fissure"; as both visible and invisible from the meson; as named after two anatomists, father and son, of the same name (which name is spelled in three different ways); and, finally, as having, in the human adult, a purely imaginary existence.

Its existence.—In 1783 Alexander Monro, *secundus*,* in describing the orifices in question, speaks as follows (p. 10):

"The most eminent of the late authors who knew the descriptions of former authors, and had particularly examined the subject, have doubted of or denied such communications of the lateral ventricles with each other, or with the other ventricles, or have so entirely overlooked or missed such communications that, in the figures they have given, they have not ventured to paint any of the places at which it had been said that they were to be found; and, as a proof that there is no natural communication, they have remarked that, in hydrocephalus internus, the water had filled only one of the lateral ventricles."

Since Monro, it is to be feared that many dissectors of the human brain have either failed to observe the orifices at all, or have carelessly confounded them with the artificial communication between the "lateral ventricles" and the "third," which is produced by removing the cerebrum from the subjacent parts. But it seems to have been reserved for a distinguished anatomist and physiologist to exemplify the outcome of imperfect morphological ideas and faulty manipulative methods by a formal and public denial of the existence of the "foramina of Monro."

As reported officially in "Le Progrès médical" for 1879, p. 483, in the "Société de Biologie, Séance du 14 Mai, 1879, Présidence de M. P. Bert," and at a later meeting, June 21, there was read by M. Mathias Duval a paper entitled "De la non-existence des trous de Monro." The following are characteristic selections:

"Sur la foi de tous les traités classiques d'anatomie on admet généralement que les trous dits de Monro font communiquer les troisièmes ventricles latéraux et qu'ils donnent passage aux plexus choroïdes. M. Mathias Duval a fait sur ce point d'anatomie de l'encéphale des recherches complètes, desquelles il résulte que les trous de Monro n'existent pas chez l'adulte. Lorsqu'on trouve sur un cerveau d'adulte une communication entre le ventricule moyen et les ventricles latéraux, cette communication provient d'une perforation artificielle. Chez l'embryon humain, comme chez les animaux inférieurs, les trous de Monro existent réellement, mais ils s'oblitérent plus tard. Enfin, selon M. Duval, il n'y a pas de plexus choroïdes dans le ventricule moyen."

Notwithstanding the reputation of Duval, the dignity of the learned society before which his communication was made, the tacit indorsement of his views by the society and the journals which have printed the paper, and the fact that, so far as I know, no one besides me has publicly protested against them, on the present occasion I shall content myself with briefly enumerating the various methods in which the

* The evidence that the porta was named for the second of the three Monros, and not for his father, as stated by Todd and by Littré et Robin, has been presented in my paper (±).

FIG. 55.—PART OF THE LEFT HEMISPHERE OF A CAT; ENLARGED. DRAWN BY PROFESSOR CLEVER. The cœlie were alinjected, and enough of the left hemisphere removed to expose the continuity of the cavities. The shaded portion represents the endymal or entocœlian surfaces, and the cut surfaces are left blank.

Besides the location and form of the porta, the figure shows (a) the continuity of the portiplexus with the proplexus, which is turned up from its attachment along the rim; (b) the non-extension of the proplexus to the tip of the medicornu; (c) the bifurcation of the cornu, which is unusually pronounced in this specimen; (d) the absence of a postcornu; (e) the slender extension of the præcornu into the olfactory lobe as a rhinocele.

portæ may be demonstrated upon the brain of man or of any other mammal, bird, reptile, or amphibian.

Modes of Demonstration of the Porta.—1. *Inflation.*

—If a brain is properly supported, as upon cotton, and air blown cephalad from the metacele, or any other cœlian division caudad of the medicommissure, the hemispheres will be coincidently expanded; or, if it be blown into either procele, the expansion will be produced in the opposite hemisphere, especially near the end of the temporal lobe; if the brain be under a liquid, and the procele be opened, the air will escape as bubbles.

2. *Injection of liquid.*—A colorless liquid serves the same purpose as air, but, if it contains colored particles in suspension, the staining of the cœlian lining will enable the observer to determine the course of the liquid and the non-rupture of the parietes.

3. *Injection of material capable of solidifying into a cast.*—As stated in Lecture II. (this journal, March 1, p. 234), wax casts of the human cœlie were made by Welcker in or before 1878, when he published his figures (1). Prior to my acquaintance with Welcker's paper, with the aid of Professor Gage, I had made plaster casts of the cœlie of a cat and sheep, and the porta of the latter was represented on each side as a narrow neck. These casts were shown at the meeting of the American Association for the Advancement of Science in 1880, and are figured in "Anatomical Technology" (Wilder and Gage, p. 458). More recently, the cœlie of the cat were injected successfully with the three compositions named in Lecture II.

Mesal exposure.—This is the method usually employed, yet it is perhaps the least desirable, for the simple reason that the porta in man, the cat, and mammals generally, is often nearly or quite invisible when the meson is squarely viewed. By looking obliquely, from caudad of the forni-

columna, the porta may sometimes be seen as an interval between it and the thalamus.

Removal of the mesal wall of the præcornu.—As indicated in "Anatomical Technology" (p. 456, Pl. IV, Fig. 16), if the mesal wall of the præcornu be removed by successive thin slices not quite reaching the terma and forniculuma, then a headed bristle or a probe may be passed from the cornu to the aula, or in the opposite direction.

Transverse sections.—If transections are made, they may be thick, excepting in the aulic region (nearly dorsad of the chiasma, where they should be so thin as not to include the cephalic and caudal walls of the portæ within the same slice. The best results are obtained by combining transection with dissection after the plane of the portæ is nearly reached.

Horizontal section of an alcoholic brain.—If either the dorsal or the ventral region of a brain be removed in successive slices, there will be exposed a condition of things more or less closely resembling what is shown in Fig. 7 (Lecture I, this journal, February 9, p. 146). The porta at each side opens from the aula into the corresponding procele. This method is best applied when the cœlie have been alinjected. The only danger is lest the slice at that level be so thick as to include both the dorsal and the ventral limits of the portæ.

Lateral exposure.—The brain is supposed to have been hardened and the cœlie alinjected. The lateral wall of the medicornu is first removed in successive slices, and its course followed by cutting obliquely until the præcornu also is opened. The striatum is removed with the lateral wall of the præcornu by an incision just laterad of its plane of junction with the thalamus. The porta then appears as a perfectly distinct orifice, through which a bristle may be passed

into the *aula* and *diacele*, and, if the opposite side be treated in like manner, into the corresponding *cella*.

FIG. 56.—PART OF THE LEFT HEMISPHERE OF A CHILD ONE TO THREE YEARS OLD. Drawn by Professor Cleaves.

The *cælie* were alinjected. They may have been distended somewhat by the pressure, and the contour of the parietes rendered less distinct. The procele is exposed by removing the lateral wall, and the porta appears as an orifice into which projects the portiplexus (*ppx.*). The proplexus continues therefrom along the rima.

So far as I know, this mode of examining the porta in its undisturbed relations was first employed by me in the preparation of a cat's brain. Later preparations of the cat are figured and described in **14**, Fig. 19, "Anatomical Technology" (Pl. IV, Fig. 19), and in the present lecture (Fig. 55) a similar method was employed with the child's brain (Fig. 56). This and the cat's brain had their *cælie* alinjected.*

Fresh dissection.—As a rule, as stated in Lecture II (this journal, March 1st, p. 236), the examination of any difficult feature upon a fresh brain should not be undertaken until skill has been gained upon alcoholic preparations. If the parts can be kept from tearing, the fresh brain has the advantages of displaying the natural color of the several portal boundaries, and of yielding to a certain extent so as to exhibit their connections in a better light.

The porta does not always appear at the meson.—In most figures of the mesal aspect of the hemiencephalon the "foramen of Monro" is represented by an oval or semicircular dark spot. Judging from the preparations made or examined by me, the porta is invisible when the human meson is perpendicularly viewed, and I have yet to see it in any other mammal. This is due to the obliquity of the corresponding surfaces of the thalami and the forniculonne.

Form and direction.—I have not yet satisfied myself as to the precise form of the *undistorted* porta in the adult human brain. It is certainly narrower than a circle and wider than a slit. Provisionally, it may be described as a somewhat irregular oval, the smaller end dorsad.

The direction of the axes will, of course, vary with the position of the brain, but, for convenience, the sides may be regarded as cephalic and caudal, and the ends as dorsal and ventral.

Dimensions.—In an adult human brain, the *cælie* of which were injected with alcohol, the height of the porta is 6 mm. Judging from Welcker's casts, it was about 4.5 mm. in the brain he employed. Its width is more variable and less easily determined, but seems to vary from 1 to 3 mm.

* Since this was put in type, I have been able to make a similar preparation of an adult human brain.

The points of reflection of the endyma upon the plexus are not always directly opposite, so that either the fornicul or the thalamic border of the porta may be longer than the other.

Relatively to the size of the whole brain, the porta is much larger in the cat than in man. In the former its width varies from 0.5 to 1 mm., and its height from 3 to 4 mm. Its boundaries are essentially the same as in man in all mammals examined by me. Its limits are most satisfactorily exhibited in vertebrates where the rima is but slightly developed.

Boundaries.—Passing over the confused or erroneous descriptions of earlier works and some recent ones, each porta is correctly described in Quain (ii, 321) and Gray (640) as between the "anterior" end of the thalamus and the corresponding "pillar of the fornix." Its caudal boundary is the thalamus, its cephalic boundary is the forniculonne, and its ventral limit is formed by the continuity of these parts.

Here the description ceases. So far as I know, the dorsal limit of the porta, the "upper end of the foramen of Monro," has never been indicated outside of my publications,* nor, indeed, does any other anatomist appear to have been impressed with the necessity of determining what that limit is, or even of ascertaining that one exists.

Notwithstanding this apparent indifference, I can not refrain from expressing the conviction—which has steadily deepened during the last seven years—that a dorsal limit of the porta not only exists, but is a morphological necessity, and that its recognition is essential to a clear comprehension of the macroscopic structure of the brain.

FIG. 30.—Two diagrams indicating the constitution of a simple plexus, and the manner of circumscription of the porta ("foramen of Monro") at the dorsal end of the reflection of the endyma upon the plexus.

That the porta is a completely circumscribed orifice is most satisfactorily demonstrated by means of a cast, the material being injected *per luvam* as described in Lecture II (this journal, March 1st, p. 235). The manner of its circumscription at the dorsal end may be determined by care-

* Four years ago, after repeated verifications of the portal boundaries in the cat and fairly satisfactory confirmation of the results upon the human material at my disposal, I prepared a paper upon the subject for presentation at the meeting of the American Medical Association in 1880. This was withdrawn in favor of papers of a more practical nature, but an abstract appeared in "The Medical Record" for August 7th. Substantially the same paper was read before the American Association for the Advancement of Science, August 29th (5), and illustrated by preparations and diagrams. The dorsal limitation of the porta was also indicated in papers (9, 136; 14, 558, Fig. 19), more fully described and figured in "Anatomical Technology" (459, Fig. 123), and demonstrated upon preparations of the human brain at the meeting of the American Neurological Association, June 23, 1883 ("Journal of Nervous and Mental Disease," July, 1883, p. 86).

ful dissection in any of the ways above indicated. Since the ventral end is simple enough, it may be opened from any direction. The interval between the thalamus and the fornix will then be seen to be partly occupied by a fold of pia, the portiplexus. The ventral border of this plexus hangs free, but, if the syringotome (Lecture II, p. 237) or some similar instrument of exploration is employed, and the plexus carefully pushed aside, first one way and then the other, it may be ascertained that the smooth endyma which lines the porta, like all other cœlian divisions, is reflected from the fornix upon the cephalic face of the plexus and from the thalamus upon its caudal face, and that in this way the dorsal end of the passage is closed as really and as effectually as if the plexus were not there at all, and the endyma were continued directly across from the fornix to the thalamus, as presumably it did in the embryo.

The porta, then, is a completely circumscribed orifice, a foramen with continuous parietes; but, while two sides and one end are bounded not only by endyma but by substantial masses, the dorsal end is limited only by the endyma as it is reflected upon the intruded plexus.

The porta and rima are different and distinct.—This follows from the foregoing description of the former, and from the now generally accepted description of the latter, as indicated in Fig. 31.* The porta is a primary, fundamental, and essential communication between the aula and either procele; the rima is merely a thinned-out line of the medicornual parietes through which the pia intrudes as the proplexus, and the latter hangs within the cornu just as the portiplexus hangs within the porta.

The difference between the porta and the rima may be roughly illustrated by comparison with a house, as suggested in Lecture I. Let the aula or primitive procele be represented by a small building, and each lateral portion by a larger one. Between the hall and the larger room at either side is a doorway. Suppose now that the substantial wooden wall of the larger building be removed, beginning with the

FIG. 31.—Diagram of a transsection of the medicornu ("cornu descendens"), showing the manner of formation of the proplexus, and the real closure of the rima by the reflection of the endyma thereon from the marginal taula and fimbria.

top of the door, but that there remain the paper lining and the paper covering of the same. Whether or not the latter project into the room, or the doorway, or the hall, or all three, the essential fact remains that the doorway is really limited at the top, just the same as if the wall at that place had not been removed.

The prevalent non-recognition of the dorsal limit of the porta is attributable to all the anthropotomical methods

* Schwabbe's Figure 314 represents the porta and rima as continuous and indistinguishable portions of an elongated fissure.

criticised in the present course: Roughness in removing and handling the brain; neglect of means of preserving the ental parts; adherence to conventional modes of dissection; unquestioning dependence upon published figures and descriptions; last, but by no means least, lack of morphological insight.

Original Communications.

SUPER-ALIMENTATION, ARTIFICIAL ALIMENTATION AND GAVAGE, AND THE EMPLOYMENT OF ALIMENTARY POWDERS, ACCORDING TO THE METHOD OF DR. DEBOVE.

By HENRY B. MILLARD, A. M., M. D.,

MEMBER OF THE MEDICAL SOCIETY OF THE COUNTY OF NEW YORK; VICE-PRESIDENT OF THE NEW YORK MEDICO-CHIRURGICAL SOCIETY; HONORARY MEMBER OF THE SOCIÉTÉ ANATOMIQUE DE PARIS, ETC.

(Continued from page 467.)

As to the employment of *lavage* in organic diseases of the stomach, there might be, in certain cases, danger of breaking down newly formed cicatricial tissue or delicate vascular walls, and producing hæmorrhage, but, undoubtedly, *lavage* can ordinarily be employed with advantage in contributing to the nourishment of the system in cancer or ulceration of the stomach. Although a cure be impossible, life may be prolonged and suffering assuaged. Broca ("Progrès méd.," October 7, 1882), giving the opinions and experience of Dr. Beaumetz, Germain Sée, Kussmaul, and others, shows that *lavage* with artificial alimentation may be ordinarily resorted to in cancer and ulcer of the stomach, whether the cancer be ulcerated or not. This method is sometimes the only one of detecting the presence or absence of organic disease. Cornillon ("Progrès méd.," November 17, 1883) gives an account of a case of hæmatemesis from ulceration in an alcoholic person where the hæmorrhage was brought back by throwing in a quart and a half of water, this occurring each time it was used. Care and judgment, however, must be used; *lavage* can not be employed indiscriminately in all cases, and the amount of liquid thrown in must vary.

Among the cases of *ulcer of the stomach*, in addition to those reported by Kussmaul, Bucquoy, and others, is that of Carjat, already referred to in showing the effect of super-alimentation. (Hôpital Bicêtre, service of Dr. Debove.) This patient, a man aged fifty-four, suffered from a simple ulcer of the stomach. He had had five or six severe attacks of hæmatemesis, in the intervals between which there was occasional vomiting of glairy mucus, with intense epigastric pains. In January, 1881, he was in a condition of marasmus, and seemed at the point of death. In six weeks, *lavage*, followed by alimentation by the tube, had brought about an entire cure of the gastric trouble, and he had gained 3.5 kilogr. The middle of March he left the infirmary, still feeble, however; he continued to practice *lavage* at his own home, which he did easily twice a day; was able to work; there were occasional pains, but no vomiting. At

the end of a few weeks he discontinued lavage, using it only when there was great heaviness in the epigastrium. The year after leaving the infirmary the patient became tuberculous, the ulceration returned, and artificial alimentation was employed by Debove, with the results before given (see page 465). This case shows that neither lavage nor super-alimentation is contra-indicated in simple ulcer during the period of cicatrization, there having been no hæmorrhages for a considerable time. Large quantities of food, however, introduced when hæmorrhages are liable to occur, might produce serious accidents.

In *alcoholic gastritis*, Dr. Beaumetz considers *lavage* sovereign ("Bull. gén. de thérap.," October 13, 1880). Dr. Constantin Paul has given a case, and Broca (*loc. cit.*) gives the following case at the Bicêtre, where the cure was prompt and complete:

Hamerlin, aged thirty-seven, admitted March 30, 1882. Scrofulous constitution. Has been an inordinate drinker. For fourteen months violent gastric pains after eating; nothing but milk tolerated, and frequently not that; vomiting of acid substances, and constant pituitous catarrh. Vomiting finally became incessant, and, when admitted, digestion seemed quite given out. April 5th, Dr. Debove resorted to *lavage*. Tepid water used, and Vichy afterward; the exit from the stomach followed of a considerable quantity of the detritus of food hardly attacked by the gastric juice, and having a bad odor. A demi-litre of milk introduced; this was well supported. April 6th, *lavage* and Vichy, followed by the introduction by the sound of fifty grammes of beef powder. During the day he drank two litres of milk. These brought on the pain in the evening; *lavage* resorted to and undigested liquid withdrawn. Half a litre of milk introduced by the sound; patient felt well for an hour, when pain set in, and at 5 A. M. there was an attack of intense pain, followed by vomiting. In view of this persistence of gastric pain following the *lavage* as ordinarily employed, Dr. Debove changed the treatment. Instead of two *lavages*, each followed by a repast, *lavage* and the sound were resorted to only mornings, a litre of milk and one hundred grammes of powder being given; and the stomach was emptied when the pains commenced. This modification was followed by excellent effects. *Lavage*, after pain, brought away foul undigested aliment. By April 28th he was given daily three litres of milk and three hundred grammes of the powder. May 29th, discharged cured. For full details of these two last cases, see "Progrès méd.," September 30, October 7, 14, and 21, 1882, where a fuller explanation of the theory and practice of *lavage* may be found.

In many cases in which the stomach does not digest, it is because it is embarrassed by irritating substances, the detritus of former repasts, which, accumulating and decomposing, interfere with the secretion of the gastric juice. In time, the changes and degenerations become permanent, and a cure is impossible; but, if these irritating substances be washed out, and certain aliments introduced, digestion becomes possible. Dr. Debove's method is usually to throw in a litre of simple water, followed by a litre of artificial Vichy. The tube of Faucher, modified by Debove, as heretofore described, is used, this acting as a siphon, and being free from many objections of the stomach-pump.

Since October 1, 1883, I have employed *poudre de viande*, both by direct alimentation and by the tube, in a considerable number of cases, in the majority of instances with

great benefit; and I herewith present some of the most striking.

VOMITING OF PREGNANCY.—Mrs. W., primipara, aged twenty-two, two and a half months pregnant; general health excellent. October 15th, had had for more than a month severe retching daily; impossible to retain any nourishment except a little dry bread or broiled ham, which produce acidity. These cases of uncontrollable anorexia and vomiting in pregnancy are too common to make it necessary to dilate upon the symptoms of this one. It is sufficient to say that none of the ordinary measures of treatment were of use, and it became evident that the patient would sink unless she could in some way be nourished, or premature labor be induced.

Injections of sanguis exsiccatus were used, also of Reed and Carnrick's peptones, but both had the effect of producing severe tormina. Tongue dry, and dry retching and vomiting of greenish mucus; great prostration; kidneys perfectly healthy.

November 15th, I obtained her consent to introduce Debove's tube, which I succeeded, fortunately, in doing without much difficulty. Ten grammes of the powder, prepared with the yolk of an egg and water, introduced; retained. Some crampy pains in the stomach. In the evening the same quantity, with a teaspoonful of milk and a little brandy to counteract the debility, was digested. The next morning, November 16th, there was less retching, and, at 8 A. M., twenty grammes with half a pint of milk given; retained; at 1 P. M., the same quantity; at 8 P. M., twenty grammes with half a pint of milk. November 17th, 8 A. M., twenty grammes with milk; retained; 12 M., twenty-five grammes given. Is obliged always to keep her bed, movement being followed by nausea and retching. A small piece of beef digested. Eight P. M., twenty-five grammes of the powder. This was followed by vomiting and two or three loose movements. November 18th, 8 A. M., no nausea. Twenty-five grammes with milk; rejected. At 11 A. M., took a mutton chop, and at 5 P. M. some rare beef and bread. November 19th, as the stomach was most sensitive mornings, and as she was now stronger, I deferred the use of the tube to 11.30 A. M. Thirty-seven grammes, however, introduced; retained. At 6 P. M., took soup and beef. November 20th, at 12 M., fifty grammes with milk and a little cognac; digested; took a very good dinner. Every day, until November 30th, the same plan was pursued. By this time the stomach had gained so much strength, and the gastric juice seemed to be so well secreted, that I determined to try to dispense with artificial alimentation. The next morning, at eleven, she was able to take a chop, and from this time the artificial alimentation was discontinued. I do not think it necessary to give here more than the outlines of the case; and would only state further that by the 20th of December she was able to take sufficient of ordinary food to maintain her strength and to go about the room. She is now, March 1st, quite free from nausea.

This is the only case in which I have known artificial alimentation by the sound employed in the vomiting of pregnancy. Whether it be likely to prove useful generally in these cases, remains yet to be seen. I can not, however, tell why it should not be, where the vomiting is idiopathic and not dependent on any disease of the kidneys or uterus, and I hope the experience of others will prove as favorable as my own, though I can not suppose it will in all cases.

ANOREXIA AND NAUSEA FROM MALARIAL POISONING.—J. S., a woman, aged thirty-three, fifteen years ago had bilious fever, and was salivated to such an extent as to cause all his teeth to fall out. Previously her constitution and health were unusual.

ly robust; since then they have never been perfectly normal. A transatlantic trip in the summer will keep her well until the next summer; but, without it, every winter and spring are characterized, particularly on the occurrence of warm, wet weather, by great physical depression, neuralgic headaches, fainting turns, nausea, and loss of flesh. In December, 1883, was confined to her bed for several weeks with these symptoms: anorexia, dry retching, and inability to contain any nourishment. Twenty-five grammes of the powder given with milk and a little whisky, and retained; the evening of the same day the dose was repeated. Next morning, thirty-seven grammes; well digested. This was given three times daily, and she soon became able to take other food; great improvement in strength. The attempt to increase the quantity to fifty grammes three times a day was followed by a violent fit of vomiting, and it became necessary to omit it for a day. It was then resumed in doses of thirty-seven grammes three times daily. Its use has been since continued regularly, about thirty-seven grammes being taken twice a day with other food; and the result has been a considerable increase of strength.

After the patient had commenced sitting up, a compound powder of another maker, which was highly vaunted, was administered; but it produced violent vomiting and purging. I do not give the name of the maker, as I do not wish to seem to disparage other fabrications.

I have observed equal benefit from the treatment in several other cases of anorexia, nausea, vomiting, and loss of strength, the result of malarial poisoning.

PHTHISIS PULMONALIS, DIRECT ALIMENTATION.—C. M., aged thirty-eight. Several members of this patient's family died of consumption. His own lungs became affected three years ago. I first saw him February 14, 1884. He had been confined to his bed for three weeks. Right lung dull at apex; left lung, principal lobe full of cavities; lower, infiltrated; numerous smaller cavities; profuse purulent expectoration; extreme debility; aphonia; evening temperature, average about 100.5°; morning, normal. I determined to employ the powder here, because I thought it would give him more strength. Dr. Charles McDowell undertook to superintend its administration, and it was given as follows:

	Powdered beef, 75 grammes.
February 16.....	100 "
" 17.....	150 "
" 18.....	175 "
" 19.....	175 "
" 20.....	187.5 "
" 21.....	187.5 "
" 22.....	187.5 "
" 23.....	187.5 "
" 25, died at 5.30 A. M.	

For several days there was quite an increase of strength, and the powder was taken without difficulty, and even relished.

PHTHISIS PULMONALIS, DIRECT ALIMENTATION.—R., aged thirty-two. Softening and râles all over left lung anteriorly; bronchial respiration; evening exacerbations of fever; night sweats; weight, 120 pounds; appetite and digestion good; naturally very healthy. Commenced giving powder in twenty-five-gramme doses before breakfast, and a similar quantity in the night, as he required nourishment then; well digested. The next morning and night gave thirty-seven and afterward fifty grammes. The morning dose was in time increased to seventy-five, and the evening to fifty. After the seventy-five grammes in the morning he felt no desire for other food till lunch. Three fourths of a pint of milk and two or three eggs were given with the dose of powder. The one hundred and twenty-five grammes

were equal to about sixteen ounces of beef, without fat or fiber. After two months of this treatment the weight was 132 pounds; the cough, sweats, and fever all diminished; the moist sounds have almost disappeared. Is in a fair way to recover, and has just started for the South to avoid the bad weather of March.

There were two favorable conditions for the improvement in this case—namely, the circumstance that there was no inherited disposition to consumption, the family being an exceptionally healthy one; and the fact that the patient was able to take this food in large quantities, together with other food, without inconvenience. Three or four teaspoonfuls of rum were added to each portion of the powder.

PHTHISIS PULMONALIS, DIRECT ALIMENTATION.—A young lady, aged nineteen. The mother died of consumption; has had since last spring a dry cough, with dyspnoea; pains in the chest; respiration of right side harsh and prolonged; bronchophony and slight dullness of percussion; menses absent for three months; emaciated. December 1st, commenced the administration of the powder. It has been well borne, and seventy-five to one hundred grammes daily have been taken with other food. March 1st, there had been considerable gain of strength, together with two pounds in weight. Menses come on every six weeks, though scanty; cough and pains are better. Other remedies, however, have been employed in addition to the powder.

PHTHISIS PULMONALIS.—A. R., a man in an advanced stage of phthisis. Night sweats, vomice, infiltration of both lungs, abundant expectoration, anorexia, and nausea. The patient has been greatly benefited by the powder, and has been able to take two hundred grammes daily with milk and whisky, the benefit consisting mostly in improvement in strength and diminished cough, sweating, and expectoration.

PHTHISIS PULMONALIS, ALIMENTATION BY THE TUBE.—A lady, aged forty-five. Diffused râles over both lungs; dullness of percussion in left lung anteriorly and posteriorly, and over right lung posteriorly; sweats; violent cough, and muco-purulent expectoration; great emaciation; intolerance of food; nausea and vomiting; great difficulty in retaining anything on the stomach. Had the powder prepared in various ways, but she could not take it, each attempt producing nausea or vomiting. I represented to her the advantages of super-alimentation by the tube, and she at last consented to permit me to use it. The first time, January 1st, I introduced twenty-five grammes, with milk, which was retained. The next day, the same amount twice. Four hundred grammes are now given daily, and the patient is gaining in weight. All her symptoms and physical conditions are better. She takes considerable other food, and her strength is increasing. The sound is introduced without difficulty by her nurse.

PHTHISIS PULMONALIS.—Mrs. B., aged fifty; parents consumptive, and cases of scrofula and cancer in the family. Pulmonary affection began in March, 1882. Admitted to the hospital December 6, 1883. Has profuse night sweats; evening temperature averages 101; dyspnoea; cough, with profuse muco-purulent expectoration; dullness marked in upper part of right lung with bronchophony; moist râles all over right lung; softening; moist râles in upper portion of left lung; is very weak; weight, January 6, 1884, eighty pounds. Commenced the use of the powder, giving it in milk with a little brandy. In thirty-eight days she took, on an average, thirty-eight grammes per diem, equal to five and a half ounces of beef. This was perfectly assimilated. The patient paid for a private room in the hospital, and could not be compelled to take the powder in as full doses as might have been tolerated—on some of the thirty-

eight days not taking it at all. Once or twice it produced vomiting. I represented to her the benefit to be derived from *garage*, and she consented to have it employed; but she found the introduction of the tube so unpleasant that I was obliged to desist. The principal objection she made to the powder was that it produced, all over, a sensation of intense heat, followed by sweating. This is a phenomenon generally to be expected, but after a time the sweating diminishes. In spite of the moderate amount of powder taken, a great deal of benefit was obtained. The cough, sweating, and expectoration diminished, the breathing became freer, and, on examining the chest, February 29th, I found almost complete absence of moist sounds. Her weight increased, while taking the powder, from eighty to eighty-one and a half pounds—not a large amount in itself, but important considering that her inherited tendencies were of the worst, that she was in an advanced stage of phthisis and was rapidly failing, and that she took only moderate quantities of the powder.

Dr. James W. Ward, the house physician of the hospital, notes down the following points of improvement which he observed:

- "1. Improvement of general strength.
- "2. Increase of weight.
- "3. Lungs have been less painful.
- "4. The sputa, which previously sank in water, now float.
- "5. The bowels, which were constipated, have become regular.
- "6. Appetite for other food, which was sadly depraved, has increased. Temperature has been lower since the use of the powder was commenced. In short, nutrition has been improved, and she has advanced in many ways."

I believe that, were I permitted to employ artificial alimentation in this case, I should bring about a very great amount of improvement in every way.

The intolerance to the powder, which is liable to occur after it has been taken for a few days, has already been mentioned; this may usually be overcome. The physician, however, must not pronounce against it, if it be at first repugnant to the patient or produce nausea or diarrhoea; his ingenuity in making it acceptable must be employed, the time of taking it, the dose, and the quantity of other food carefully regulated. In cases of organic disease of the stomach it has been found that it can be tolerated for a longer time and with less inconvenience than other articles of food. Not only is its digestibility marked in the stomach, but also in the intestines. The conclusions of Ama-nieux (*loc. cit.*) are:

1. That the direct administration of the powder never produces immediate revulsion of the digestive tube (vomiting or diarrhoea) *if the dose be not too large*, except where there is fever or some affection in its acute stage. This conclusion applies equally to direct and artificial alimentation.

2. That the stomach tolerates very well the powder of beef in suitable doses, according to the manner of administration, even if this organ be subject to functional disturbances or there be anorexia.

3. That it is well borne by the stomach under the same conditions; and

4 and 5. That the entire digestive tube tolerates it, even when it can bear no other food; and this is the only aliment that can be borne by subjects in the most advanced

stage of tuberculous and cancerous cachexia. My own experience has shown me, however, that an occasional case will be met with where its direct administration will not be well borne in sufficient doses to be of benefit. These are, however, rare.

According to the same author, the following phenomena are observed: Sensations of *bien-être*, slight elevation of the temperature, increase of sweating and perspiration, increase of appetite, digestion of food generally, phenomena of organic reparation, followed by diminution of sweats and expectoration. That these phenomena are observed as a rule is shown by this author from hospital records. A well-recognized fact by medical men, and formulated by Bécclard,* helps explain the return of the appetite, namely, "the removing of the need of food (appetite) is in relation to the activity or rapidity of the nutritive movement."

According to Debove, however, artificial alimentation shows that there is no relation between the appetite of patients and their digestive faculties. A patient, for instance, who loathes all food, will digest a large quantity readily when introduced by the sound. In other cases vomiting would occur, the patient suffering from actual hunger, masticating and swallowing with pleasure. In these cases, food introduced artificially would be retained.

Finally, it is not expected that the *poudre de viande* will prove a panacea; it will fail sometimes when skillfully used, directly, or by the sound, even where it seems in every way appropriate to the case.

While I do not advocate it as a perfect means of cure in cases where assimilation is mainly at fault, neither do I expect to see it relegated to the limbo of vaunted remedies and therapeutic agents which have been tried and found wanting. It has been used too thoroughly in crucial cases, by physicians deservedly eminent, to be any longer an assumed and theoretical system of treatment; and I have employed it myself with so much care and success as to feel assured that from it many cures are to be expected in cases where no room seems to exist but for discouragement and despair.

THE PATHOLOGY AND RADICAL CURE OF HAY FEVER, OR HAY ASTHMA.

BY JOHN O. ROE, M. D., ROCHESTER, N. Y.

FELLOW OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, MEMBER OF THE
MEDICAL SOCIETY OF THE STATE OF NEW YORK, OF THE AMERICAN MEDICAL ASSOCIATION, ETC.

(Second Article.)

(Concluded from page 495.)

In the treatment of hay fever we should first determine, by a careful exploration of the nasal chambers, the exact nature of the conditions which have been the exciting cause of the hyperæsthesia. Each particular spot which is especially sensitive should be located, and receive thorough and careful treatment until this sensitiveness is removed and no sensation of hay fever is experienced by the patient when these regions are touched. This hay-fever sensation is un-

* "Traité élémentaire de physiologie."

mistakable by the patient, for on touching these regions, however lightly, a burning sensation is felt in the nostril, as if the probe were heated, and is attended by the usual reflex phenomena.

When hypertrophied turbinated corpora cavernosa are the seat of the sensitive region, they should be thoroughly removed. When this region is the seat of the sensitiveness, though there is no well-marked hypertrophy of the turbinated bodies, sufficient tissue should be removed to destroy the diseased and sensitive terminal nerve filaments and to obliterate the enlarged blood-vessels. Redundant and hypertrophied tissue is best removed with Jarvis's snare, although caustics, such as acetic, chromic, or nitric acid, may be employed. For the destruction of the deeper plexuses of vessels, the galvanic cautery is by far the most efficient. It is also the most efficient means of removing the sensitive regions on the septum and other portions of the nasal chambers. For the latter purpose, a very small point should be used, so as to enable the operator to limit the cauterization entirely to the diseased tissue, and, by using a very small point, but little pain is occasioned.

All obstructions to the nostrils other than hypertrophic tissue should be removed, and also all abnormal conditions of the passages, whether they be sufficient to cause obstruction to the chambers or not, should be corrected.

In all these cases it is of special importance that there should be no points of contact between the turbinated bones themselves or the turbinated bones and the septum, even though there be no obstruction whatever to respiration. Spiculae of bone are often found projecting across like a spur and exciting irritation and producing thickening of the opposite surface. This condition is more often found between the middle and superior than the inferior turbinated bone and the septum.

Afterward, when all offending tissue has been removed, local medication should be made to the nasal passages until the parts are healed and the chronic rhinitis cured, and the special irritability and hyperæsthesia has disappeared from every portion that is shown by the exploration with a probe to be abnormally sensitive.

The time when these radically curative measures should be instituted is, my observations lead me to believe, when the patient is free from the affection, and in time to allow thorough healing of the parts before the time of the expected attack, although, if necessary, it may be begun during the attack.*

It is also advisable and even necessary (where there is a doubt as to the sufficiency of the treatment) to examine the patient from time to time during the hay-fever season to observe if any portion of the nasal mucous membrane be-

* Respecting the time that treatment is best undertaken, as Dr. Allen has anticipated ("Am. Jour. of the Med. Sci.," *loc. cit.*, p. 164, note), I can not quite agree with him that it is best instituted during the attack at the time when all the tissues are greatly swollen and inordinately sensitive.

Dr. Allen considers it preferable that it should be initiated at this time, for the reason that "the places of contact can be then easily determined." It will be at once seen that I have found this to be unnecessary, for the reason that all the sensitive regions can be accurately determined before in the manner already detailed above.

comes irritated that has before been overlooked. If so, it should then receive prompt attention, and the diseased portion be thoroughly removed.

The practical outcome or result of this method of dealing with hay fever is, after all, the most interesting evidence as to its value. Of the five cases which I reported to the society last year, four have been accessible, so that I have been able to determine the result in these.

CASE I.—A farmer, aged thirty-five years. Hay fever twelve years. Treated in the fall of 1878. Has remained entirely exempt from hay fever since—now five years.

CASE II.—I have lost sight of.

CASE III.—Mr. S., of Kansas, aged thirty-four. Hay fever twenty years. Was treated in mid-winter of 1881 and 1882. Has remained practically exempt. One hot, dry, dusty day last August he went out shooting in a dry stubble. Immediately after he had a profuse watery discharge from the nose, but which continued for only two or three hours. But he had no other trouble during the remainder of the season. This shows, however, that he has still some *slight* sensitiveness in the nose, for which he is to report for treatment early in the spring.

CASE IV.—Mrs. K., aged thirty-one years. Hay fever eight years. Treated in the spring of 1882. Has remained exempt since. Two summers have now passed.

CASE V.—Miss C., aged twenty-two, also hay fever eight years. Treated in the spring of 1882. Has remained exempt since. Last summer, however, about one week before the time for her annual attack, she took a severe cold, which rendered her nose and throat sensitive, so that on a dry, dusty day she felt a slight irritation about and had a slight watery discharge from the nose, but none of her old distressing symptoms of hay fever.

CASE VI.—J. R., aged twenty-seven, a stout, well-developed man, was referred to me March 9, 1883. He had had hay fever for eight years very severely, his attacks coming on about August 10th and continuing until frost came, and being attended with more or less asthma. During the remainder of the year he had more or less catarrh and frequent colds in the head, with marked stoppage of the nostrils. When free from colds, his nostrils were clear and unobstructed. The inhalation of dust or any marked irritant at any time would cause sneezing and temporary stoppage of them.

Examination showed moderate general thickening of the mucous membrane of both nasal passages, but the turbinated bodies were not noticeably hypertrophied, nor were there any bony obstructions. On exploration, marked sensitiveness was found all along the inferior and middle turbinated bones, especially at the posterior end, giving rise to the characteristic sensations of hay fever. A similar sensitive region was found along the lower portion of the septum on both sides, and on the left side it was also very sensitive along its upper portion.

Treatment.—The sensitive turbinated tissue was cauterized sufficiently to destroy the hyperæsthesia and to obliterate the enlarged vessels which the frequent, sudden, and great swelling of this tissue indicated to be the case. A very small point was used, so as to give the least amount of pain. The sensitive organs of the septum were also touched with the cautery-point. Afterward local treatment was continued to the passages for three or four weeks, until the parts had healed and no symptoms of hay fever could be excited in any portion of the nasal cavity.

He was traveling most of the time, and during the latter part of August went West. In November I heard from him that he had escaped entirely his annual attack, although he was in the region where others were having it and where he had had it before.

I will now add two equally interesting and very similar cases. In one of the patients the treatment was not sufficiently complete and thorough, and, in consequence, he had his annual attack. In the other, treatment was thoroughly followed out, and she was accordingly entirely cured.

CASE VII.—Mr. H., aged fifty-three, engineer. Hay fever very severely for twenty years, and attended with more or less asthma. His attacks came on from the 5th to the 15th of August and lasted until frost came.

During the remainder of the year he had more or less irritation about and discharge from the nose, which he attributed to the effect of hay fever. The slightest irritation would provoke sneezing, as sudden change of temperature from hot to cold, or cold to hot air. Spices, mustard, pepper, or horse-radish taken at meals would provoke violent attacks of sneezing, and dust was exceedingly irritating to him.

The summer of 1882 he spent in Florida to escape the disease. He went by water, and was entirely relieved as soon as he got well out to sea. While in Jacksonville he had but little trouble. He came home by rail the last of September, and by the time he reached Ohio he had hay fever even more severely than usual. June 18th of last year he came for treatment for hay fever. Examination showed marked hypertrophy of the inferior turbinated bones, a general disease and thickening and marked sensitiveness of the mucous membrane throughout the nasal passages.

I advised the removal of this hypertrophied tissue and all the sensitive areas in the nose, and afterward thorough general treatment to the other portions of the nose and throat.

I removed the tissue—a portion with the snare and a portion with the galvano-cautery. Before all the nasal disease was removed and the treatment of the case completed it was discontinued, and I did not again see him until the 18th of August, when he returned with hay fever very severely.

As I was about to leave for my vacation, I had no time to treat him then, and he went through with his severe annual attack. At the time of attack, when I saw him, there was no evidence of engorgement, swelling, and irritation of the tissues covering the inferior turbinated bones, on which I had operated for the removal of the hypertrophied tissues. On an examination of his nose, made a few days ago, I found the sensitive region to be confined mainly to the upper border of the septum on the right side. On touching this spot with a probe, asthma, violent sneezing, lachrymation, and a profuse watery discharge from the nose, were at once induced.

No special irritation was induced with the probe in other portions of the passages; not even a sneeze was excited.

CASE VIII.—Mrs. C., a distinguished music-teacher of Brockport and Rochester, consulted me, June 15, 1884, in regard to hay fever, from which she had suffered nearly every season since girlhood.

In describing her own case she says: "With my present knowledge of hay fever, I can see that I used to have it thirty years ago, but called it then a summer cold, and did not observe its seasonal periodicity closely. I remember, however, that a bouquet of roses was a terror to me, and a ride in the country during clover blossoming or harvest greatly aggravated this cold." She resided during this time in Brockport, N. Y., and afterward for two years in Washington, Ga. About 1868 she removed to Rochester, and escaped the fever four or five years. In 1876 she returned to Brockport, and found she had returned to her hay fever, which she observed came on from August 15th to 20th, and continued until frost killed vegetation. Some years she also had a severe attack of rose cold in June, which lasted six or eight days.

The symptoms attending her attack she described as fol-

lows: Itching of eyelids and back of the throat and mouth; complete closing of the nostrils, which would open only for the passage of drops or streams of hot, clear water. Unable to sleep with mouth open, and unable to breathe with it shut, she spent the night sitting upright in bed, she says, "wondering at what seemed to her the culpable indifference of physicians to a disease which produced such intense suffering."

Some nights she coughed almost incessantly—a dry, spasmodic cough, very much like a bark.

With the wear of the fever and loss of sleep, winter always found her weak and unable to resist the cold. Her throat was very sore most of the time, and, while she did not feel a constant catarrh, the least exposure gave her a severe cold in the head.

Her health became in consequence very greatly impaired.

Examination of her nose showed well-marked hypertrophy of the inferior turbinated bones, both anteriorly and posteriorly. The tissue covering the middle turbinated bones was also thickened, and the bones so markedly projecting as to be in contact with the septum. Limited regions of thickened tissue were also found on both sides of the septum, which were extremely sensitive to the touch of a probe. In fact, violent sneezing, etc., would be excited by touching almost any portion of the nasal cavity.

The treatment consisted in removing all the redundant hypertrophied tissue with the snare, and afterward the deep plexuses of vessels were destroyed with the galvano-cautery electrode. The sensitive tissue on the septum was also cauterized with an electrode having a very small point, so that only the diseased portions were touched, and but little pain was thereby occasioned.

The projecting portions of the middle turbinated bones were removed with a pair of bone scissors, under an anæsthetic.

After thus thoroughly removing all the tissue obstructions in the nose, mildly astringent local medication was continued until the parts were thoroughly healed and all abnormal sensitiveness of every portion of the passages, on being touched with a probe, had disappeared.

The result in this case was entirely satisfactory, as the little lady passed through the season without the slightest indications of hay fever.

In writing to an inquiring friend of hers—a hay-fever sufferer—on September 1st, she says:

"Up to August 20th I did not feel quite sure of my safety, as the vegetation was unusually late; but now the weeds are in their prime, and yesterday was a trial. I went on the lawn, took the mower from the gardener, and ran it in the hot sun; went into the garden and exercised violently; pulled weeds and nearly roasted myself, without a sneeze or a tear, and at night put my head on only an ordinary pillow and slept as well as if I had never had hay fever."

During the present winter she says she is stronger and her general health is better than it has been in fifteen years. She has also been entirely free from colds and sore throat, to which she was constantly subject before her treatment for hay fever.

In conclusion, gentlemen, it must appear to you that it is clearly demonstrable that the cause which annually inflicts so much suffering on so many individuals is to be found in the nasal chambers, and can, with care and patience on the part of the physician and perseverance on the part of the individual, be entirely removed; that in those cases in which we fail at first to give our patients entire relief we know that our work has been incomplete, and that, by perseverance, our efforts, in every instance, will be crowned with success.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 10, 1884.

THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

As was to be anticipated from the programmes, the meeting that was concluded at Washington yesterday brought out a considerable amount of interesting matter in the sections, including the addresses of the chairmen, notwithstanding the failure of the chairman of the section in surgery and anatomy to read his address. The first interest felt by the profession in these annual meetings, however, turns upon what is done in the general sessions. The President's address on this occasion was of the dignified and graceful character that everybody who knew Dr. Flint felt confident it would be. In the present state of feeling in the profession, its most important feature was, of course, the reference to the subject of the code of ethics. The President was almost constrained to make some mention of the matter, and we think he could scarcely have touched upon it more judiciously than he did. The action he suggested—the statement by a committee of the reasons why non-sectarian physicians feel a repugnance to affiliating with the partisans of any exclusive dogma in medicine—ought to prove of service, although much will depend on the way in which it is carried out. It would have been still better, perhaps, if the President's own charitable construction of the clause prohibiting consultations with irregular practitioners had been confirmed by explanatory resolutions passed by the meeting. Let it be understood that there are circumstances under which, as the President himself seems to think, the demands of humanity may take precedence of the written code, and we venture to say there will be no more discord on the ethical question. At all events, it is satisfactory to be able to record that the matter of ethics was not presented to the meeting in such a shape as to lead to anything approaching to controversy.

At almost every meeting of the association some endeavor is made to influence national legislation, and the meeting just closed was no exception. In the main, the measures urged upon the attention of Congress must be said to be such as commend themselves to every enlightened mind. The continuance of the committee charged with promoting legislation for the purpose of providing suitable quarters for the Army Medical Museum and the Library of the Surgeon General's Office was certainly most proper. Dr. Sternberg's resolutions calling upon the Government to make appropriations for the prosecution of researches relating to the causes and means of prevention of infectious diseases, and to make permanent details from the medical corps of the army and the navy of officers to conduct such investigations, are directed toward the accomplishment of a most worthy purpose; but, since they specifically call for the direction of the necessary expenditure to be intrusted to the

National Board of Health, they may not have the force with Congress which they might have had if they had been a trifle more general in their terms. The wording of one of the other resolutions seems to have been unfortunate, to say the least, for surely Congress is not likely to be persuaded of the temperateness of the association when it inveighs against "illegitimate" legislation.

We are surprised at the tenor of the minority report of the Board of Trustees of the Journal, but the fact of its having been tabled by a vote of more than two to one shows that the meeting took the view of the matter that we suggested last week it would have reason to take, namely, that the course of the journal had been eminently satisfactory. It is to be regretted that the distinguished editor of the journal still feels that he can serve in that capacity only for a brief period longer.

GIFTS TO MEDICAL COLLEGES.

It is commonly supposed that the rarity with which the beneficent direct their good works in a channel that makes them available for the furtherance of medical teaching springs from an apathy on the part of the public to the advancement of medicine. It is doubtless true that the contentions of the sects have done something to bring about such a feeling, but there seems reason to believe that the indifference of the community is more apparent than real. There is one consideration that appears adequate to explain the infrequency of gifts and bequests made specifically to medical schools, and that is the impression, which may be assumed to be common, that money given to a university will be partly applied to the purposes of the various departments of that university, including the medical school. Now, since almost every medical college is ostensibly a department of a university, it is quite intelligible that gifts to the parent institution should be considered sufficient to cover the needs of medical teaching. As a matter of fact, however, the connection between our medical schools and the universities of which they figure as departments is only nominal. It may not be the case, perhaps, that in no instance does the fund for the medical school benefit from the administration of the general fund, but certainly the cases must be very few in which it derives any such accession.

It ought not to be difficult to impress the importance of advanced medical education upon the community, and it seems as if that must have been accomplished long ago, but, perhaps for the reason we have suggested, it is among the greatest of rarities for it to result in any tangible benefit to the colleges. But it is encouraging to note that during the past few years the tide seems to have turned. Our readers have been made acquainted with the provisions for the Harvard Medical School and for the medical department of the University of Pennsylvania, as well as with the gratifying results that have attended the efforts of the Alumni Association of the College of Physicians and Surgeons, of New York, to raise a special fund for laboratory purposes. The most recent instance of the sort is the gift of the sum of fifty thousand dollars to the Bellevue Hospital Medical College by Mr. Andrew Carnegie, one of the trustees of the col-

lege. As the purposes to which, by the terms of the gift, the money can be applied are limited to the building and equipment of laboratories, it has devolved upon the faculty to raise a further sum with which to purchase the necessary land. The gift, therefore, is of no present pecuniary benefit to the faculty, but rather entails an additional outlay. To meet this increased demand, the faculty, we are glad to learn, has already met with such success that it has been enabled to secure a piece of land, fifty feet wide by one hundred and twenty feet deep, on Twenty-sixth Street, near First Avenue, on which it will soon build the necessary structures for complete laboratory facilities for the practical study of histology, physiology, pathology, and other branches. We understand that this will be the first considerable building in the country devoted wholly to such purposes. It is a pleasure to record this addition to the resources of the college, and we will add our belief that it will be administered to the greatest possible advantage.

NEWS ITEMS, ETC.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending May 6, 1884:

DISEASES.	Week ending April 29.		Week ending May 6.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	7	0	2	0
Typhoid Fever	8	4	12	5
Scarlet Fever	103	16	82	18
Cerebro-spinal meningitis	4	3	5	4
Measles	87	9	106	20
Diphtheria	41	16	39	24

YELLOW FEVER.—The United States steamer Portsmouth, with yellow-fever patients on board, arrived at Portsmouth, N. H., on Sunday, and anchored at the quarantine station in the lower harbor. Thirteen deaths are said to have occurred from the disease in Havana during the week ending Friday of last week.

SMALL-POX.—Five new cases of the disease are reported to have appeared in Ashland, Pa., on the 3d inst. Our London exchanges seem to consider an epidemic impending in Great Britain.

THE COLLEGE OF PHYSICIANS AND SURGEONS will hold its annual commencement Tuesday afternoon, the 13th inst., at Steinway Hall. The address to the graduating class will be delivered by the Rev. Howard Crosby, D. D.

DR. HAMMOND'S ARTICLE ON MERYACHIT, which originally appeared in this journal for February 16th, and the publication of which in the "British Medical Journal" for April 19th we alluded to last week, we now find in the "Union Médicale" for April 24th—*translated from an Italian journal.*

THE "PLANET."—We regret to have to announce that the publication of this monthly journal has been discontinued. The editor, Dr. C. E. Nelson, asks us to express his thanks to his late associates of the medical press for the courtesies they have extended to him, and we wish to add, for our own part, that we shall miss the piquant humor that was peculiar to the "Planet."

THE MASSACHUSETTS GENERAL HOSPITAL.—At a recent meeting of the trustees, the usual appointments were made of house officers (house physicians and surgeons, as they are called). One

of the candidates was supported by a report signed by four of the visiting surgeons, while the two other surgeons sent in a letter giving the reasons why they differed with their colleagues in regard to this appointment, which reasons the trustees must have regarded as cogent, for they appointed the candidate recommended by the minority. Soon after the appointment was announced, Dr. Henry J. Bigelow and Dr. Richard M. Hodges resigned their positions as surgeons to the hospital. The former gentleman was appointed surgeon in 1846, and the latter in 1863. We do not yet know what action the trustees will take in the matter, but it is to be hoped that the long and honorable terms of service of these two eminent surgeons may not thus be brought to an untimely close.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION will hold its sixth annual congress in New York on Monday, Tuesday, and Wednesday, May 12th, 13th, and 14th. The sessions will be held in the Hall of the Academy of Medicine, and the profession at large is invited to attend them. The following programme is announced: **MONDAY.**—*Morning Session, at 10 o'clock:* Roll-call, Reception of Guests, etc.; Address of Welcome, by the President, Dr. Francke H. Bosworth, of New York; The Clinical Significance of Fibrinous Exudations upon the Mucous Membrane of the Upper Air-passages, by the President; A Contribution to the Study of Congenital Syphilis, by Dr. John N. Mackenzie, of Baltimore; Appointment of Nominating and Auditing Committees; Election of Fellows. *Afternoon Session, at 3 o'clock:* Retro-pharyngeal Abscess, by Dr. John O. Roe, of Rochester; Congenital Web of the Vocal Bands (case), by Dr. T. A. DeBlois, of Boston; Gunshot Wound of the Larynx involving the Vocal Bands (case), by Dr. W. H. Daly, of Pittsburgh; A Case of Complete Paralysis of the Left Vocal Band, the result of an Incised Wound of the Neck, by Dr. J. Solis Cohen, of Philadelphia. *Evening:* Reception by the President, at 8 30 o'clock. **TUESDAY.**—*Morning Session, at 10 o'clock:* Business Meeting. At 11 o'clock: A Rare Form of Tumor (Cavernous Papilloma) of the Vocal Bands, by Dr. F. H. Hooper, of Boston; A Case of Echchondrosis of the Larynx, by Dr. Morris J. Asch, of New York; A New Method for the Removal of Laryngeal Growths, by Dr. W. C. Jarvis, of New York; Presentation of Instruments, etc. *Afternoon Session, at 3 o'clock:* Discussion of the New Nomenclature; Permanent Unilateral Paralysis of the Laryngeal Abductors, following Cerebral Hæmorrhage (unique case), by Dr. D. Bryson Delavan, of New York; Stricture of the Oesophagus (case), by Dr. Rufus P. Lincoln, of New York; Tracheal Stenosis, by Dr. E. Fletcher Ingals, of Chicago. *Evening:* Annual Dinner, at the University Club, at 7 o'clock. **WEDNESDAY.**—*Morning Session, at 10 o'clock:* Herpes Laryngis, by Dr. S. H. Chapman, of New Haven; Cases of Buccal Tuberculosis, by Dr. T. A. DeBlois, of Boston; Goitre, by Dr. William Porter, of St. Louis; On Hay Fever, and its Successful Treatment, by Dr. C. E. Sajous, of Philadelphia. *Afternoon Session, at 3 o'clock:* Spasm of the Glottis, by Dr. Louis Elsborg, of New York; A Contribution to the Study of Laryngeal Chorea, by Dr. Edgar Holden, of Newark; On the Comparative Value of the Galvano-Cantery in Diseases of the Nasal and Pharyngeal Cavities, by Dr. E. L. Shurley, of Detroit; A Contribution to the Study of Adenoid Vegetations at the Vault of the Pharynx, by Dr. Beverley Robinson, of New York; Election of Officers, and their Induction into Office.

PROFESSOR GOSSELIN, according to the "Lancet," is at Cannes, in a state of health that, taken in connection with his age, occasions some anxiety.

THE HUDSON COUNTY, N. J., MEDICAL SOCIETY.—At the annual meeting of the District Medical Society for the County of Hudson, held at Jersey City, May 6th, the following-named

gentlemen were elected officers for the ensuing year: Dr. William Perry Watson, president; Dr. James A. Exton, vice-president; Dr. Calvin F. Kyte, secretary; Dr. G. Fred. Pitta, treasurer; Dr. Charles G. Schubt, reporter; Dr. Exton, Dr. Gordon, Dr. Helfer, Dr. Hoffman, Dr. Kyte, Dr. Schubt, and Dr. Watson, delegates to the next meeting of the State Medical Society, to be held at Cape May, June 14th.

NIAGARA UNIVERSITY.—The power of the university to confer the degree in medicine having been called in question, as we stated some weeks ago, a bill has passed the Legislature, and been signed by the Governor, specifically giving the corporation that power. The bill provides that candidates for the degree must have attended three courses of lectures, which provision, as we understand that the bill was drawn in accordance with the wish of the university, is a substantial sign of the desire of the faculty to raise the standard of medical education.

SUICIDE OF A PHYSICIAN.—Dr. Edward Seigle, of Newton, N. C., is reported to have committed suicide last Sunday, by taking laudanum.

THE LATE DR. WILLARD PARKER.—The Board of Health of the City of New York has passed resolutions of regret for the death of Dr. Parker, who was a member of the first board of health of the city.

THE NEW YORK ACADEMY OF MEDICINE.—At the next meeting, to be held Thursday evening, the 15th inst., the following papers will be read: "Practical Suggestions upon the Alimention of Patients suffering from Dysphagia," by Dr. D. Bryson Delavan; "On Chance of the Tonsils," by Dr. Robert W. Taylor.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from April 27, 1884, to May 3, 1884:*

HEGER, ANTHONY, Major and Surgeon. From Department of Texas to Department of the East. Par. 2, S. O. 101, A. G. O., May 1, 1884.

HAPPERSETT, J. C. G., Major and Surgeon. From Department of Texas to Department of the East. Par. 2, S. O. 101, A. G. O., May 1, 1884.

BENTLEY, EDWIN, Major and Surgeon. From Department of the East to Department of Texas. Par. 2, S. O. 101, A. G. O., May 1, 1884.

MIDDLETON, PASSMORE, Captain and Assistant Surgeon. From Department of Texas to Department of the Missouri. Par. 2, S. O. 101, A. G. O., May 1, 1884.

KOERPER, E. A., Captain and Assistant Surgeon. From Department of the East to Department of Dakota. Par. 2, S. O. 101, A. G. O., May 1, 1884.

DICKSON, J. M., Captain and Assistant Surgeon. From Department of the East to Department of California. Par. 2, S. O. 101, A. G. O., May 1, 1884.

GIRARD, A. C., Captain and Assistant Surgeon. From Department of Dakota to Department of the Missouri. Par. 2, S. O. 101, A. G. O., May 1, 1884.

GIRARD, J. B., Captain and Assistant Surgeon. From Department of Arizona to Department of the East. Par. 2, S. O. 101, A. G. O., May 1, 1884.

HALL, J. D., Captain and Assistant Surgeon. From Department of Dakota to Department of the Columbia. Par. 2, S. O. 101, A. G. O., May 1, 1884.

HALL, WILLIAM R., Captain and Assistant Surgeon. From Department of the Missouri to Department of Texas. Par. 2, S. O. 101, A. G. O., May 1, 1884.

CUNNINGHAM, T. A., Captain and Assistant Surgeon. From

Department of the East to Department of the Missouri. Par. 2, S. O. 101, A. G. O., May 1, 1884.

MCONEERY, GEORGE, First Lieutenant and Assistant Surgeon. From Department of Arizona to Department of Dakota. Par. 2, S. O. 101, A. G. O., May 1, 1884.

COCHRAN, J. J., First Lieutenant and Assistant Surgeon. From Department of the Missouri to Department of Arizona. Par. 2, S. O. 101, A. G. O., May 1, 1884.

SCHUFFELDT, ROBERT W., Captain and Assistant Surgeon. Relieved from temporary duty in Surgeon-General's office and ordered to report to Lieutenant-Colonel Basil Norris, Surgeon, U. S. Army, attending surgeon, Washington, D. C., for temporary duty in his office. Par. 6, S. O. 100, A. G. O., April 30, 1884.

BARROWS, C. C., First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Grant, A. T., and ordered to report for duty at Whipple Barracks, A. T., relieving First Lieutenant W. E. Hopkins, Assistant Surgeon, who, upon being relieved, will report for duty as post surgeon at Fort Grant, A. T. Par. 1, S. O. 31, Headquarters Department of Arizona, April 21, 1884.

PHILLIPS, JOHN L., First Lieutenant and Assistant Surgeon, Fort Warren, Mass. Ordered to report for temporary duty to the commanding officer at Fort Preble, Maine. Par. 1, S. O. 81, Headquarters Department of the East, April 28, 1884.

CUTLER, JOHN M., Colonel and Surgeon. Retired. Died at Morristown, N. J., April 26, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending May 3, 1884:*

HARVEY, H. P., Passed Assistant Surgeon. Detached from Naval Hospital, Chelsea, and ordered to the St. Mary's.

MC CARTHY, R. H., Passed Assistant Surgeon. Ordered to Naval Hospital, Chelsea.

WAGGENER, J. R., Passed Assistant Surgeon. Detached from the St. Mary's and ordered to the Hartford.

WISE, J. C., Surgeon. Detached from the New Hampshire and ordered as member of Board of Examiners at Annapolis.

CRAIG, T. C., Assistant Surgeon. Promoted to Passed Assistant Surgeon.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, May 12th:* New York Ophthalmological Society (private); New York Medico-Historical Society (private); New York Academy of Sciences (Section in Chemistry and Technology).

Tuesday, May 13th: New York Surgical Society; New York Medical Union (private); Medical Societies of the Counties of Albany (semi-annual), Greene (annual), Rensselaer, and Ulster, N. Y., and Camden (annual), Morris (annual), and Sussex, N. J., Newark Medical Association (private); Jersey City Pathological Society (private); Trenton, N. J., Medical Association (private).

Wednesday, May 14th: New York Pathological Society; American Microscopical Society of the City of New York; New York Medico-Legal Society.

Thursday, May 15th: New York Academy of Medicine.

OBITUARY NOTES.

PROFESSOR SAMUEL D. GROSS, OF PHILADELPHIA.—In our last issue we stated that Professor Gross's condition was such as to give occasion for anxiety. He had been ill for a number of weeks, and on Tuesday, the 6th inst., he died. It is understood that his remains were disposed of by incineration.

Samuel D. Gross, M. D., LL. D., D. C. L., emeritus professor of the institutes and practice of surgery in the Jefferson Medical College, was born near Easton, Pa., July 8, 1805. After a high-school education, he studied medicine as a pupil of the late Dr. George McClellan, and received the degree in medicine from

the Jefferson Medical College in 1828. He began practice in Philadelphia, but returned to Easton in 1830. In 1833 he removed to Cincinnati, having been made demonstrator of anatomy in the Medical College of Ohio. In 1835 he became professor of pathological anatomy in the medical department of the Cincinnati College. During his stay in Cincinnati he earned a wide reputation as a surgeon and as a contributor to the advancement of medicine. In 1839 he was made professor of surgery in the University of Louisville, where his fame soon became national. In 1850 he came to New York, having been appointed to the chair of surgery in the medical department of the University of the City of New York, as the successor of Dr. Valentine Mott. He served but one season in this capacity, however, and returned to Louisville in 1851. In 1856 he was chosen professor of surgery in the Jefferson Medical College, succeeding Dr. Mütter, and he remained in Philadelphia thereafter.

During the early part of his career as a teacher, Dr. Gross was chiefly known to the profession throughout the country as the author of a systematic treatise on pathological anatomy which was for many years the standard text-book in America. In 1859 the first edition of his "System of Surgery," a colossal and monumental work, was published. This book at once took a prominent place in the surgical literature of the world, and, perhaps more than any other single work ever issued from the American press, served to disclose the achievements of the American profession to their colleagues in foreign countries. Ever since it appeared it has been everywhere considered as among the best treatises on the subject. Dr. Gross was the author of several other works, all of which bore evidence of excellence, and at one time he was the editor of the "North American Medico-Chirurgical Review." He was the first president of the Philadelphia Pathological Society, of which he was one of the founders, and at different times he was president of the American Medical Association, of the Pennsylvania State Medical Society, of the International Medical Congress, and of the American Surgical Association. He received distinguished honors from a number of foreign universities, including the degree of D. C. L. from Oxford and that of LL. D. from Cambridge and Edinburgh, the degree from the latter university having been conferred upon him *in absentia* at the tercentenary festival.

In addition to these formal honors, Dr. Gross was held in heartfelt admiration and esteem by the great mass of the profession in the United States, of which there could be no more touching mark than the action of the American Medical Association at the meeting held this week in Washington, as will be found reported in another column. Few men ever lived who bore greater sway over the medical profession than Dr. Gross has borne for many years past, and his influence was due to no art, but to the simple power of a long course of devotion to the best interests of those who delighted to do him honor. The world is better for his having lived, and no one will read the announcement of his death without a feeling of sadness. There is something touching in the fact that Dr. Gross and Dr. Willard Parker, who were closely associated in their early life, have paid the debt of nature within a few days of each other.

DR. A. RANDOLPH MOTT, JR.—Dr. Mott, a graduate of the University of Virginia, in the class of 1878, died on Tuesday, the 6th inst., of typhus contracted in the line of his duty as a member of the house staff of the Riverside Hospital, in this city, where he had served with conspicuous ability and devotion under the direction of the Board of Health. His untimely death adds another to the many instances of the self-sacrifice of physicians for the good of their fellow-men. The Board of Health has passed resolutions of regret for his decease, and of sympathy for his kindred.

Letters to the Editor.

THE NEW YORK SKIN AND CANCER HOSPITAL.

To the Editor of the New York Medical Journal:

SIR: As the impression seems to be more or less prevalent that the New York Skin and Cancer Hospital has abandoned the care of cancer, we deem it desirable to have the error corrected. The aim of the institution from the first has been to undertake the study and treatment of this disease, and over one third of the beds have, from the opening of the present building, been set apart for this purpose.

A tract of land of nearly one hundred and fifty acres has recently been secured just beyond the city line, and the plans for cottage pavilions have already been drawn. It is proposed to erect some of these at once, and to add to the number as they may be required, so as to afford unlimited accommodations for each and every case of cancer requiring assistance. Both early cases for operation are received and those which are chronic and hopeless.

Our city hospital, No. 243 East Thirty-fourth Street, will still be continued, and clinics are held there as follows:

Skin clinics every afternoon from two to four o'clock.

Special clinics for cancer every Monday, Tuesday, Friday, and Saturday, at the same hour.

L. D. BULKLEY, M.D.,
GEORGE HENRY FOX, M.D.
J. E. JANVIER, M.D.,
R. F. WEIR, M.D.,
E. L. KEYES, M.D.

Proceedings of Societies.

AMERICAN MEDICAL ASSOCIATION.

Thirty-fifth Annual Meeting, held in Washington, Tuesday, Wednesday, Thursday, and Friday, May 6, 7, 8, and 9, 1884.

Tuesday—First Day.

The meeting was called to order in the Congregational Church, at the corner of Tenth and G Streets, at 10.30 A. M., by the chairman of the Committee of Arrangements, Dr. A. Y. P. GARNETT. After a prayer by the Rev. WILLIAM A. LEONARD, the chairman introduced the President of the Association, Dr. AUSTIN FLINT, of New York.

AN ADDRESS OF WELCOME was then read by Dr. GARNETT, after which he announced the following

LIST OF ENTERTAINMENTS.—*Tuesday:* Reception by the President of the United States, at the Executive Mansion, from 8.30 to 10.30 P. M.; Reception by Mr. and Mrs. L. Z. Leiter, from 9 to 11 P. M. *Wednesday:* Reception and Entertainment by the Medical Profession of Washington, at the National Rifles' Armory, from 9 to 12 P. M. *Thursday:* Illumination of the Corcoran Art Gallery, and Reception by Mr. W. W. Corcoran and the Board of Trustees, from 8 to 10 P. M.; Reception by Commissioner and Mrs. Loring, from 9 to 11 P. M.; Reception by Mr. and Mrs. W. T. Hildrup, from 9 to 11 P. M.; Reception by Chief Justice Morrison R. Waite, from 9 to 11 P. M. *Friday:* Reception by the Surgeon General of the Army and his Staff, at the Army Medical Museum, from 8 to 11 P. M.; Reception by the Hon. George F. Edmunds, President *pro tempore* of the Senate, and the Hon. John G. Carlisle, Speaker of the House of

Representatives, at 8 P. M.; Illumination of the Capitol from 8 to 10 P. M.

COMMUNICATIONS were acknowledged by the Committee of Arrangements from A. Pearce Gould, F. R. C. S., of London, and from other eminent medical men of Europe, and were ordered on the minutes.

THE REGISTRATION.—The secretary read the list of registered delegates up to the time of the morning session having been called to order, the whole number being five hundred and ninety. On registering, each delegate had subscribed to the following declaration: "In acknowledgment of having adopted the constitution, by-laws, and code of ethics of this body, and of my willingness to abide by them, and use my endeavors to carry into effect the objects of this association, I hereunto affix my name."

INVITED GUESTS.—Dr. J. H. TURNBULL, Dr. JONAS A. MARSHALL, Dr. GORLET, and the members of the Medical Association of the District of Columbia were invited to seats in the meeting.

A LETTER FROM DR. JOHN L. ATLEE, an ex-president of the association, expressing his regret at being unable to attend the meeting, was read by the secretary and ordered on the minutes.

THE PRESIDENT'S ADDRESS.—The President, Dr. AUSTIN FLINT, of New York, then proceeded to read his address, in which he referred to the natal period of the existence of the American Medical Association, and considered the reasons why it was founded and the reasons for its continued existence. He quoted from certain chapters setting forth the objects of the association, and then dwelt at more or less length upon each of them respectively. In proof of the progress of medicine, he pointed to the part recently shown to be played by germs in the production of disease, and, quoting from an address of Professor Huxley's, said he would so alter the author's statement as to read: It is to be hoped that means will be found to destroy morbid agents outside the body, thereby securing prevention of disease, and that a means will be found to effect a destruction of these agents within the body, thereby arresting the course of disease.

With regard to the elevation of the standard of medical education, he thought more had been done than seemed commonly to be supposed, and quoted from the work done and the recommendations made at different times by the committee on this subject. The President spoke of the importance of a closer union of didactic with clinical teaching, of increased demonstrative instruction in certain branches of medicine—such as histology, the physical exploration of the lungs, heart, etc.—and of allowing more time for oral recitations. One of the most important matters in attempts to elevate the standard of medical education related to the preliminary requisites for entering upon the study of medicine. Among the requisites which had been recommended was some knowledge of Latin and Greek, and the President thought that no exception could be taken to such a recommendation as it related to medicine; but, if one were about to enter upon the study of arts, or certain other educational courses, he thought the time spent in learning Greek and Latin might better be devoted to French and German. The practical question was, he repeated, What could the association do toward advancing the medical profession, and, before replying, he thought it would be proper to speak of what it was best not to do. It was not desirable to depreciate medical education in this country as compared with medical teaching and professional standing in other countries. As to the manner of medical instruction, he thought it more practical in many respects in this country than in Europe. Sweeping charges of venality and incompetency against medical schools were also improper. There was but little ground for the accusation that medical colleges resorted

to disreputable means for obtaining students. There were advantages and disadvantages connected with the necessity for self-support on the part of medical colleges.

Some of the evils complained of might be obviated by unity of action on the part of the medical profession throughout the country. Suppose that private preceptors recommended their pupils only to responsible schools, and that physicians received as pupils only those who, before entering upon the collegiate course, had received proper preliminary education. Let the National Association take the initiative step, and let it and local and State societies work together and obtain uniform action in bringing about an improvement in medical education. But it should not be expected that all desired improvements could be effected at once. Dr. Flint briefly referred to the subject of boards of medical examiners, and, without discussing their advantages or disadvantages in full, pointed out a few of the intrinsic objections to them.

With regard to the third object of the association, the promotion of the usefulness, the honor, the interests, etc., of the medical profession, he would confine his remarks to medical ethics. He spoke of the good influence which the code had had upon the minds of the profession, and quoted from the addresses of several of the ex-presidents. The Medical Society of the State of New York had taken precipitate action in changing its code of ethics, the portion of the national code which had been specially objected to relating to consultations with irregular practitioners. The interpretation of certain parts of the code at different periods seemed to vary more or less, although its intrinsic moral worth ever remained the same. With regard to the meaning of the term irregular practitioner, Dr. Flint thought it should not be interpreted to mean one who might entertain exclusive ideas regarding certain matters in medicine, but rather one who adopted a sectarian name, as homeopath, eclectic, etc. It might prove hazardous to tamper with the code of ethics; but he thought it proper, with the advance of time, to make interpretations of that code as it now stood. He would submit as a recommendation that the association adopt resolutions embodying a more precise specification than the code furnished as to the grounds for excluding consultations with irregular practitioners, and he would approve of its being stated that those who adopted a sectarian name should be excluded from fellowship with the regular profession. As to that object of the association relating to the means for directing public opinion with regard to the profession, etc., let it be understood that there could be no antagonism between "humanity" and medical ethics.

He recommended that the members take special interest in the sectional work, and also spoke of the advantages of the social features of the meetings. In this connection he recommended that steps be taken to have the International Medical Congress meet in this country in 1887. This recommendation had also been suggested or concurred in in letters which he had received from several gentlemen, among others Professor Samuel D. Gross, of Philadelphia, who was prevented from attending the meeting on account of serious illness. Dr. Flint took occasion here to pay a graceful tribute to this eminent surgeon.

Dr. KINLOCK being in the chair, Dr. TOXEZ, of Washington, moved that a vote of thanks be tendered the President for his able address, and that it be requested for publication. Carried.

PROFESSOR SAMUEL D. GROSS.—Dr. TOXEZ also offered the following resolution:

Whereas, It has come to the knowledge of the American Medical Association that one of its former presidents, a surgeon of world-wide reputation, whom we miss at this meeting, is confined to his home by serious illness; therefore be it

Resolved, That the American Medical Association tenders Professor Gross its heart-felt sympathy in his sufferings, and

expresses its sincere hope for his speedy recovery, and for many years of continued usefulness in the profession he has so signally adorned. The resolution was adopted.

Dr. GIRON, of the navy, moved that that portion of the President's address referring to Professor Gross be telegraphed to him at once as an appropriate form of expression of the sentiments of the association. Carried.

Dr. RICHARDSON stated that he had only recently come from the bedside of Dr. Gross, who, when asked whether he had any word to send the association, said, in a feeble voice, "Give them my love."

On motion of Dr. SAYRE, the resolutions offered by Dr. Toner were ordered to be telegraphed to Dr. Gross. And it was further resolved that the expression of love on the part of Dr. Gross toward the association be acknowledged and reciprocated.

The secretary read a telegram from Dr. BALDWIN, of Alabama, regretting his inability, on account of illness, to be present at the meeting.

Dr. SAYRE moved that that portion of the President's address requesting that the International Medical Congress meet in this country in 1887 be referred to a special committee of five, of which Dr. Billings should be the chairman. Carried.

MEDICAL ETHICS.—Several resolutions were offered regarding that portion of the President's address relating to medical ethics, for which the following, by Dr. FERGUSON, of New York, was finally substituted:.

Resolved, That that portion of the President's address referring to the subject of medical ethics be referred to a committee of seven, to report upon the recommendations therein contained as speedily as possible. Adopted.

The titles of several papers not on the printed list were then read, and, on motion, they were referred for reading before the appropriate sections.

Certain other gentlemen were invited to seats in the meeting and the session was then adjourned for the day.

Wednesday—Second Day.

The meeting was called to order at 10 A. M., by the President. A prayer was offered by the Rev. W. A. Bartlett, D. D.

THE DEATH OF PROFESSOR GROSS.—The President formally announced the death of Professor Samuel D. Gross, of Philadelphia, and appointed the following committee to take such action as it might think proper in the matter: Dr. Richardson, of Louisiana; Dr. Sayre, of New York; Dr. Packard, of Pennsylvania; Dr. Hamilton, of New York; Dr. Gunn, of Illinois; Dr. Briggs, of Tennessee; and Dr. Hays, of Pennsylvania. On motion, the President of the association was added to the committee as its chairman. The secretary read a dispatch from Dr. Samuel W. Gross, thanking the association for its telegraphic message expressing sympathy, but stating that it had not been received until after his father's death. Dr. Gross's dispatch was ordered on the minutes.

THE COMMITTEES ON THE PRESIDENT'S ADDRESS.—After some announcements by the Committee of Arrangements, the President appointed the following general committee on his annual address: Dr. N. S. Davis, Dr. W. W. Dawson, Dr. W. T. Briggs, Dr. T. S. Prout, Dr. Starmont, and Dr. H. B. Ransom. As the special committee, he named the following gentlemen: Dr. J. S. Billings, Dr. L. A. Sayre, Dr. R. H. Fitz, Dr. I. M. Hays, and Dr. H. F. Campbell.

MEDICAL SERVICE ON SHIPBOARD.—The committee appointed to frame resolutions in favor of securing more competent medical and sanitary service on board trans-oceanic passenger vessels reported, through its chairman, Dr. A. N. BELL, of New York, that a bill had been prepared and presented to Congress which covered the matter. [The full text of the bill has already been

published in this journal.] Dr. Bell went on to state that the mortality on board emigrant ships entering the port of New York for four years, up to 1883, was 35-12 in a thousand, being considerably greater than for a like period ending in 1873. This death-rate was at least three times as great as it ought to be. The causes of death were largely negligence and filth.

Dr. KEYSER, of Pennsylvania, said the bill before Congress was excellent, so far as it went, but it did not go far enough; it provided that the ship's surgeon might report to the captain, and the captain to the company—but to whom was the company to report? The bill should require the surgeon to report directly to the United States Government.

Dr. IRWIN, an English physician, thought the object of the bill was excellent, but that it was impracticable as it stood, and would prove ineffectual. He suggested certain points of improvement.

On motion, the report was received, and the committee continued, the suggestion having been made that information in regard to the matter be reduced to writing and submitted to the committee.

Dr. PRATT, of Michigan, moved the following resolution, which was carried unanimously:

Resolved, That the American Medical Association, now in session, urge upon Congress the necessity of suitable and efficient legislation to promote the well-being of immigrants to this country, and to protect our public health.

THE ADDRESS IN MEDICINE.—The chairman of the section, Dr. JOHN V. SHOEMAKER, of Philadelphia, then read his address.

After a few preliminary remarks on the difficulty of his subject, in consequence of the new theories constantly advanced, he said that in the field of pathology and pathological research the study of the infinitesimal had attracted great attention; and of the subjects prominently brought to the attention of the profession and exciting universal interest, more than any other, was that of the bacillus theory and the contagious character of tuberculosis. While the presence of micro-organisms in other diseases was being investigated and studied extensively, there was none which had so great a bearing and had caused so much comment as this one. Only a few years ago Koch stood almost alone in its advocacy. Now there were numbers of unbiased observers who confirmed his famous discovery. Foremost among these was Watson Cheyne, who visited Koch's laboratory for the express purpose of investigating the subject. His report fully confirmed the facts set forth by the great investigator, besides demonstrating the constant occurrence of the bacillus in all tubercular structures, as well as the relative position of the parasitic organism to cell-structure. Similar confirmatory evidence had been produced by Prudden, Dreschfeld, West, Gibbs, Heron, Wipham, Meissen, and others, from a clinical view of the constant presence of the bacillus in the sputa of phthisis; while Charnley Smith had even ingeniously demonstrated its presence in the expiratory air of consumptives by filtering it through gun-cotton, dissolving the latter in ether, and then fixing it on microscopical slides for inspection.

Dr. Austin Flint, Sr., accepted the new theory as well as the ætiological character of this micro-organism when added to predisposition, leaving the subject of contagion dependent upon the causative element combined with the favorable soil for its propagation, ascribing the usual absence of contagion to a lack of predisposition; and considered the presence of the bacillus as one of the most essential elements for the diagnosis of phthisis. Dr. Janeway, Dr. Welch, and Dr. Peabody, well-known authorities on this subject, concurred with Dr. Flint; likewise Dr. H. C. Ernst, in his contribution presented to the Massachusetts Medical Society, besides numerous other investigators, both here and abroad.

The presence of the bacillus had been observed in other tubercular lesions than those of the lungs: as in the mouth and soft palate, by Guttman and Finger; in the skin by Cornil; in lupus by Demme; in the uterus by Lindsey Stephens; in the urinary tract by Rosenstein, Babés, and Cornil, as well as in rectal abscesses by Smith. Dr. Wilson Fox admitted the fallacy of his former experiments, and accepted the theory of the contagious character and inoculability of the virus, admitting that injury to the rodents was not followed by tuberculosis, as previously expressed by him.

Now, while the adherents to Koch's theory had increased wonderfully, there were not wanting those who were open in their criticism, and opposed to the acceptance of anything like a bacterian origin of tuberculosis or other diseases. Their opposition was not based merely upon assertions or clinical evidence, but the result of years of observation and experiments, conducted here as well as at the very birthplace of the bacillus theory. Among those most prominently arrayed against it were Spina, Finkler, and Eichler, who pronounced the staining methods of Koch fallacious and misleading, while Feltz admitted his failure with cultivation by following Koch's method.

Formad, in this country, had made a most vigorous attack upon it, and had referred the etiology of tuberculosis to histological changes rather than to parasitic invasion, in which deduction he was supported by many eminent pathologists, such as Longstrech and others. In his denial of the contagiousness of tuberculosis he was in accord with Virchow, von Recklinghausen, Stricker, Gull, Williams, Watson, Paget, Humphrey, Richardson, Bennet, Hiram Corson, Trail Green, N. S. Davis, H. F. Campbell, and others.

The speaker then proceeded to say that the bacillus tuberculosis theory, however, was not the only one that had excited attention. The bacterial origin of other diseases had been earnestly advocated as well. Thus, a micro-organism had been found and studied by Friedländer as a micrococcus of pneumonia; and he thought it might serve to explain the occasional epidemic form of that complaint in certain localities. He also mentioned numerous other diseases in which these micro-organisms had been discovered, according to Koch special honor for his skill in this field of research.

Referring to the subject of medicine, he said our knowledge of nervous affections, though it had not progressed with the giant strides of other branches of medicine, was steadily advancing and emerging from its mysterious enfoldings. The localization of cerebral functions, though now generally accepted, had advanced us practically but little, though the trephine had daringly opened to the neurologist the hidden regions of dura mater and gray matter. Locomotor ataxia presented in its chronic state three diagnostic points for distinction: that of Duchenne; another depending on diffuse sclerosis of the cord and medulla oblongata; and a third was made of the ataxia of the periphery.

Speaking of typhoid fever, he inferred that the treatment by cold baths, of all antipyretics, was now thought to be the most serviceable, if we could trust to the statistics of recent investigators, as well as the thorough researches of Sassetzky in the analyses of the excreta. Alluding to renal diseases, he asserted that albuminuria had long been the subject of scientific inquiry, being considered more and more of nerve origin. Its close relation to diabetes, with mutual interchange in certain affections, had brought forward the proposition that both albuminuria and glycosuria might be produced by irritation of certain parts of the floor of the fourth ventricle. The hypertrophy of the muscular coat of the arterioles and the increased tension of the vascular system were also asserted to be due to irritation of the vaso-motor centers of the medulla. The latter, espe-

cially, had proved valuable in modifying the treatment of albuminuria. That the toxic influence of certain substances, as well as severe febrile affections, was productive of albuminuria was well known, and a recent instance had been cited where it occurred after varicella. Peptonuria had been investigated and found to co-exist with suppuration from various causes, or with large exudations. Speaking of the disease known as actinomycosis, and as being peculiar to horses and cattle, he stated that it had been exhibited by Treves in a man whom he brought before the London Pathological Society. All stages of the disease, from minute solid growths to large suppurating and sloughing masses, were present.

He thought it necessary, in consequence of the grave accusation cast against American pork by some of the European authorities, that he should say a few words upon the subject. He said that trichiniasis was with us a very rare disease indeed, in comparison with its frequent occurrence in continental Europe. In spite of the prohibitive edict against our pork in Germany, quite an endemic of trichiniasis had prevailed there of late. As there had been isolated cases reported with us, he would refrain from any attempt at defense, but would simply remark that the mortality from trichiniasis in this country, in comparison with Germany, would lead us most certainly to discriminate in favor of our product to that of the foreign—even if we did not attribute our comparative immunity to the more civilized manner in which we partook of it than the semi-barbarous fashion of eating it uncooked. French physicians, in the Academy of Medicine, of Paris, had already given their opinion that American pork was not so dangerous as the trichinophobist would have us believe, and recommended that the prohibition of its importation be removed.

As to therapeutics, while in past years it had been ignored to a great extent by many physicians and scientists, it had undoubtedly now assumed new features entitling it to a prominent position. He gave a list of some of the chief remedies which had found approval during the past year, such as kairine among the antipyretics; paraldehyde; the *Abrus precatorius*, the jequirity bean of Brazil; the salts of nickel, and especially its bromide; bismuth salicylate; nitro-glycerin; the chloride of gold and sodium, etc.; in connection with them mentioning the diseases to which they were applicable. Treating of antiseptic inhalations, he thought that the vast research in the field for micro-organisms as causative elements of disease, and the discoveries made therein, had given a new impetus to antiseptic treatment in every branch. Antiseptic inhalations for pulmonary disease had proved of value, whether the germ theory was sustained or not.

In concluding his address he directed the attention of those entering the profession to the necessity of thoroughly mastering the details of all its different branches; above all, that of general medicine before entering into any specialty; and spoke of the desire on the part of a few to form exclusive organizations, which he argued were highly detrimental, and denounced them severely, saying that medicine, to be beneficial to humanity, must be open to one and all, and, if its practitioners were to be excluded from medical societies and their meetings—not from a lack of knowledge and good standing—such societies had outlived their usefulness. Special studies might be made by physicians in certain directions, but the advantages of their research and study must be verified by their practical demonstration through the general practitioner. Without a thorough knowledge, specialism availed little. This powerful organization should represent every branch and specialty of medicine, and its knowledge should be open to all its members. We were all entitled to the benefits derived from associated investigations. Outside organizations on special subjects would detract from the inter-

est and advantages of our meetings, and the younger members, neglecting the general subject of medicine, dazzled by the apparent brilliancy of a select few, would wander forth to ultimately destroy their own usefulness. The American Medical Association was the representative body of the medical profession of this country, and had been organized and conducted by gentlemen who had grown gray in its service, and whose brows were adorned with chaplets most worthily won, not only at home but abroad. It was for them and for their fellow-members to control the means of disseminating our science, and not for a few, who, at best, formed but a spoke in the wheel of the triumphant chariot of our science. Our young men should learn that knowledge must come to them by the co-operation of their professional brethren from all parts of our country rather than from a few, who, in their exclusiveness, set themselves above the active members of the greatest and most humanitarian of all professions.

HONORARY MEMBERS.—DR. WATSFORD and DR. STEENS, delegates from the Canadian Medical Association, were made honorary members of the Association, and invited to take seats on the platform.

THE ADDRESS IN OBSTETRICS.—The chairman of the section in obstetrics and diseases of women, DR. T. A. REAMY, of Cincinnati, said that he would depart from the usual custom of giving a review of progress in the department, and would refer the members to current literature for the same. He read notes of 231 cases of laceration of the cervix uteri in which he had operated. Six of the operations had been followed by parametritis, perimetritis, or peritonitis. In 2 the symptoms were sufficiently severe to cause material delay in recovery, and one patient was confined to bed for three months. All finally recovered. In 170 cases the laceration was bilateral, in 30 unilateral. Of the latter, 23 were on the left side and 5 on the right side; 16 were stellate, in two of which there were four distinct lacerations. In 5 cases there was laceration of the posterior lip only, in 2 of the anterior lip only. In 80 cases the laceration was extensive. In 15 of the 80 the laceration extended to the cervico-vaginal junction on both sides; in 23 of the bilateral cases it extended to the cervico-vaginal junction on one side only. In 3 cases the rent extended to the internal os. In one of these cases the vaginal wall was also extensively lacerated, and the peritoneal cavity had probably been opened. The patient had been an invalid for three years. Twelve sutures were required on one side. The patient was restored to robust health within six months after the operation. In 167 cases a perineal operation was done. The anal sphincter was damaged in 15 cases; in 7 the recto-vaginal septum was opened up. In 26 cases he operated upon the cervix and the perineal body at the same sitting. In 5 of this series of cases he curetted the uterine canal at the same sitting. In none of the 5 cases did a single bad symptom arise. In 50 cases he operated upon the perineum subsequent to the operation upon the cervix. In not a single case did secondary hemorrhage occur after trachelorrhaphy. Hemorrhage during the operation was controlled by a stream of hot water. In only three cases was he under the necessity of using forceps. He had dispensed with sponges. He emphasized the importance of allowing free bleeding in most cases after denuding the surface. He practiced thorough denudation, cutting out all cicatricial tissue, and allowed free bleeding—points which were important in overcoming subinvolution. The form of delivery had been learned in only a few of the cases. In his opinion, the influence of laceration of the cervix in producing cancer had never been fully comprehended by any author. Dr. Emmet deplored the extent to which the operation was being done, but Dr. Reamy thought without just cause. With regard to the influence of the operation on ster-

ility, he knew of thirteen cases in which conception had occurred subsequent to the operation, delivery taking place at term. He had attended six of the patients in subsequent labor, and in none was there a fresh laceration. He believed the operation favored fertility and often cured sterility. In but two cases had it proved a failure, and in each of these its repetition was successful. In performing the operation the cervix should not be drawn down farther than could be avoided. Outline the denudation with a sharp knife, and cut the tissues included within the line with sharp scissors. He employed a needle shaped nearly like half a circle, with a very sharp point, armed with Chinese silk. The sutures were not cut off, but allowed to hang out, extending nearly to the vulva, for easy extraction. The vagina was washed out immediately after the operation with the return-current syringe, the nurse washed the vagina with warm carbolized water within an hour after the operation, and the syringe was not employed again for six days.

The paper was referred to the section in obstetrics.

DR. FREDERICK HORNER, a delegate from the Virginia State Medical Society, read some resolutions, but they were declared not in order.

VIVISECTION.—DR. HENRY SMITH, of Pennsylvania, then offered the following, which, after being warmly discussed by Dr. Keyser, of Philadelphia, and Dr. J. C. Dalton, of New York, were adopted with but one dissenting voice, that of a lady:

Whereas, It appears that an effort is being made to restrict by legislative action the practice of investigation in medical science by experiments on animals; and

Whereas, In the opinion of this association, such restriction is not needed for the guidance of medical men in their investigations, and would be an injury and a hindrance to the pursuit of medical knowledge and the improvement of the medical art; therefore,

Resolved, That a standing committee of seven, with power to increase its number, be appointed by the President of the association, to be known as the "Committee on Experimental Medicine of the American Medical Association," charged with the duty of opposing, by all legitimate means, any interference with the progress of medical science by unwise or illegitimate legislation.

The PRESIDENT appointed the following gentlemen as said committee; Dr. William Pepper and Dr. James Tyson, of Pennsylvania; Dr. Judson, of Maryland; Dr. J. C. Dalton and Dr. Austin Flint, Jr., of New York; and Dr. John S. Billings, of the army.

ADVERTISING BY PHYSICIANS.—DR. ATWOOD, of St. Louis, on the part of the St. Louis Medical Society, memorialized the association in a paper earnestly decrying the practice of physicians connected with medical colleges, dispensaries, etc., of taking advantage of their official position to advertise themselves, although in an indirect manner. The paper, according to the rule, was referred to the Judicial Council.

THE STANDARD OF MEDICAL EDUCATION.—DR. D. BENJAMIN, a delegate from the Maryland State Medical Society, offered the following resolution:

Resolved, That this association earnestly urges upon all American medical colleges the necessity of elevating the standard of medical education, at least so far as to require a preliminary examination, a three-years course, a registry of attendance, and practical demonstrations of diagnostic skill.

The motion was seconded by Dr. BRODIE, of Michigan.

DR. GARNETT said the ground had been covered in the President's address, and he moved that the resolution be laid on the table. The President put the motion to lay on the table, and it was declared carried; but earnest objection was made to

"squelching" attempts to elevate medical education, and it was stated that the President had neglected to call for the nays. The President then again put the question, a rising vote was taken, and the motion to lay on the table was declared lost. The original motion was then earnestly supported by Dr. HENRY, of New York, and, after some further discussion, was put, and carried by a large majority. The President then stated that it was an oversight on his part if he had not called for the nays on the motion to lay the resolution on the table, and added that he was in sympathy with the original motion as adopted.

AMENDMENTS TO THE CONSTITUTION AND BY-LAWS.—Dr. PACKARD, of Philadelphia, moved that certain amendments to the constitution and by-laws, of which notice was given at the meeting at St. Paul, be called up and acted upon after the reading of the addresses to-morrow. Carried.

The Secretary read an invitation from Professor Baird, of the United States Fish Commission, for the members of the association to visit the institution and observe the hatching of shad.

Thursday—Third Day.

The meeting was called to order by the President at 10 A. M., and prayer was offered by the Rev. W. Paret.

VACANCIES IN THE BOARD OF TRUSTEES were filled by appointment by the President as follows: Dr. E. D. FERGUSON, of New York; Dr. W. T. BRIGGS, of Tennessee; Dr. J. E. REEVES, of West Virginia; Dr. J. W. PREWITT and Dr. GEORGE PECK, of the navy; and Dr. D. A. STAMMONT, of Kansas.

THE ARMY MUSEUM AND LIBRARY.—The committee appointed to urge the provision of commodious and fire-proof buildings for the Army Medical Museum and the Library of the Surgeon-General's Office reported that a memorial to Congress recommending that \$5,000 be appropriated for the improvement of the museum had not been acted upon in the committee of Congress; but that the committee had reported favorably to an appropriation of \$10,000 for the library. The report was accepted, and the committee continued.

GOVERNMENT PROVISION FOR SCIENTIFIC RESEARCH.—Dr. GEORGE M. STERNBERG offered the following resolutions, preceded by certain preambles:

Resolved, That we earnestly petition the Congress of the United States to make suitable appropriations for the prosecution of scientific researches relating to the causes and prevention of the infectious diseases of the human race, to be expended under the direction of the National Board of Health; and that a permanent detail of one medical officer of the army and one of the navy be authorized for the prosecution of researches of this nature.

Resolved, That a committee of five members of this association be appointed to present copies of these resolutions to the Speaker of the House of Representatives, to the President of the Senate, and to the chairmen of the Committees on Public Health of the House and of the Senate.

The resolutions were adopted, and the President appointed the following-named gentlemen to constitute the committee: Dr. STERNBERG (Chairman), Dr. ALBERT L. GHION, Dr. I. M. HAYS, Dr. J. C. DALTON, and Dr. J. E. REEVES.

CREMATION.—Dr. KELLER, of Arkansas, offered some resolutions on this subject, but was ruled out of order.

THE SPECIAL COMMITTEE ON THE PRESIDENT'S ADDRESS.—Dr. BILLINGS, the chairman, read a report, and offered resolutions to the effect that a committee of seven, of which Dr. Austin Flint, Sr., should be a member, be appointed by the President, whose duty it should be to extend, in behalf of the medical profession of the United States, to the International Medical Congress about to meet at Copenhagen, a cordial invitation to appoint the next meeting of the International Congress at Washington, for

the year 1887; also, that the committee should have power to elect its own officers and an executive committee to make suitable arrangements for the congress; the committee to have power to increase its number, and to draw upon the association for a sum not exceeding five hundred dollars. The report was adopted.

THE REPORT OF THE BOARD OF TRUSTEES; THE ASSOCIATION'S JOURNAL.—The Chairman of the Board of Trustees, Dr. J. M. TONER, of Washington, read a report which recounted at some length the financial condition of the association during several years past, and the steps that had been taken toward founding a weekly journal. The Treasurer's report was also included. It was believed that at the end of the year there would remain in the treasury, over and above expenses, including the editor's salary, five hundred dollars. It was thought that the rule relating to advertising in the journal, which had been strictly adhered to, had lessened the receipts. As now published, the journal gave six times the amount of reading matter in the course of a year that had been contained in a volume of the "Transactions" as published before, and it was thought that, the financial state of the journal having been found safe, it would prove even of greater value the coming year.

THE EDITOR'S REPORT, included in the report of the Board of Trustees, was made by Dr. N. S. DAVIS. It stated that calculations had at first been made on the basis of 2,500 subscribers, but that the actual circulation had been 3,436, of which 3,271 were among members and subscribers. The advertising had been slowly increasing, and the whole amount received from this source was estimated at \$3,000. The total income for the year had been \$18,547.50; and, after all expenses had been paid, it was thought there would remain a balance of \$500 at the end of the year. Dr. Davis believed that the financial condition of the journal was such as to enable him, should he continue to be the editor for another year, to widen its scope of usefulness by engaging correspondents in more of the large cities, and to justify him in devoting more time to its editorial management.

Dr. TONER then resumed the reading of the report of the board, which stated that the journal had, in its opinion, been conducted with economy, ability, and judgment, the best interests of the profession being kept in view, and its dignity maintained with rare discretion; and it was confidently expected that the experience gained during the past year would enable the editor to greatly improve the journal. Dr. Toner read a letter from Dr. Davis, received in April last, offering his resignation as editor of the journal at the end of the quarter, because he wished to be relieved of an onerous amount of labor on the one hand, and, on the other, because he desired to free the board from all personal considerations connected with questions of future policy. The members of the board, with but one dissenting voice, had requested Dr. Davis to continue in the editorship for another year, and Dr. Davis had replied that the same motives which had led him to yield to the wishes of the board when it first requested him to accept the editorship would lead him to comply with their request again, but that he positively could not serve longer than the year. The board had received proposals from publishers in cities in different sections of the country to publish the journal, but none of them were so reasonable as that of the firm that now had charge of the publication, and the contract with that firm had therefore been renewed.

Dr. PACKARD, of Pennsylvania, offered a minority report, and stated that he had been given to understand that the financial condition of the journal was straitened, and that for that reason the editor had not drawn any of his salary. In his opinion, the journal did not approach in any way to the standard

which the organ of the American Medical Association should reach. He was aware that there were difficulties in the way of starting a journal of this kind, but the defects of the journal of the association had not become less marked during the nine months of its existence. The object of such a journal should be not simply to spread out the minutes of the association over one year—it should be a wide-awake, high-toned periodical in every respect, and not a sectional or partisan organ of the association. Such a journal could be carried on only by a thoroughly trained corps of editors, and at a place where there was access to medical libraries, and where the best auxiliary work could be obtained, such work being liberally paid for. He therefore recommended that the resignation of Dr. Davis as editor be accepted, and that the publication of the journal be transferred to some eastern city, Washington, Philadelphia, or New York.

A motion was made that the minority report be laid upon the table. The President ruled that the majority report should first be acted upon. An appeal having been taken and sustained, the motion to lay the minority report on the table was acted upon. Dr. Beach, of Ohio, called for the ayes and nays. Pending the arrival of the secretary's list of the names of the delegates, the nominating committee reported, after which the secretary announced that the motion to lay the minority report on the table had been carried—ayes, 191; nays, 74. A motion to adopt the majority report was then put and carried.

OFFICERS FOR THE ENSUING YEAR.—The Committee on Nominations reported as follows, through its chairman, Dr. HOOPER: *President*, HENRY F. CAMPBELL, of Georgia; *First Vice-President*, J. S. LYNCH, of Maryland; *Second Vice-President*, S. D. MERCEUR, of Nebraska; *Third Vice-President*, J. W. PARSONS, of New Hampshire; *Fourth Vice-President*, H. C. GHENT, of Texas. The next meeting to be held in New Orleans, beginning the last Tuesday in April, 1885. *Members of the Judicial Council*: J. K. BARTLETT, of Wisconsin; J. H. MURPHY, of Minnesota; J. M. TONER, of the District of Columbia; WILLIAM BRODIE, of Michigan; H. D. HOLTON, of Vermont; A. B. SLOAN, of Missouri; — ULRICH, of Pennsylvania; and W. M. BEACH, of Ohio. *Secretary*, W. B. ATKINSON, of Pennsylvania; *Assistant Secretary*, W. H. WATKINS, of Louisiana; *Treasurer*, R. J. DUNGLISON, of Pennsylvania; *Librarian*, — KLEINSMIDT, of the District of Columbia. *Chairmen and Secretaries of Sections*: *Medicine*, H. D. DIDAMA, N. Y.; G. M. GARLAND, Mass.; *Obstetrics*, R. S. SUTTON, Pa.; J. T. JELES, Ark.; *Ophthalmology and Otolaryngology*, J. A. WHIT, Va.; EUGENE SMITH, Mich.; *Surgery and Anatomy*, DUNCAN EVE, Tenn.; C. B. KING, Pa.; *Diseases of Children*, J. L. PAPE, Tex.; S. S. ADAMS, D. C.; *State Medicine*, E. W. SCHAUFFLER, Kad.; J. N. McCORMICK, Ky.; *Oral and Dental Surgery*, A. W. HARLAN, Ill.; J. E. MEARS, Pa. *Trustees of the Journal*: H. F. CAMPBELL, Ga.; J. H. PACKARD, Pa.; L. CONNOR, Mich. *Chairman of the Committee on Necrology*, J. M. TONER, D. C. *Chairman of the Committee on State Medicine*, J. A. DIBRELL, Sr., Ark.

THE COMMITTEE ON METEOROLOGY.—Dr. N. S. DAVIS, Chairman of the Committee on Meteorological Conditions and their Relations to the Prevalence of Acute Diseases, read a report. The observations regarding acute diseases and their relations to meteorological conditions had not been numerous, owing to the fact that those who saw much of acute diseases had not taken an interest in the matter. The report was accepted, with a recommendation for its publication in the journal.

THE COLLECTIVE INVESTIGATION OF DISEASE.—Dr. DAVIS reported, with regard to the Collective Investigation of Disease Committee, that a proposition from a similar committee of the British Medical Association be accepted—that a central general committee of this association, consisting of seven members, be

appointed by the President, to carry into effect the plan proposed, with power to appoint a sub-committee in each State, either directly or through the State societies, to correspond with the Committee on Collective Investigation of the British Medical Association, and to report annually to this body; and that a sum not exceeding \$300 be appropriated for the use of the central general committee, to inaugurate and prosecute the work intrusted to it. The report and the recommendations contained in it were adopted.

A REPORT FROM THE JUDICIAL COUNCIL stated that, in the matter of Dr. B. W. Day, it had been unanimously decided that the new testimony offered did not warrant the reopening of the case. In the cases of Dr. Good, of Pennsylvania, and Dr. Sherman, of Ohio, whose seats had been contested, the former was not admitted, but the credentials of the latter were accepted.

THE ADDRESS IN SURGERY.—By permission, the address was read by title only. It was on the effects and results of operations for the relief of gunshot wounds of the small intestine.

Friday—Fourth Day.

The meeting was called to order by the President at 9.30 A. M. **VIVISECTION.**—Dr. DALTON, chairman of the committee regarding experimentation on animals, offered the following:

Resolved, That this association desires to express its earnest conviction that experimentation on animals is most useful to promote medical science, and can be intrusted only to members of the medical profession.

Resolved, That the committee be continued. Carried.

THE BOARD OF TRUSTEES.—A question arose whether nominations to fill vacancies in the Board of Trustees should be filled by the special committee on the trustees or by the general nominating committee.

Dr. FERGUSON, chairman of the special committee, offered a resolution to the effect that the committee approved of the nominations which had been made by the nominating committee—namely: Dr. Campbell, Dr. Packard, and Dr. Connor. Carried.

Dr. GRISSOM made a motion declaring it to be the sense of the meeting that the trustees should be nominated by the nominating committee. Carried.

THE COMMITTEE ON THE PRESIDENT'S ADDRESS reported, through Dr. DAVIS, its chairman, that no explanation regarding the code should be made without deliberation. Dr. Davis personally offered the following:

Whereas, Persistent misrepresentations have been and are being made concerning certain provisions of the Code of Ethics,

Resolved, That the President appoint a committee of five permanent members, to report at the next meeting of the Association such explanatory declarations on the subject as the committee may deem proper. Carried.

The Committee on Nominations changed the officers of the section in oral and dental surgery to W. W. ALLPORT, President, and E. C. BRIGGS, Secretary.

THE REGULATION OF IMMIGRATION.—Dr. ROBERTS moved the adoption of the following, which had been offered by Dr. Pratt, and adopted, in the section in State medicine:

Resolved, That we earnestly urge upon Congress more efficient legislation on emigration, so as to exclude from our soil the defective classes of all nations.

Resolved, That the chairman of the section report this to the association for adoption.

The President declared the resolutions out of order at present.

THE INTERNATIONAL MEDICAL CONGRESS.—The following permanent Committee on the International Medical Congress was

appointed: Dr. HAYS, Dr. SAYRE, Dr. JOHNSON, Dr. ENGELMANN, Dr. BROWN, Dr. BILLINGS, and Dr. CAMPBELL.

MEDICAL EDUCATION.—Dr. VON KLEIN, of Ohio, gave notice of proposed amendments to the by-laws, and offered the following resolutions:

Resolved, That no person who shall hereafter graduate from a college where an educational test is not a prerequisite to admission shall be a delegate to the association.

Resolved, That all delegates shall present as a part of their credentials a certificate, from the county or State society they represent, showing from what college and when they graduated, excepting delegates from the army and navy.

OFFICERS OF SECTIONS.—Dr. PRATT proposed an amendment providing that each section should nominate its own chairman and secretary.

THE PUBLICATION OF THE MINUTES.—Dr. PRATT moved that the publishers of the journal be requested to publish in pamphlet form the minutes of the Association, with the constitution and by-laws, for distribution to members at the next session. Carried.

THE REGISTRATION.—Dr. BRODIE offered resolutions to facilitate the registration of delegates. Carried.

Dr. ROBERTSON moved resolutions urging Congress to provide for the Museum of Hygiene. Carried.

It was moved that the nominating committee be not allowed to nominate any of its own members. Laid over one year.

Dr. ROBINSON brought up Dr. Pratt's resolutions on defective immigrants, and moved to lay them on the table. Lost. The resolutions were then adopted.

The Chairmen of the Sections in Ophthalmology and Otolgoy, Diseases of Children, and Oral and Dental Surgery read their addresses by title, and they were referred to the publication committee.

Dr. TONER, of the Committee on Necrology, reported that the notices of deceased members had been published during the year.

On motion, the secretaries of sections were allowed to report directly to the permanent secretary.

Dr. FRANZONI offered resolutions that members should seek to obtain from their States laws elevating medical education. Adopted.

Dr. SEILER proposed an amendment to divide his section into two, namely: 1. Ophthalmology; 2. Otolgoy, laryngology, and rhinology.

THE TREASURER'S REPORT showed a balance of \$2,212. On motion, the annual dues were continued at five dollars.

THE LIBRARIAN'S REPORT was read in part.

Dr. GREEN, of Buffalo, offered resolutions urging Congress to provide for the completion of the third volume of the "Medical and Surgical History of the War of the Rebellion," and to issue a new edition of the entire work at cost. Adopted.

Dr. BEACH offered a resolution urging Congress to take action to exterminate pleuro-pneumonia among cattle. Adopted.

THE PRESIDENT-ELECT was introduced by the President, and made appropriate remarks.

On motion of Dr. BRODIE, it was resolved that the trustees of the journal secure a stenographer at each meeting.

Dr. VON KLEIN offered resolutions abolishing the practice of opening the sessions with prayer. Lost unanimously.

A resolution to drape the next issue of the journal, in honor of the late Dr. Gross, was referred to the publication committee, with power.

A resolution against members signing their names to recommendations of proprietary medicines and mineral waters was carried.

Resolutions were received from the West Philadelphia Medi-

cal Society condemning the efforts of mercenary men to destroy the code of ethics. Dr. WOODBURY moved they be laid on the table; seconded by Dr. Seiler. Lost. The resolutions were referred to the Judicial Council.

Resolutions urging legislation to compel the labeling of chlorate of potash and other like articles as poisons were adopted.

Resolutions from the St. Louis Medical Society, against advertising one's relations with a medical college, were referred to the Judicial Council.

Dr. GHON offered a resolution favoring the erection of a monument in Washington to the memory of Dr. Rush; a committee of seven to be appointed by the President.

Dr. BRODIE moved a vote of thanks in general to the people of Washington.

The President tendered his thanks for the kindness and forbearance shown him during the meeting.

The meeting then adjourned.

NEW YORK SURGICAL SOCIETY.

Meeting of April 22, 1884.

CHARLES MCBURNEY, M.D., Vice-President, in the chair.

(Concluded from page 504.)

CALCULUS REMOVED BY LITHOLAPAXY.—Dr. LITTLE also presented a specimen of vesical calculus which he had removed March 22d from a patient, sixty-six years of age, who presented himself at the Post-Graduate Medical School with symptoms of enlarged prostate and of stone in the bladder. On introducing a sound, he touched a stone without difficulty. The patient was sent to St. Luke's Hospital, where he was etherized and Dr. Little made an attempt to seize the stone and crush it. After working three quarters of an hour he touched it with the sound, but was unable to seize it with the lithotrite. The bladder was, therefore, washed out with Thiersch's boro-salicylic solution, and further operative procedure discontinued. No bad symptoms followed the operation. Two weeks afterward he again etherized the patient, and, after half an hour's manipulating, came in contact with the stone, seized it, but could not retain it in the grasp of the instrument, and was unable to find it again. He then washed out the bladder with the same solution as before. No reaction followed, and the patient was much better after than before the operation. A week later he again tried to seize the stone, succeeded in catching it with a grasp of about three quarters of an inch in diameter, crushed it, and, after that, broke up the separate fragments, without difficulty, removing them with the evacuator. The patient made a good recovery. On examining the fragments, he found that the stone was a round, flat one, and this was probably the reason why he had failed to grasp it with the lithotrite at the previous operations.

VESICAL CALCULUS REMOVED FROM THE BLADDER OF A WOMAN BY LITHOLAPAXY.—Dr. LITTLE also presented fragments of a stone which he had removed from the bladder of a woman, sixty-five years of age, accompanied by the following history, furnished by Dr. William R. Larkin, acting house surgeon to St. Vincent's Hospital:

"Her father passed at frequent intervals small phosphatic calculi *per urethram*. The rest of the family were always very healthy. The patient states that she has always been healthy until two years ago, when she began to experience some difficulty in voiding her urine, especially in cold or inclement weather. The urine passed was slightly turbid and gradually grew more and more cloudy. Twelve months ago she had acute retention, necessitating catheterization. Three months ago she had a second attack, and was relieved by the catheter, and since that date she has had her urine drawn at frequent intervals. Since her second acute attack of retention she has passed blood and an

abundance of mucus. She states that when she first noticed the trouble caused by urination, two years ago, she had also frequent attacks of severe lancing pain, especially marked and intensified on micturition. The pain was referred to the bladder, radiated down the thighs to the knees, and had gradually increased in intensity so that the patient dreaded to pass her water. On admission to St. Vincent's Hospital the patient looks careworn, her face is pale, her pulse is rapid but strong, her appetite and general condition are quite poor, and she suffers from loss of sleep. On examination, a vesical calculus, rather large and somewhat soft, was found. A day was appointed for its removal, but in the mean time a painful carbuncle appeared on the right buttock, in consequence of which the operation was postponed. On April 5th the patient was anesthetized and litholapaxy successfully performed. No difficulty was found in seizing the stone. A short lithotrite (Thompson's), belonging to Dr. George A. Peters, was used. This was much easier managed than the long instrument for the male bladder. A straight evacuating catheter, No. 29 (F.), was introduced, and the fragments were removed by Bigelow's evacuator. Before the catheter was introduced the urethra was slightly dilated by means of Dr. S. D. Powell's four-bladed dilator. After the operation the bladder was thoroughly washed out with a solution of boro-salicylic acid and the patient put to bed. The subsequent progress of the case was entirely favorable. Two weeks after the operation the patient left the hospital free from all symptoms, and having complete control over her bladder."

Referring to the case of the man, Dr. Keyes said he had in several instances experienced difficulty in attempting to pick up a small flat stone with an instrument having the double curve of Bigelow. He thought it was impossible with the patient in position to pick up a small, flat piece of stone from the floor of the bladder with a lithotrite that had a double curve in cases in which the *bas-fond* of the bladder was deep and precipitous. He had had constructed an instrument without the extra curve in the female blade, and in which the blades came very close together at the tip, with the female blade very thin, and with this he had been able to pick up a thin piece of stone from the floor of the bladder as well as from any other place. In cases of very large prostate symmetrically developed, and a fairly large calculus, an instrument with the extra curve might be of some advantage.

Dr. LITTLE said that the stone was finally seized with a Thompson's lithotrite without the double curve. He also stated that at the two attempts he was unable either to seize or to find the calculus. This case also illustrated, what he had seen in several cases when the patient was suffering from symptoms due to enlargement of the prostate as well as from stone, that the manipulations necessary to the operation of litholapaxy relieved the prostatic symptoms. In this case the patient's symptoms were greatly improved by the attempts to find the stone. This he thought was explained by the dilatation of the urethra and the neck of the bladder by the introduction of the evacuating catheters and the large lithotrite, and by the thorough washing out of the bladder. In a case in which he operated last spring, at Woodstock, Vt., the patient, a man seventy-seven years of age, had enlarged prostate, and had been compelled to use a soft catheter every hour for nearly three months. Immediately after the stone was removed, which was a large one, measuring an inch and a quarter in diameter, he was able to hold his water for three hours, and on the third day he held it for six hours. This condition lasted for over two months; the prostatic symptoms then reappeared, and the use of the catheter again became necessary.

Dr. BRIDDON had seen two cases of impacted calculus in the urethra. The first occurred in his service in the New York Dispensary and in a child two years old. The patient had symptoms of retention of urine, and the bladder was distended upward to a point midway between the pubes and the umbilicus.

A catheter was introduced and the sensation of passing over a foreign body was experienced in the deeper portion of the urethra, but the instrument entered the bladder and emptied it, and then came in contact with a stone. He appointed the following day for an operation, and the late Dr. Buck was present to assist him. Dr. Briddon retracted the foreskin and discovered that there was a calculus in the urethra, and it was removed. On introducing the staff into the bladder, another calculus was touched, and was removed by perineal incision.

The second case occurred in a child one year old, in his service in the Presbyterian Hospital, within the last year. Retention had occurred two or three times before his admission, and, when he saw the patient, retention was quite pronounced. On the introduction of the catheter a foreign body was found in the deep part of the urethra, but there was no difficulty in passing the instrument beyond the obstruction. In that case he cut the child on the following day and removed a small calculus.

Dr. BRIDDON also referred to the case of a man in whose bladder he found a calculus with a cocks-pur-projection, which he broke off with his finger, and after that was able to feel the remaining portion of the calculus in a sac in the bladder, but was unable readily to get it out. After considerable exertion with a small scoop, he succeeded in tilting out the calculus, which was of about the size of a filbert. The man had returned within the last two or three weeks to the Presbyterian Hospital with another calculus in the bladder. He performed litholapaxy, but had considerable difficulty in catching the stone. He was at work with the instrument in the bladder at least three quarters of an hour, but no reaction whatever followed the operation.

COMBINED ŒSOPHAGOTOMY.—Dr. HENRY B. SANDS exhibited a specimen of stricture of the œsophagus, removed from the body of a child upon whom he had performed the operation of combined œsophagotomy with a fatal result.

The patient was a girl, two years of age, who was admitted into the Roosevelt Hospital on January 10, 1884, on account of a cicatricial contraction of the œsophagus, which had followed the accidental swallowing of a small quantity of boiling lye, ten months previously. Considerable inflammation was caused by the action of the caustic fluid, and easy deglutition was never re-established. Two months after the accident the child was extremely weak and emaciated, but, by the careful administration of liquid food, consisting of milk and raw egg, her condition was greatly improved. Treatment by dilatation was begun in October, 1883, but was soon afterward relinquished as impracticable. When admitted into the hospital, she was etherized and carefully examined. Nothing abnormal could be discovered by inspection of the pharynx, or by introducing the forefinger, the tip of which passed below the level of the cricoid cartilage without detecting any constriction. Exploration with elastic urethral bougies, however, revealed the presence of an œsophageal stricture admitting a bougie 2 mm. in diameter, which was felt to be firmly grasped. Larger instruments were arrested at the orifice of the stricture, which was situated at a point 13 cm. from the central incisors, and presumably just below the upper edge of the sternum. Considerable sickness and nervous depression followed the administration of ether, and the subsequent attempts to dilate the stricture were made without the use of an anesthetic. These trials were made at intervals of from one to three days, except during a period of a week, when mechanical treatment was suspended on account of a sharp attack of diarrhea which rapidly reduced the patient's strength.

Her weight, which at the time of her admission was 22 lbs. 13 oz., fluctuated during the following two months, and once diminished upward of two pounds in the course of a week. At the end of two months, however, she had gained 1 lb. 7 oz. Meanwhile, in spite of persevering attempts at dilatation, the stricture had become narrower and at last impassable. Soon after this treatment was begun, a bougie 3 mm. in diameter was passed through the stricture and into the stomach; at a later period smaller instruments had to be employed, and

these seemed to cause an aggravation of the dysphagia. Three days before the operation, deglutition ceased, and the child's condition became critical. Dr. Sands decided to resort to combined œsophagotomy, which he performed on March 11th, in the following manner: Ether was administered, and the patient's head was extended and rotated toward the right side, a wine-bottle, wrapped in a towel, being placed under the neck, in order to favor extension, as the neck was very short. An incision, extending from the level of the left sterno-clavicular articulation to that of the middle of the thyroid cartilage, was made along the groove between the windpipe and the sterno-mastoid muscle. The inner edge of the latter being exposed, the muscle, together with the carotid sheath and its contents, was drawn outward by a blunt retractor, while the omo-hyoid muscle was detached and held upward. The dissection was then continued in the direction of the œsophagus, being carried along the outer edge of the thyroid gland and tracheal muscles. On dividing the deep fascia, previously held up and rendered tense by two toothed forceps, the œsophagus was readily uncovered, when it was found to be dilated and hypertrophied. It was opened by cutting with a scalpel between two forceps, an elastic catheter having been previously introduced through the mouth. The catheter was then withdrawn, and the margins of the œsophageal wound being held apart by loops of silk, exploration by means of bougies revealed a tight stricture, situated 2 cm. below the episternal notch. After several trials this was passed by a filiform silver probe, two thirds of a millimetre in diameter. On withdrawing the probe, it was found possible to introduce a narrow grooved director, along which a slender pre-probated eye-knife, such as is employed in slitting up the tear-duct, was guided to the orifice of the stricture, when two shallow incisions were made, one being directed forward and toward the right, and the other forward and toward the left. Neither incision exceeded half a centimetre in length, and very little resistance was offered to the knife. No hæmorrhage followed, and, when the knife was withdrawn, it was found possible to introduce an elastic catheter 4 mm. in diameter, which was tied in the wound, the latter being covered with a dressing of iodoform gauze. The operation was almost free from hæmorrhage, and neither of the thyroid arteries was divided.

March 11th, 11 P. M.—Child very restless and weak. Four ounces of milk injected through tube into stomach.

12th, 8.30 A. M.—Temperature, 103.5° F.; pulse, 135; respiration, 38. Patient has passed a bad night, and has failed to rally. Injected milk, 3 iv; brandy, 3 j. During the day a small quantity of milk and brandy was injected every hour, with the occasional addition of a drop of laudanum. At 6 p. m., temperature, 104°; pulse, 180; respiration, 48.

13th.—Patient continued to sink during the night, and died at 4 A. M.

Autopsy, twelve hours post mortem.—The œsophagus was found to be the seat of an indurated tubular stricture 3 cm. in length, the upper end of which was 9 cm. above the cardiac orifice. The œsophageal wall corresponding to the stricture varied in thickness from 3.5 to 4 mm., the caliber being 4 mm. in diameter. Above the stricture the œsophagus was dilated to a caliber of 16 mm. in diameter, while below the diameter was 11 mm. Above the stricture the œsophageal wall was thickened to the extent of 2.5 mm.; below, it measured 1.5 mm.

The effects of the action of the caustic were visible throughout the entire length of the œsophagus, the mucous membrane being in many places opaque, white, thickened, and adherent to the muscular coat. Of the two incisions made at the entrance of the stricture at the time of the operation, only one had left a trace; this was found to be about 4 mm. in length, and extremely shallow, hardly extending beyond the mucous membrane. The peri-œsophageal tissues at the seat of stricture were healthy and uninjured, and no lesions besides those described were found in the thoracic or abdominal organs. An examination of the specimen showed how slight an incision would sometimes suffice to render permeable a stricture which had before proved impassable; and it was greatly to be regretted that the patient had not sufficient strength to survive the shock of the operation, from which she never rallied.

Dr. SANDS also presented a second specimen of stricture of the œsophagus, obtained post mortem from a boy thirteen years

old, who died from peritonitis, following gastrostomy, and upon whom an unsuccessful attempt had been made to perform combined œsophagotomy.

The patient entered the Roosevelt Hospital, February 14, 1884, when he gave the following history: About six weeks previously he was submerged in a vat containing a solution of caustic soda. The injury was severe, causing numerous ulcers of the skin, loss of sight in both eyes, and a stricture of the œsophagus. Soon after the accident the mucous membrane of the mouth began to desquamate, and a week elapsed before he could swallow liquids. A fortnight later he was able to swallow solid food, although deglutition was painful. Three months before admission, dysphagia reappeared, and gradually increased until nothing but liquid could be swallowed. Lately treatment by dilatation had been resorted to, but without benefit. When admitted he weighed seventy-five pounds, and was pale and thin. Examination of the œsophagus revealed a stricture, through which no instrument could be made to pass, situated eleven inches from the central incisors and nearly opposite the middle of the sternum. On the following day a filiform whalebone bougie was introduced through the stricture and beyond it, as far as the stomach. Dilatation was carefully tried nearly every day during the next four weeks, but without success. On one occasion, soon after beginning the treatment, the stricture admitted a flexible catheter 3 mm. in diameter. Usually only smaller instruments could be passed, or the stricture was found to be impassable. By careful feeding, the patient's weight was increased six pounds; it afterward diminished slightly as deglutition became more difficult.

March 18th.—Operation. Ether. Head extended, rotated to the right, and supported by a hard round pillow placed beneath the neck. Incision three inches in length, extending from the level of the middle of the thyroid cartilage to a point opposite the sterno-clavicular articulation. Inner edge of sterno-mastoid exposed, and omo-hyoid divided, to obtain more room. Superior thyroid artery divided between two ligatures. œsophagus exposed, and opened after being raised by two forceps, a flexile catheter having been previously introduced through the mouth. Margins of wound in œsophagus held apart by loop of silk, while attempts were made to pass the stricture, which was situated three inches below the episternal notch. All these attempts proved unavailing, as no instrument could be made to engage in the stricture, whether inserted through the mouth or through the œsophageal wound. Silver and whalebone probes, including the finest, and elastic and filiform bougies, were tried in turn without success. Oil was injected into the œsophagus, and an endoscopic tube was passed down to the seat of stricture, in the hope of rendering it permeable, but in vain. Wound irrigated with bichloride solution and dressed with iodoform gauze, the edges of the œsophageal incision having been previously stitched to the integument, with the view of permitting subsequent exploration.

21st.—Patient fed since last date by rectal enemata, and is in fair condition. Stricture still remains impermeable to instruments inserted through wound, although yesterday it permitted the passage of a fine whalebone bougie (tip 5 F., shaft 8 F.), introduced through the mouth. It was decided to perform gastrostomy.

Operation.—Ether. Incision an inch and a half long, parallel to and a finger's breadth below inferior margin of thorax on left side. Outer border of rectus divided to extent of three eighths of an inch. Bleeding having ceased, peritonæum divided, forefinger passed into abdominal cavity, readily recognizing anterior wall of stomach. This, being drawn forward, was held in position by a loop of stout silk thread, embracing peritoneal and muscular coats. Stomach fastened to abdominal wall by thirteen interrupted silk sutures, introduced through entire thickness of latter, but not penetrating the gastric mucous membrane. Operation performed with antiseptic precautions. Irrigation with solution of mercuric bichloride, 1 to 2,000. Silk sutures prepared according to Kocher's method; iodoform-gauze dressing. Patient not being very weak, it was decided to postpone opening stomach so as to favor adhesion. Nutrient enemata (Leube's beef extract), with a tablespoonful of whisky, every four to six hours.

24th.—Surface of wound in neck looks gray and sloughy. Patient seems to be losing strength. 9 P. M.: Removed dressings from abdo-

men and found wound apparently in excellent condition. Opened stomach with a tenotomy knife, making wound very small, equal only to width of blade. First attempts to puncture were unsuccessful, the knife passing between coats of stomach and not penetrating its cavity. Introduced into stomach a piece of soft-rubber catheter, No. 10 F., which filled the aperture completely, and prevented, at the time, leakage of gastric fluids. The puncture, made without ether, caused no pain. Catheter tied in position and plugged by a wooden peg. Iodoform dressing renewed. Four ounces of milk injected into stomach every four hours. Rectal enemata continued every six hours.

26th.—Neck wound in bad condition. Applied carbolized oil (1 to 12) and iodoform.

27th.—Abdominal wound looks badly, most of the stitches having cut through, and the granulations being bathed in secretions which have escaped from the stomach alongside the tube. Inserted a longer flexible catheter, No. 19 F., and packed wound carefully with iodoform gauze. Patient receives by the stomach three raw eggs daily, and eight ounces of milk every four hours.

28th.—Weaker; slight pain in abdomen; no tympanitis. Wound of neck continues sloughing, and emits a foul odor. Applied solution of chloride of zinc, 40 grs. ad ζ j.

30th.—Died at 11.55 A. M., having failed steadily and developed the symptoms of peritonitis since last date. Elevation of temperature, 101° to 106° F., was observed from the time of the first operation.

Post-mortem Examination showed an indurated stricture of the œsophagus at the point where it had been discovered during life. It measured about 8 mm. in length, and the thickness of the œsophageal wall corresponding to it was 4 mm. The entire mucous membrane of the œsophagus was blanched, thickened, opaque, and adherent. A bougie 3 mm. in diameter could be passed without difficulty through the stricture, just above which the mucous membrane was somewhat uneven and abraded, as if it had been injured by the instruments employed in attempting dilatation. No false passage existed, and the tissues surrounding the œsophagus were normal.

The peritoneal cavity contained a small amount of sero-purulent fluid, and the coils of small intestine were adherent to one another by recent lymph. The adhesions between the stomach and the abdominal wall at the seat of the artificial opening had partly given way, and the evidences of peritonitis were most marked in the neighborhood. The point at which the stomach had been perforated was situated 6 cm. from the pylorus. There was no evidence that the stitches had penetrated the gastric mucous membrane.

Dr. Sands was at a loss to explain his failure to pass the stricture at the time when he opened the œsophagus; but swelling of the mucous membrane, its uneven surface above the contracted orifice, and the lateral position of the wound in the œsophagus, suggested themselves as possible obstacles to success. He regretted his failure, especially in view of the limited extent of the stricture, which was well adapted for cure by internal division. He was inclined to attribute the fatal result of gastrostomy to the low vitality of the patient, which was illustrated not only by a lack of reparative action in the abdominal wound, but also by the unfavorable condition of the wound of the neck. Perhaps if the final step of the operation had been deferred to a later period, a better chance would have been afforded for firm adhesion between the stomach and the abdominal wall, but the increasing weakness of the patient seemed to indicate that further delay would probably cause death by inanition.

The VICE-PRESIDENT referred to a case which he had seen about a year before in a lady for whom aromatic spirits of ammonia had been prescribed. There was also standing near the bottle another bottle of the same size and shape which contained caustic ammonia, and one night she accidentally took a tablespoonful of the caustic ammonia solution, which gave her very great discomfort at the time, but no bad result whatever followed except destruction of the mucous membrane of the tongue and inside of the cheeks. He supposed the absence of serious results was due in part at least to the fact that only a

few minutes before she swallowed the caustic ammonia she had taken a considerable quantity of milk.

Dr. POST referred to a case in which a patient accidentally swallowed a teaspoonful of ammonia, causing great distress at the time, but from the effects of which he ultimately recovered entirely.

Dr. LEROY M. YALE referred to two cases, in each of which the patient had swallowed a drachm of ammonia without injury.

Dr. SANDS referred to the case of a jeweler who swallowed a mouthful of nitric acid, and died two or three days after admission to the hospital. At the autopsy it was found that the œsophagus for its entire length and a large part of the stomach were in a state of gangrene, the slough being quite deep and involving at least the entire mucous membrane. The mucous membrane in the neighborhood of the laryngeal aperture was thickened, but not sufficiently so to cause death from suffocation. The patient also had broncho-pneumonia in both lungs.

Dr. THOMAS M. MARKOE said he was inclined to think that the efforts made by Dr. Sands in his case, as he had had an opportunity to witness them, could not have done any mischief in the way of seriously bruising or otherwise injuring the mucous membrane of the œsophagus. He based this opinion partly on the fact that the manipulation was very carefully performed, and partly on the fact that the mucous membrane of the œsophagus did not easily receive injury. He was still more of this opinion, in view of a case in which he had operated for the removal of a foreign body, where the forceps, introduced from the mouth, was passed down on two successive occasions; a number of other instruments, large and small, were introduced; and the foreign body was seized several times and subjected to traction, with an amount of force which he feared had inflicted considerable injury. But at the autopsy no trace of the operation could be seen. At the time that Dr. Sands was operating he was inclined to the opinion that more force could have been used safely.

Dr. SANDS remarked that his idea was that the use of the whalebone bougie, which was kept up for several weeks early in the case, had possibly diminished the caliber of the stricture.

SECONDARY HÆMORRHAGE FOLLOWING FRACTURE WITHOUT INJURY TO THE ARTERY BY THE BONE.—Dr. STIMSON reported a case of secondary hemorrhage following fracture without direct injury to the artery, occurring in the case of a man, twenty-five years of age, who was admitted to Bellevue Hospital about the middle of March, with fracture of the right leg caused by being run over by a horse-car. The fracture was at the junction of the lower with the middle third; and there was considerable laceration of the integument upon the anterior portion of the leg. The bleeding at the time of his admission was slight. The wound was cleaned with the corrosive-sublimate solution, and through-drainage adopted. On the eighth day after admission a profuse hemorrhage occurred and the patient died a few hours afterward. At the autopsy, on exposing the anterior tibial artery, he found a ragged opening on its anterior surface one third of an inch long, and situated an inch and a quarter above the line of fracture, and immediately above this large ragged opening there was a small pin-hole opening. There was no clot in the vessel, the bone did not press upon it, and there was but little inflammation about it. The posterior tibial artery was thickened and discolored at the same level, and apparently undergoing an inflammatory process which might have terminated in thrombosis or ulceration, as had been the case in the anterior vessel, if the patient had lived longer.

Dr. MARKOE said that at one time he had taken pains to collect a number of cases of secondary hemorrhage after fracture, and in all of them, thirteen in number, he had found the

wound had been manifestly caused by the rubbing of the sharp edge of the bone, either of the fracture or of a necrosed portion, against the surface of the artery.

Dr. STIMSON remarked that in his case there was no possibility of injury occurring from either of these causes.

FIBRO-SARCOMA OF THE KNEE JOINT.—The VICE-PRESIDENT presented, in behalf of the PRESIDENT, a small tumor which had been removed from the knee joint, where it simulated a loose cartilage and was attached by a long pedicle. The tumor measured one inch and a half by one inch. It had been submitted to Dr. Peabody for microscopical examination, who made the following report:

"I have found no reason to change my mind regarding your knee-joint mass, and would only add that the spindle cells are so few in proportion to the fibrous tissue that I should suppose the prognosis to be rather that of a fibroma than of a sarcoma."

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of April 2, 1884.

CRITICISMS, FROM A CHEMICAL POINT OF VIEW, ON SOME FAVORITE PRESCRIPTIONS.—Dr. HENRY LEFFMANN read the following paper:

The few points that I present to the college this evening will include little that is absolutely new, but I think the time will not be entirely wasted, as I know that the prescription list of most of our drug-stores will give numerous examples of the violation of chemical principles here mentioned. My attention was called to this topic by my being shown by an apothecary a prescription calling for—

Syr. hypophosph.,

Tinc. ferri chlor.,

Acid. phosph. dil;

concerning which he said that in the proportions ordered he could never make the mixture up clear. I examined the precipitate, and found in it, as I had expected, a large proportion of the iron and other basic ingredients. This is a simple case of incompatibility. Turning the matter over in my mind, it has seemed to me that, while some attention is paid to cautioning students as to the general nature of incompatibility, very little or none is given, especially in the shallow chemical teaching of many medical schools, to the properties and qualities of chemical substances in their relations to the animal tissues, and the manner of administration. I present here, therefore, a brief consideration of a few well-known remedies.

Under the name of *colorless tincture of iodine* several preparations are used, depending for their popularity on the fact that they do not stain the skin. They are prepared by the use either of ammonia or of sodium sulphite or hyposulphite. They owe their particular property, or rather absence of property, to the neutralization of the iodine, and just to the extent that the iodine is decolorized is it to the same extent deprived of virtue. The free, active affinity of the iodine, to which its local action must be due, is destroyed in these preparations, and the destruction is not slow or uncertain, but in two of the methods mentioned it is sufficiently rapid and definite to be made the basis of a method of quantitative analysis. It is certainly difficult to see how any person could go so wide of simple chemical principles as to invent or employ this mixture.

Potassium chlorate, or, as it is still erroneously called by many, chlorate of potash, is a remedy concerning which extraordinary claims have been made, based upon most erroneous notions of its chemical qualities. It is employed in the laboratory as a source of oxygen; knowledge of this fact has led to its employment as an oxidizing agent in diseases which have

been supposed to express deficient oxidation. I have nothing to say here as to the clinical results obtained from potassium chlorate in any disease, although I believe it is much less in favor than formerly; but I enter a protest against any advocacy of its usefulness as an oxidizing agent. Under temperatures and conditions such as it meets with in the human system, it is one of the most stable of bodies, does not part with its oxygen or chlorine, and, indeed, will not begin to do so except under very high heat. I have found, by actual experiment, that ten grains of the salt kept for two hours at a temperature of 100° F. in contact with an artificial gastric juice did not develop oxidizing qualities sufficient to oxidize one sixtieth of a grain of phosphorus. This experiment is merely confirmatory of what everyday experience with the substance teaches.

Potassium permanganate has been more or less in favor with physicians for a score of years. It is well known as an oxidizing agent; its powers in this respect are well marked. It is as little suitable for internal administration for such purpose as the body just considered, but for an opposite reason. Its chemical properties are developed by almost every substance, and in the doses in which it is given it will be decomposed and rendered inert very shortly after being swallowed. Within a very recent period the salt has come into notice as a remedy for amenorrhœa, and great has been the tribulation of apothecaries. It has been given in pill form, and all the usual excipients have been unavailable. I have made a few tests of the permanganate pills now in the market, and I find, with regard to those made by one of the most reliable houses in this city, that the permanganate is all decomposed and converted into the insoluble manganese dioxide. The preparations of two other manufacturers, made up with some mineral excipient, probably kaolin, were in good condition, but, as soon as placed in a mixture of hydrochloric acid and pepsin, they began to decompose into insoluble manganese oxide. These pills vary in strength from one eighth to one grain; this small quantity of permanganate certainly must soon decompose in the stomach, and the only virtue which it can have is from the manganese itself, and, if this is effective, common sense would seem to suggest that the result could be best obtained by exhibiting some definite compound of manganese—such as the chloride or sulphate. When we consider the chemical relations of the salt, and the almost certain inertness of it in small doses, the gravity with which the learned English therapeutists, who recommended it in amenorrhœa, have discussed the possibility of its producing abortion becomes almost burlesque. I do not desire, of course, to impugn the clinical observations that have been recorded on this point, but I feel obliged to say that, if the insoluble and variable decomposition products of one eighth of a grain of potassium permanganate can affect the function of any one organ, then the difference between us and the apostles of the infinitesimal is small indeed.

I can not dismiss these two compounds, which owe their popularity to mistaken notions of their properties, without saying a word or two as to the exhibition of oxidizing agents. If rational therapeutics or physiological study indicates remedies of the so-called oxidizing class, then it will be found that no better agents are known to us than those which have long been in our hands. In nitric acid, nitro-muriatic acid, and chlorinated soda we have substances which are sufficiently stable to resist the organic bodies of the saliva and gastric juice, and are sufficiently active to give oxidizing effects if such can be obtained other than local action. I have grave doubts whether the nutritious fluids of the body can be oxidized by any method, but there can be no doubt whatever that such effect can not be attained by either a body—potassium chlorate—which yields its oxygen only at a red heat, or by one—permanganate—that decomposes the moment it touches any form of organic matter.

Some years since a correspondent in one of our medical journals gravely recommended the use of raspberry sirap to disguise the taste of potassium permanganate. It was, of course, entirely successful; the taste was destroyed, so was the compound.

Caffeine citrate is a remedy much in favor, and is a remarkable instance of how much physicians take for granted in the remedies they use. There is no caffeine citrate in the market, and it is doubtful whether any such salt can be prepared. The commercial preparations are either pure caffeine or variable mixtures of it with citric acid.

The manufacturers in this city furnish each a different article, except in cases in which they buy from a common source; and a house in a neighboring city furnishes an article which contains no citric acid. Some of the samples are purely bitter in taste, while others are distinctly sour. Analyses of some of the commercial salts are recorded in a paper read before the last meeting of the American Pharmaceutical Association by Dr. G. C. Wheeler. He found the quantities of caffeine varied from 96.5 per cent. to 63.5 per cent.; of citric acid from 63.5 per cent. to 3.5 per cent.; none of these figures correspond with the proportion of a true citrate.

It seems to me that accurate clinical observation can not be made with a preparation of so uncertain a character; for, as seen by these figures, the proportion of active ingredient may vary 33 per cent., and the lesson that these analyses teach us is that when the effects of caffeine are wanted they are best obtained by the use of the pure alkaloid, and not by a pretended and uncertain compound of it.

HISTORY OF A CASE OF PERIHEPATIC ABSCESS.—DR. EDWARD T. BEVEN read the following:

The accompanying specimen exhibits an abscess which has occurred between the diaphragm and the liver. The abscess contained nearly a pint of laudable pus. The superior wall of the abscess was the diaphragm, and the inferior the perihepatic capsule; the hepatic substance was not involved; indeed, the liver was normal. There were evidences of catarrhal inflammation in the colon, and one or two nearly cicatrized ulcers. The only other lesion in the body was found in the right pleural cavity, the lower portion of which was obliterated by inflammatory adhesions.

The clinical diagnosis presented some interesting features.

The patient, a young man, aged twenty-eight, was admitted to the Philadelphia Hospital, November 30, 1883. His previous history indicated that he had suffered from an attack of dysenteric diarrhea four weeks before his admission, although he had convalesced from this attack. He was evidently much emaciated. The temperature until December 8th ranged from 100° to 102°; from December 14th, from 99° to 101°, after which it never rose above 99½° in the evening, and was always 98° in the morning; this continued until the fatal termination of the case on the 20th instant. The pulse was usually above 100. There was occasional sweating; no chills. Extreme tenderness was felt over the hepatic region, associated with pain during the first ten days; the hepatic dullness extending four inches in the nipple line, and about five inches in the axillary region. Physical examination of the chest upon the right side revealed the evidences of a dry pleurisy; there was some cough, which was dry and hard, but not very annoying. Appetite and digestion were fairly good. Urine normal.

The diagnosis of hepatic abscess was made during the first week, chiefly because the symptoms of hepatic lesion, already detailed, were antedated by dysenteric diarrhoea. The pleural lesion was regarded as a secondary inflammatory process engendered by hepatic disease. On December 10th all symptoms of pain and tenderness had vanished; the patient's strength, appetite, and general condition markedly improved; the temperature had fallen to 99°, so that the diagnosis was revised to that of perihepatitis. From December 10th the improvement continued until the 20th, when, after an attack of vomiting, the patient suddenly died.

The autopsy appeared to prove that the inflammation which resulted in the formation of the abscess was primary in the pleura; and the secondary irritation developed the local peritoneal process.

The symptoms of abscess in the hepatic substance are frequently latent. I recall one instance of a patient admitted October 9, 1877, who walked to the hospital and remained under treatment until the 15th, suffering from apparent remittent fever. The day of his death he rose, in the absence of the nurse, and walked down stairs to smoke a pipe; that afternoon he had a hæmorrhage from the bowels and died. The temperature of this patient was between 99° and 101°, and the clinical diagnosis was remittent fever, or typhoid of the variety called ambulatorius. The autopsy revealed an abscess of about the size of a fetal head, occupying the convexity of the right lobe of the liver.

In the case I have reported this evening, the subsidence of pain and tenderness and the temporary improvement of the patient certainly misled me. Under similar circumstances, I should certainly introduce an aspirator, as I was inclined to do in the beginning of this case, because I am satisfied that the healthy liver can be punctured by a fine needle without damage, whereas either a hepatic or perihepatic abscess may at any time prove fatal by rupture.

Finally, if my explanation of the ætiology of this abscess is correct, the case is interesting, as showing the relation of pleurisy to serious perihepatitis.

Reports on the Progress of Medicine.

OTOLOGY.

By CHARLES STEDMAN BULL, M.D.,

LECTURER ON OPHTHALMOLOGY AND OTOTOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY; OPHTHALMIC SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN AND TO THE NURSERY AND CHILD'S HOSPITAL.

EPILEPSY PRODUCED BY A FOREIGN BODY IN THE EXTERNAL AUDITORY CANAL.—Küpper ("Arch. f. Ohrenheilk.," xx, 3) reports an interesting case of this kind in a young woman aged eighteen. Six weeks before Küpper saw her she had been attacked with severe pain in the right ear, which lasted for several days, and was relieved by a discharge of pus from the ear. Three weeks later, having severe toothache, she, by the advice of a friend, placed a small piece of some root in the inflamed ear, which she could not subsequently remove. Since then she has suffered frequently from epileptic attacks, sometimes having had several in a day. The convulsions are always violent and she is unconscious. The watch could only be heard when in contact with the ear, and the tuning-fork was heard better on the side of the inflamed ear. The region in front of the inflamed ear was very sensitive and the auditory canal was full of pus. When the canal was syringed, vomiting and vertigo were produced. The canal was found nearly filled with polypi. These were removed under anesthesia. The next day, after careful washing of the canal, a dark body was seen firmly imbedded in the canal. The patient was again anesthetized and the foreign body was removed with a hook, and proved to be a small piece of wood, 1 cm. long, 0.5 cm. thick. The patient had two epileptic attacks afterward, and since then there has been no return. The purulent otitis was subsequently cured.

CEREBRAL SYMPTOMS FROM OBSTRUCTION OF THE EXTERNAL AUDITORY CANAL.—In the same journal the same author reports a case of this nature occurring in an old woman aged

seventy-six. Violent headache and vertigo, vomiting spasms of the muscles of the face and extremities, came on without any known cause. The patient also complained of pain in the right ear, which was also very sensitive. The external auditory canal on the right side was completely plugged, the hearing was gone, and the bone-conduction was also nil on the right side. An attempt to remove the plug by syringing produced vertigo, vomiting, and violent convulsions. These attacks were repeated during the night. The next day another attempt was made to remove the plug by syringing, but only small bits came away. This, however, relieved the symptoms considerably, and the convulsions ceased entirely. On the next day the plug was removed entirely, and an examination showed that the membrana tympani was pressed closely against the internal tympanic wall, was cloudy, thickened, and immovable, and adherent throughout to the inner tympanic wall. Inflation produced no change in the appearance, and the hearing power was entirely absent. Eight months later the patient was again examined, but no change had occurred.

AN OBSCURE CASE OF SUPPURATION OF THE MASTOID PROCESS; TREPHINING.—F. Tilden Brown ("Zeitschrift für Ohrenheilkunde," xiii, 1) reports an interesting case of this nature in a man, aged forty-eight, which had begun as a purulent otitis media. The case was somewhat obscure from the beginning, owing to the entire absence of tenderness, heat, and swelling over the mastoid process, and to the long-continued pain in the region of the occipital protuberance. Even after the operation had been done, both diagnosis and prognosis were further complicated by the difficulty of distinguishing the symptoms of an attack of facial erysipelas which supervened from those of a meningitis.

OTTIO REFLEX PARALYSIS OF THE TROCHLEAR MUSCLE.—Moos ("Arch. of Otolaryngology," xii, 3, 4) reports a case of this kind in a man aged fifty. The mastoid process was involved, and there was probably some grave intracranial complication. There was no ophthalmoscopic evidence of any cerebral disorder, and no ocular lesion save the paralysis of the superior oblique muscle. Basilar meningitis or propagation of the inflammation to the cavernous sinus would afford a ready explanation of the disturbances in the function of the first branch of the fifth pair and of paralysis of the fourth. The temperature curve was also in accordance with phlebitis and thrombosis without disintegration of the thrombus. If we reject the theory of the presence of a phlebitis and thrombosis of a larger cerebral sinus, on account of the normal fundus of the eyes, nothing remains but to suppose that the retention of pus in the middle ear produced an irritation of the labyrinth, which did not extend to the cerebellum, but rather to the center of innervation of the trochlear nerve of the affected side. This irritation caused a reflex paralysis in the corresponding muscle, which gradually disappeared as its cause subsided.

THE ETIOLOGY AND SYMPTOMATOLOGY OF AUTOPHONY.—Brunner's article (*Ibid.*) is based upon an examination of five cases. He concludes that, apart from the cases in which autophony was produced by cicatricial contraction in the pharynx, it seems chiefly to accompany acute and chronic naso-pharyngeal and tympanic catarrhs. Its cause he considers to have been a patulousness of the tube, in consequence of the insufficiency of the valve-like closure of the pharyngeal orifice, or an alteration of equilibrium in the parts, with a tendency to rupture of the closure; possibly also a spasm of the dilator muscles. The sonorous, trumpet-like sound of the voice is the result of a change in the conditions of resonance. The ear is accustomed to receive sound-waves which impinge upon the drum-head and chain of bones from without, and for this kind of transmission resonance is evidently as much as possible eliminated. The

conditions are entirely different if the sound-waves enter the drum through the tube, in which case the column of air in the middle ear and the walls inclosing it are easily excited into co-vibrations.

A SUBJECTIVE AUDITORY SENSATION PRODUCED BY EYE-GLASSES.—Moos (*Ibid.*) reports the case of a woman, aged sixty-one, who noticed a peculiar ringing in her left ear whenever she put on a pair of eye-glasses, and this was accompanied by a loud beating noise if she persisted in wearing the glasses. Moos considered that the high ringing tone was not the subjective perception of the muscle-noise of the stapedius, but a subjective sensation of hearing caused by the negative-pressure fluctuation of the labyrinthine fluid, occurring when the contraction of the ocular muscles during the application of the eye-glasses excited the stapedius muscles to concomitant activity.

THE PHYSIOLOGICAL SIGNIFICANCE OF THE TRIGEMINUS AND SYMPATHETIC NERVES FOR THE EAR.—Berthold, in a second paper on this subject (*Ibid.*), criticises the views of Baratonx and Kirehner, and maintains his former views as to the physiological importance of the sympathetic nerve; that it is a vaso-motor nerve, and, so far as his experiments extend, a vaso-constrictor nerve for the entire ear (external, middle, and inner ear), as the blood-vessels always contract when the nerve is irritated. The results of division of the nerve, in regard to the blood-vessels of the middle ear, are negative.

THE INFLUENCE WHICH THE TREATMENT OF ONE EAR EXERTS UPON THE OTHER.—Eitelberg (*Ibid.*) formulates the results of his investigations: 1. The treatment of the one ear causes a distinct improvement in the hearing of the other, in a large proportion of cases; it rarely causes diminution of hearing. 2. The greatest improvement in the hearing on the non-treated side was noticed in cases of unilateral, acute or chronic, suppurative inflammation of the tympanum. It was discovered also that the hearing power on the side that was not treated, presuming, of course, that the disease had not already invaded that ear, could be restored to the normal amount before the morbid process upon the affected side had run its course. 3. When both ears are affected, the treatment of either one exclusively often produces an improvement in the other, not merely so far as concerns the hearing, but as concerns any subjective noises that may have been present. 4. In most of the cases under observation, the ear that had not been treated did not generally return at once to a normal condition, but only after a moderate lapse of time. 5. In other cases, the hearing, which had at first been restored in the one ear by treatment of the other, gradually decreased.

DIPHTHERIA OF THE AUDITORY APPARATUS.—Moos and Steinbrügge (*Ibid.*) describe six temporal bones, taken from three children who had died of diphtheria. All the specimens were taken from children, either under or just over one year of age, who had died from diphtheria of the pharynx or of the upper air-passages. In two of the preparations the cartilaginous auditory canal was wanting. In the remaining petrous bones the epidermis of the canal was either detached or could be readily peeled off, but in only one case was pus present. Perforation of the drum-head was seen but once. In six cases nothing could be seen of the hammer, excepting the short process in one case. The microscopic examination revealed in all cases intense injection, great fullness of the vessels, and extravasations of blood in the vicinity of the vessels, while infiltration with pus-cells was seen in only one half the cases. The membrana propria was intact in all the cases except the first, in which granulation-cells were found in a narrow cleft between the radial and circular layers. The mucous membrane of the tympanic membrane showed in all the cases great fullness of the vessels and many extravasations of blood; furthermore, in-

filtration of small cells in some of the cases and of pus-cells in most of them. The tympanic cavity contained either mucus and pus, or tenacious mucus alone, or mucus, pus, and blood, or granular cells, or small fibrous masses. In all the cases the lining membrane of the promontory was increased in thickness, the blood-vessels were enormously full, and the extravasations of blood were here recognizable by the naked eye. In one half the cases there was simple infiltration of the mucous membrane, with round cells, in the other half round cells and pus-cells were found together. The mucous membrane lining the antrum was changed in the same manner. The labyrinth was found to be normal in every respect, the only change being a coagulation of the lymph. The reporters were not able to decide whether the changes in the middle ear occurred simultaneously with and independently of the diphtheritic affection of the naso-pharyngeal cavity, or whether the disease extended by continuity through the Eustachian tubes to the ear. They think, however, that the disease of the middle ear either followed one of the milder forms of diphtheria or corresponded to the initial stage of this disease, since the membranous deposits could be readily removed, were easily broken up, and did not present the appearance of true diphtheritic membranes. They call special attention to the absence of micro-organisms in all the diseased parts.

THE HYPHOMYCETES (*ASPERGILLUS FLAVUS*, *NIGER* AND *FUMIGATUS*, AND *EUROTIUM REPENS*), AND THEIR RELATIONS TO OTOMYCOSIS *ASPERGILLINA*.—Siebenmann (*Ibid.*) has a long and interesting paper on the aspergillus fungus in the ear, based mainly upon his own observations. He agrees with Wreden in regarding these aspergilli as genuine parasites that penetrate the skin. He thinks that there are four things necessary for the origin and growth of the various forms of aspergillus vegetation: 1. Conidia or spores; 2. A peculiar condition of the *terrain*; 3. A temperature from 20° to 40° C. (68° to 104° F.); 4. A moderately abundant supply of air. In every normal ear there is a temperature of 20° to 40° C., with free access of air, but such an ear is unfavorable as a nidus for fungi, in so far as pure unaltered epidermis is a poor soil for aspergillus; while only when moist, and even then but scantily, does it afford nourishment for the growth of the fumigatus variety alone. It can, therefore, be affirmed with certainty that the latter variety of aspergillus alone can flourish in a normal auditory meatus, and even this only under the rare and abnormal circumstances that the entire district continues moist day after day. It may be said that, almost without an exception, a free layer of serum affords the aspergillus the original, the most favorable, and perhaps, after all, the only possible soil upon which it can flourish. The primary cause is an inflammation of the skin or middle coat, but it must not be one which secretes a serum capable of undergoing rapid decomposition. Everything that has a tendency to transform a suppurative into a serous otorrhœa, or to diminish the amount of the secretion, or to prevent decomposition, favors the growth of fungus. The favorite situation of the fungus pellicle is the tympanic membrane and the inner third of the meatus; more rarely the tympanum, and still more rarely the outer two thirds of the meatus. Aspergillus in the ear rarely clings as a membrane to the epidermis; usually it rests upon the surface of the exposed rete or corium, without penetrating the latter. On the contrary, mycelium of the deeper layers of the thallus may become surrounded by the cells of the rete Malpighii. Subjective symptoms are occasionally absent; generally there are deafness, tinnitus, pain, itching, and a discharge. Deafness and tinnitus are particularly well marked when the fungus grows upon the soil which has been furnished by the secretion from a myringitis. Itching is very rarely absent. The affection is accompanied by a slight aqueous, serous discharge.

Otomycosis has no specially characteristic subjective symptoms. The one significant symptom in a large number of cases is the occasional removal, by scratching, of a fungus membrane from the ear. Among the objective symptoms are a slight reddening of the locality which the fungus is about to attack, injection of the vessels of the manubrium, with absence of the light spot, and a serous secretion generally within twenty-four hours. The scattered, darker, punctiform spots which are usually observed upon the lower side of the membrane are the remnants of old, cast-off membranes. These fungi rarely possess any odor, though occasionally they smell like mold. *Eurotium repens* gives rise to no subjective symptoms. Objectively, it appears as an envelope or covering to ceruminous plugs, either as a fine woolly or greenish deposit, or as a fine sulphur-yellow layer, in which it is mingled with broken-down, discolored, gray or brown conidiophores. *Aspergillus flavus* and *niger* can generally be recognized by the naked eye, while the examination of *Aspergillus fumigatus* and *Eurotium repens* needs the assistance of a microscope. Fresh cerumen is hostile to the growth of aspergillus. Syringing with lukewarm water has frequently cured cases, but alkalies have rarely proved of any use. The sulphates, silver nitrate, strong solutions of carbolic acid, and instillations of oil are contraindicated, because they may excite an eczema. Glycerin and solutions of zinc, alum, or tannin favor the growth of the fungus. Fresh chlorine-, bromine-, or iodine-water, and strong solutions of permanganate of potassium, are extremely efficacious. A four-per-cent. alcoholic solution of salicylic acid is a sovereign remedy against otomycosis. The favorable action of alcohol depends upon the circumstances: 1. That the spirit is very easily diffused as well through dry as through moist membranes, and that it also comes into most intimate contact with the sporangia. 2. That it dissolves the resinous portions of the fungus elements, deprives the latter of their protecting envelope, imbibes the water, and renders the protoplasm incapable of life. 3. That the very qualities which have made alcohol so useful an adjuvant in the treatment of chronic inflammation of the external and middle ear render it invaluable in the treatment of otomycosis. It kills the fungi and diminishes the amount of secretion. The permanent destruction of the *Eurotium repens* can be accomplished by simply removing the old cerumen upon which it vegetates. The prophylaxis against otomycosis may thus be summed up: 1. Do not allow the walls of the meatus to be deprived of their cover of cerumen. 2. Prevent any loss of epidermis. 3. Avoid all unnecessary applications of fats to the ear, as well as aqueous instillations or injections. 4. Be very careful in the use of zinc, sulphate, glycerin, and tannin. 5. Treat all secretory processes of the external and middle ear in the dryest possible manner. 6. Endeavor to prevent all mechanical injuries in cases of eczema. 7. Be careful to cleanse all instruments which have been used for the removal or examination of any fungus membranes from the ear.

THE WATER-JET INFLATION APPARATUS, AND ITS VALUE AS AN AIR-DOUCHE.—Lucæ ("Arch. f. Ohrenheilk.") makes a strong appeal for the water-jet inflation apparatus as a means of giving an air-douche to the Eustachian tubes and tympanic cavities. The apparatus consists of three cylinders, which are connected with each other by two systems of tubes. The uppermost cylinder is connected with the conduit or water-system by a pipe, armed with a stop-cock. The cylinder beneath the first one is in direct communication with the atmosphere and contains two Giffard's injectors, which, as soon as the water begins to run from the first cylinder into the second, suck in air through the opening in the second cylinder. The air and water are thus carried along together and enter the third cylinder, which stands vertically beneath the other two and is much larger than either of them. From the lower end of this third cylinder runs

a leaden tube shaped like the letter U, with one leg much longer than the other, provided with a lateral tube for the escape of the water, and with a regulating stop-cock, which should always be kept open. Between the second and third cylinders is a bent tube, provided with a stop-cock for the exit of the compressed air. Into this tube a mercurial manometer is introduced, and it is then connected with the Eustachian catheter by means of a piece of thick rubber tubing. When the instrument is in operation, the powerful, continuous current of air passes into the middle ear, in a large number of cases, without any assistance on the part of the patient. It can also be used most satisfactorily without the catheter, by connecting the soft-rubber tube with an olive-shaped mouth-piece.

GRAVE DISEASE OF THE MASTOID PROCESS.—Knapp ("Zeitschrift für Ohrenheilkunde," xiii, 1) reports in detail three cases of severe disease of the mastoid process. The first case was that of a man, aged thirty-nine, with acute purulent otitis in consequence of sea-bathing. The occipital bone became perforated, and the cavity of the skull was drained for three consecutive months, but death followed in consequence of abscess of the brain. The second case occurred in a woman, aged forty-five, who had a chronic internal mastoiditis following purulent otitis media. The bone became sclerosed and was trephined. No pus was found, and death followed from meningitis or abscess. The third case was in a man, aged twenty-five, with acute purulent tympano-mastoiditis, accompanied by violent headache. There was neuritis optica. The mastoid was trephined, and the patient recovered with restoration of normal hearing.

Miscellany.

THERAPEUTICAL NOTES.—*Hanamelis Virginica*.—The therapeutical applications of this drug have lately been the subject of discussion in Paris, in the course of which, we are surprised to observe, one of the speakers seems to have been under the impression that the proprietary preparation known as "Pond's extract" was official in the pharmacopœias of Great Britain and the United States. As a contribution to the discussion, Dr. Tison writes to the editor of the "Bulletin générale de thérapeutique" a brief account of his experience with the remedy. His attention having been drawn to its utility in the treatment of varicocities by Dr. Musser's accounts, he has imported the bark and the leaves, and has had an alcoholic extract made from the former, and a tincture from the latter. For internal administration, he uses the extract divided into pills of about three quarters of a grain each; two pills are to be given twice a day, before meals. In the treatment of hemorrhoids, a suppository containing about a grain and a half of the extract is to be used twice a day. The tincture is employed as a local application, but, on account of the irritant action of the alcohol, it is well to combine it with half its bulk of water or glycerin. The author also uses an ointment made with four parts of the extract to thirty parts of vaseline or lard. In cases of varicose veins, he has observed rapid improvement from the combined internal and external use of the remedy.

The Use of Resorcin in Laryngeal Affections.—Dr. Justus Andree ("Centralbl. f. d. med. Wissensch.," No. 8; "Centralbl. f. d. ges. Therapie," April, 1884) remarks that resorcin, employed about the larynx or elsewhere in the body, effectually disinfects the instruments and apparatus made use of, without causing oxidation. Its caustic and astringent action on the tissues is accompanied by a temporary anæsthetic effect superior to that of any other monatomic, diatomic, or triatomic phenol, so that it may be applied to parts that are exceedingly sensitive. Cauterization with resorcin is followed by perfect regeneration of the epithelium, leaving no scar. Its use is particularly applicable in all hypoplastic and desquamative affections of the laryngeal epi-

thelium, and in chronic aphonia. It is a good caustic in the treatment of putrid affections of the throat, especially of the epiglottis and the vocal cords, as well as in a number of varieties of laryngitis. In tubercular ulceration of the larynx, it has a decided calmative effect upon the pain and the cough.

Solidified Creasote for Toothache.—The "Progrès médical" quotes an article from the "Praticien" to the effect that the employment of creasote as an application to painful cavities of the teeth is complicated with the inconvenience that the liquid is apt to give rise to trouble by coming in contact with various parts of the mouth. This may be avoided by mixing it with collodion, in the proportion of ten parts of collodion to fifteen parts of creasote. The mixture forms a sort of jelly, which, besides being more manageable than plain creasote, forms a varnish which seals the cavity and protects the dental nerve-substance from contact with the air.

Codaine and Glycerin Jelly.—In the "British Medical Journal," Dr. G. S. Mahomed calls attention to a preparation that he has had made, being a jelly containing codaine, citric acid, balsam of tolu, and glycerin. He employs it as a palliative in chronic laryngitis, phthisical cough, etc., the idea being that codaine is the least objectionable sedative, while the hygroscopic and mechanical properties of glycerin are of service. He remarks of such preparations that "patients take them more readily than ordinary medicines, and, if unrelieved, are less prone to be discouraged."

Compound Cathartic Elixir.—The "New York and Brooklyn Formulary of Unofficial Preparations," a very useful little volume recently prepared by a joint committee of the College of Pharmacy of the City of New York, the New York German Apothecaries' Society, and the Kings County Pharmaceutical Society, gives the following formula for the preparation of the *elixir catharticum compositum*:

Resin of podophyllum	8 grains.
Resin of leptandra ("leptandrin")	16 "
Alcohol	3 fluidounces.
Fluid extract of senna	2 fluidounces.
Tartrate of potassium and sodium	2 av. ounces.
Bicarbonate of sodium	120 grains.
Syrup	2 fluidounces.
Compound elixir of taraxacum *,	4 "
Elixir of glycyrrhiza, † enough to make	16 "

Dissolve the resins in the alcohol, and add the solution to the other liquids previously mixed, and in which the tartrate of potassium and sodium and the bicarbonate of sodium have been dissolved. The product should not be filtered, and should be shaken up before any portion of it is dispensed. The average dose is two fluidrachms.

* *Elixir taraxaci compositum*, the formula of which is as follows:

Taraxacum	480 grains.
Wild cherry	480 "
Sweet orange peel	480 "
Glycyrrhiza, Russian, peeled	960 "
Cinnamon	120 "
Cardamom	120 "
Canada snake root	120 "
Caraway	120 "
Cloves	120 "
Pure extract of glycyrrhiza	60 "
Alcohol, water	each, a sufficient quantity.
Syrup	32 fluidounces.

Grind the solid substances to a moderately coarse (No. 40) powder, and percolate, in the usual manner, with a mixture of one volume of alcohol and two volumes of water until sixteen fluidounces of percolate are obtained. In this dissolve the extract, and, lastly, add the syrup. If a precipitate should make its appearance in the elixir, on standing, it should be incorporated with the liquid by shaking, before use.

† The following is the formula of the elixir of glycyrrhiza:

Fluid extract of glycyrrhiza	2 fluidounces.
Water of ammonia	16 minims.
Simple elixir, enough to make 16 [fluidounces? (There is a blank in the book.)]	
Mix, and filter if necessary.	

Original Communications.

THE DISABILITY IN DOUBLE, OR SIMULTANEOUS, FRACTURES OF THE PATELLÆ.*

By JARVIS S. WIGHT, M.D., BROOKLYN,

PROFESSOR OF OPERATIVE AND CLINICAL SURGERY AT THE LONG ISLAND COLLEGE HOSPITAL.

WHEN the surgeon meets with an important case that is rare, and the like of which he has not seen before, he naturally turns to the books on surgery for more light, and, if he does not find what he seeks, he feels some disappointment, and has a laudable ambition to make good the deficiency. Now, when the case I am going to describe came under my observation, I had no doubt as to the disability; but the question I asked myself was this, *Is the disability after double fracture of the patellæ generally the same as in this case?* I then found that there was not much literature on this subject. In the next place, I wrote to some of the leading surgeons in this country in regard to cases of double fracture of the patellæ, and the replies, with one exception, were: *I have not observed nor treated a case of double fracture of the patellæ.*

On the 22d of January, 1883, Dr. D. S. came to my office in order that I might examine him for the purpose of testifying as to the extent and results of his injuries in a suit he had instituted for damages against the city of New York. He was sent to me by his attorney.

Dr. S. at that time was about forty-four years of age. He had evidently been in good health. The doctor informed me that he fell on the pavement on account of a defect in the sidewalk, and fractured both patellæ at the same time. The accident occurred on the 29th of May, 1879. Mrs. S. was with her husband at the time of his injury, and corroborated his statements. The doctor was conveyed to his home in New York, where he was treated by the late Dr. Caro, who put the lower limbs of his patient on two posterior splints, confining them and holding the fragments of bone in apposition in the usual way. So far as I could learn from the doctor, his treatment was good.

Dr. S., accompanied by his wife, came into my office, walking with two crutches. His motions were deliberate and slow, and he appeared to exercise much care to prevent himself from falling. The doctor removed a splint from each knee. This splint was devised by Dr. Caro, and was so constructed as to allow only moderate flexion at the knee joint. The doctor then informed me that he was confined to his bed about five months, that he was then able to get up from time to time and sit in a chair, and that in about fourteen months he began to walk with crutches, having his knees supported by Dr. Caro's splints.

Twenty-six months subsequent to the first injury the doctor fell again, and severely sprained the right knee joint. And with the second injury he was confined to his bed about four weeks, when he got up and resumed his crutches and knee splints. The doctor thought he could walk in a little time as well as he could after the first and before the second injury.

In this case I made the following observations, namely:

1. The fragments of the right patella were separated about

one inch. The direction of the separation was from without inward and downward. The bond of union was fibrous, and was less prominent than the bony fragments. The upper edge of the lower fragment was somewhat tilted forward, and presented some projecting points of bone. The motions of the right knee joint were greatly impaired. 2. The fragments of the left patella were separated about three fourths of an inch. The direction of the separation was nearly transverse. The bond of union was fibrous, and was almost as prominent as the bony fragments. There were small bony projections on both fragments. The motions of the left knee joint were much impaired. The left leg could be flexed and extended about twenty degrees. 3. While the doctor was sitting down he was obliged to extend his lower limbs, not being able to flex his legs to a right angle with his thighs. In addition to this, both ankle joints were considerably impaired, contributing to the difficulty of locomotion. The doctor said that he could not walk when the splints were not on his knees, as he had often tried the experiment. His chief difficulty was in going up and down stairs; it was possible for him to walk on the level. Why he could not walk when the knee splints were off was not easy to explain. It might have been on account of the sense of insecurity, or from the fear of falling, consequent upon the derangement of the neuro-muscular apparatus of each knee joint at the same time.

From all that I could bring to bear on the premises out of which to draw a conclusion, I could only make an unfavorable statement in regard to the disability of this man's power of locomotion. He is destined to be a *cripple* during the rest of his life. His disability is very great. If we take this case as a basis for judging, we must conclude that the prognosis, in a case of double fracture of the patella, is very unfavorable in respect to the future use of the lower limbs.

In this place we may briefly consider a few points in regard to the mechanics of the knee joint, since some light may thereby be shed on the extraordinary disability following a double fracture of the patellæ. The lower surface of the patella presents about two square inches of surface to the femoral condyles; the extent of this surface, however, varies in different cases; I have seen it as much as two inches square. This surface, as the patella moves under the pull of the quadriceps extensor, makes an equal pressure on the femoral condyles at all points of contact, during flexion and extension of the leg in the act of locomotion. Now, in order to lift the weight of the body of an average-sized man, under ordinary conditions, with the quadriceps extensor and the femoral lever, the pressure of the patella on the femoral condyles will be anywhere from 500 to 1,500 pounds avoirdupois. But when the body, under certain other conditions, acquires considerable momentum, the pressure of the patella on the femoral condyles may be much greater than this estimate. On the basis of these facts we can readily see the importance of the patella in the act of locomotion, especially in going up and down stairs, for, if we suppose the patella to be very much smaller than it is, or that the tendon of the quadriceps extensor had no sesamoid bone, we would have

* Read before the Medical Society of the County of Kings, April 15, 1884.

undue pressure at one point, or in one line, on the femoral condyles, and the effect might be imagined when we remember that a cubic inch of cancellous bone will only sustain a pressure of about 600 pounds avoirdupois. In fact, there would be serious damage to the femoral condyles under the supposed conditions. As a corroborating fact, we may mention that the patella is sometimes turned upon its edge—a kind of dislocation—and, by the force of the quadriceps extensor, is so firmly driven into the cancellous tissue of the femoral condyles as to prevent surgical skill from detaching it and restoring it to its normal position. In the mean time it must be kept in mind that the patella projects within the knee joint about one fourth of an inch beyond the tendon in which it is an essential part, and that as the patella, with its ligament and tendon, moves in the act of locomotion around the condyloid curve of the femur, the greater stress, and sometimes the greater strain, is, from the mechanical conditions, put on the more anterior and superficial patellar structures; and that the patella, when in the powerful grasp of the quadriceps extensor, consequent on slipping and trying to prevent a fall, has its anterior fibers put under stress and strain mostly at first, and has these fibers broken first in order—when the fracture extends at once backward through the entire bone.

And, moreover, it can readily be demonstrated that the tendinous and fascial structures—as they are expanded in front of the lower end of the femur—converge, as it were, toward the patella from both sides of the limb, and are thus kept in an expanded form over the femoral condyles as the leg is flexed; and, during the flexion and extension of the leg, the tendo-patella and the adjacent fascial and capsular structures are continuously and accurately applied to the uneven surface of the anterior aspect of the condyloid end of the femur in the most admirable manner, so that, when the leg is much flexed on the thigh, and when more force is required to lift and lower the weight of the body, a very much greater surface of the femoral condyles receives the pressure, and hence the condyloid cancellous tissue in actual use is proportioned to the amount of work to be done, and is therefore conserved in its integrity during locomotion.

And, when the patella is fractured, the integrity of the tibio-femoral and the patello-femoral—or, collectively, the knee joint—is more or less seriously damaged in three directions: (1) The relations of the fibers converging to the patella may be materially deranged; (2) the angle of the ligamentum patellæ and the upper end of the tibia is made less; (3) the joint-surface of the patella is more or less deformed; that is, the functions of the neuro-muscular apparatus are more or less materially impaired. And so, if the sense of security possessed by a patient under ordinary conditions of locomotion may be greatly disturbed by a single fracture of the patella, it would be very greatly disturbed by a double fracture of the patellæ.

Now, while it might seem that such a case as above described ought not to result in so much disability, yet, when we come to consider all the mechanical relations of the knee joint, and when we come to consider the results of a few more cases soon to be noted, then we need not be surprised

in regard to the disability resulting from a double fracture of the patellæ. I have made some inquiry in regard to the disability following double fracture of the patellæ, and do not find much that is worthy of record. Dr. H. O. Marcy, of Boston, in answer to a letter of inquiry in regard to a case of double fracture of the patellæ coming under his care some years ago, writes as follows: "I have lost sight of the case referred to for some years. When last seen she could walk on the level fairly well, taking pains to keep the lower limbs nearly straight. Bending the knees gave the fear and, indeed, I believe, the sensation of falling. She had great difficulty in going up and down stairs." Dr. Marcy goes on to describe a case of single fracture of the patella which he treated some years ago, and in which he obtained a good result; that is, there was union by a *short ligament*. The doctor further informs me that about two years ago this patient, by muscular effort, broke this short ligament as well as the other patella at the same instant, making a case of double fracture of the patellæ. This statement is virtually correct, yet we might say that one patella was re-fractured and the other was fractured at the same instant. Further writes Dr. Marcy: "She"—for this patient was a female—"made a very imperfect recovery with long ligamentous union. Oddly enough, the re-fractured patella gave the best result, in marked contrast with the other patella. She can not cross from the road to the sidewalk without help, and walks by keeping the lower limbs stiff and swinging them much as in case of ankylized knee."

Desault informs us that a patient, being cut for stone, had a convulsion, and fractured both patellæ at the same time (Gross). Sir Astley Cooper also mentions the case of a man who fractured both patellæ simultaneously. And what is more to our present purpose, as we learn from the fourth volume of the "International Encyclopædia of Surgery," Callender gives the following points as to the results of a case of double fracture of the patellæ: "I note in the case of a man who had double fracture of the patellæ some years before, that he had lost all power of recovering himself when the body was bent back from the knees, and that he was constantly falling while moving about. The interval on both sides between the fragments was less than two inches and a half."

Now, from these four cases of double fracture of the patellæ—the one noted by Mr. Callender, the two treated by Dr. Marcy, and Dr. Caro's case, reported by myself—we may conclude that the disability after such an accident will be very great; in fact, a patient having had both patellæ fractured at the same time may reasonably expect to become a most deplorable and pitiable *cripple*. Finally, let me note that this subject throws additional light on the disability that may follow a case of single fracture of the patella. And if it may be said that double fractures of the patellæ are so rare that we shall not be likely to meet such a case, let me reply that such an accident may happen at any moment, and then the surgeon who is called to the case will not, we trust, be unthankful for our trying to find out the disability and its cause in double fracture of the patellæ.

TWO CASES OF DOUBLE AMPUTATION OF THE ANTE- RIOR PART OF THE FEET, AFTER ERICHSEN.*

BY JARVIS S. WIGHT, M.D., BROOKLYN,

PROFESSOR OF OPERATIVE AND CLINICAL SURGERY AT THE LONG ISLAND
COLLEGE HOSPITAL.

CASE I.—John Dalton, African, fifty-two years of age, a seaman, was admitted to the Long Island College Hospital, January 15, 1883, having had both feet severely frozen just before his coming to the hospital. This patient said his general health had been good; he appeared to be over sixty years of age. Both feet were swollen, red, and painful; they were dressed with carbolic oil and oakum. The patient was unable to walk, sit up, or stand. He was put to bed in a well-ventilated ward, and given a nutritious diet, milk-punch, iron, and quinine.

For many days it was uncertain where the limit of mortification would be established. And it was not until about the 20th of February that the line of demarcation appeared; and soon after the furrow of separation between the dead and the living tissue became established. It is well to note that during this time the patient did not have any septic fever from the absorption of the local waste products. The furrows of separation, both on the dorsal and plantar surfaces, were somewhat posterior to the metatarsophalangeal joints.

On the 28th of February I performed the following operation on both feet in the presence of the medical class: An incision was made from the base of the fifth metatarsal bone downward to the vicinity of the furrow of separation, thence extended across the dorsum of the foot just behind the wall of limiting fibrin, and then continued upward along the inner side of the foot to the base of the first metatarsal bone. The dorsal flap was then dissected up to within about an inch of the tarsometatarsal joint, when all the metatarsal bones were cut through with a saw. The plantar flap was then made by cutting from within outward, and then the bases of the fifth and first metatarsal bones were disarticulated. The stumps were dressed and treated as open operation wounds, and the patient made a good recovery, having been discharged, able to walk, from the hospital July 15, 1883.

CASE II.—A. Duval, seaman, of African parentage, twenty-one years of age, was admitted to the Long Island College Hospital, January 22, 1884, having had his feet frozen the day previous. About the 10th of February the line of demarcation began to appear, and on the 15th of February the furrow of separation was well formed—just above the heads of the metatarsal bones. On that day I performed the same operation on both feet of this patient that I had performed on the feet of the first patient, with the following exception, namely: after disarticulating the base of the first metatarsal bone of the left foot, I sawed off about three eighths of an inch of the internal cuneiform bone, because it was longer than usual. This operation was substantially a double amputation, after Erichsen. The stumps were treated just as the others were, and have done very well; the patient is now (April 15th) up and about the ward, and will soon be discharged cured.

My experience with these two cases prompts me to make the following remarks, namely:

1. In performing the above-described operation, to make the dorsal flap, and then saw through the metatarsal bones

and finally make the plantar flap, appeared to facilitate the removal of the damaged parts. This method of sawing the bones and making the plantar flap by cutting from within outward is to be preferred to the usual method of making this flap by cutting from without inward.

2. In both cases it was possible, when the flaps had wholly united, to have the scar-tissue exactly in front of the stumps, and the dorsal and plantar surfaces covered with tegumentary tissues, so that the pressure of a boot during locomotion could be well sustained.

3. Leaving on the three metatarsal bases not only increased the plantar surface for pressure, but also made a better foot-lever than Lisfranc's operation, while removing the first and fifth metatarsal bases improved the appearance of the stumps, and did not in any way seem to impede the process of repair.

4. While a double operation of the kind under consideration will leave considerable disability, I am of the opinion that a single operation, leaving one foot entire and unimpaired, would leave a moderate degree of disability in locomotion.

5. In fine, it remains for me to mention the very great advantage arising from treating such stumps with open dressings, thus facilitating the removal of waste products, which are likely to penetrate and burrow under the fascia of the feet.

ANTISEPTIC SURGERY IN PRIVATE PRACTICE.*

BY FRANK W. ROCKWELL, M.D., BROOKLYN,

SURGEON TO ST. MARY'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN: While the principles governing the dressing of wounds in most of our large metropolitan hospitals are based more or less thoroughly on those which were formulated by Sir Joseph Lister, and while few surgeons of extensive hospital experience are willing to submit patients under their care to the risks involved by neglect of these principles, and therefore, even in their private cases, carry out the measures which experience and constant practice have rendered it easy for them to do, there exists a large class of practitioners in our midst, upon whom are constantly devolving the duties and responsibilities of surgical practice as they arise in private cases (such as the treatment of wounds, compound fractures, etc.), who, by their want of familiarity with antiseptic methods and materials, are placed at a disadvantage in the treatment of such cases, under the very circumstances in which improved methods of dressing wounds are likely to be of most benefit to both patient and physician.

For when to the superior advantages of ventilation, diet, and hygiene, as found in domiciliary practice, are added those of infrequent examination and dressing of wounds, the result can not but be to the interest of the patient—a fact with which we are all familiar.

It is for these reasons that I wish to present this paper in connection with that of my colleague, Dr. Fowler, because the results obtainable in hospital wards by the meth-

* Read before the Medical Society of the County of Kings, April 15, 1884.

* Read before the Medical Society of the County of Kings, April 15, 1884.

ods described by him are still more easily reached in private practice and by simpler means.

For the last few years all operations done by myself have been, as far as possible, thoroughly antiseptic, even when cumbrous spray apparatus, jute, oakum, gauze, carbolized catgut, and the numberless appliances of the Lister system were deemed necessary to success, and in the results obtained I have felt well repaid for the trouble expended.

Now, however, that the spray is no longer considered an essential, even by Lister himself, and especially since a larger experience with antiseptics has enabled me to rely with confidence on the results to be expected from the observance of a few simple rules, and the application of dressings which are almost as simple as bandaging itself, I find it perfectly easy to carry out in every essential detail the antiseptic method, even in private practice.

The few appliances and drugs used have been collected together in the small compass of an ordinary tin cash-box measuring ten by seven inches, and consist of the following articles, contained in the upper tray of the box and its divisions:

Four cylindrical boxes or bottles of rubber, each containing two surgical sponges, and filled with five-per-cent. solution of carbolic acid.

A card of silk of different sizes, made aseptic by boiling in a mixture of salicylic acid, bee's-wax, and carbolic acid.

A box of chromatinized catgut, prepared by immersing ordinary violin and banjo strings in chromic acid, 1 to 1,000, and then in sulphurous acid.

A bottle of iodoform, another of naphthalin, and one of styptic cotton.

Another containing carbolic acid, which is so graduated upon its sides as to serve as a measure of proportion in making the two-and-a-half and five-per-cent. solutions; and a similar one containing a solution of the mercuric bichloride in alcohol, M_{xxx} of which represent seven and a half grains of the salt, and are sufficient to make a pint of the ordinary solution. Drainage-tubes, half a dozen cork discs, painted of different colors, labeled carb. acid, 1 to 20, hydrarg. bichloride, 1 to 1,000, etc., and varnished—safety-pins, horse-hair for sutures, gauze bandages (antiseptic), dressing forceps, a nail-brush and a razor, and ten yards of Mead's rubber adhesive plaster on spool.

The lower portion of the box contains a large piece of naphthalinated gauze, measuring five yards in length by one in width, and sufficient for any ordinary dressing. A piece of rubber tissue twenty-four inches square, a Fowler's irrigator, a pair of large shears, and ordinary roller bandages.

A few words in regard to some of the articles named in the above list may be better said here than later in the paper. The *sponges* used should be carefully selected from firm and fine specimens of the article, and prepared in the following manner: While still dry they are well beaten and rubbed until the particles of sand are driven from their meshes; they are then washed in tepid or warm water, and allowed to soak until the water containing them is clean and free from sand; they are then dried again, beaten and washed, and allowed to soak for an hour or two in a solution of sulphurous acid and water (one part of the acid to fifteen of

water); after this they are again washed and kept in a solution of carbolic acid (five per cent.), or mercuric bichloride, until required. At the completion of the operation they are thoroughly rinsed in warm water, taken home, and, if the case has been at all suspicious, soaked a few hours in the sulphurous-acid solution, or a weak solution of chlorinated soda, washed, and returned to their bottles.

Otherwise they should be allowed to stand for a day in a weak solution of carbonate of sodium, to dissolve out any remaining blood-clot, fibrin, etc., and then preserved for use. My own plan is to destroy sponges used about old sinuses in bone, operations for cancer, or in connection with old-standing or suspicious cases of rectal or vaginal disease.

The silk used should be kept in waxed-paper or air-tight boxes until needed, and then placed in the mercuric solution until applied to the vessel or used as sutures. Practically, I have discarded all but the finest Chinese twist for ligatures, and employ only fine catgut for the purpose.

The chromatinized catgut is kept dry in a box, with a little powdered iodoform, and, when laid in the carbolic or mercuric solution just before the operation, is pliable enough for use after fifteen or twenty minutes.

The horse-hair makes an admirable suture as its smooth, non-absorbent surface makes it perfectly unirritating, and, where there is no special tension on the wound's lips, no better could be devised. If deep approximation be desired, a few deep sutures of the antiseptic silk, or silver wire, with firm and equable compression in the final dressing, give the best results.

The drainage-tubes used are the ordinary rubber ones of the shops, or those you will see in the tray, made of the long bones of the chicken or turkey. Those exhibited were made by myself after Deakin's plan, which consists in first boiling the bones well, and then steeping them in a mixture of one part of hydrochloric acid and two of water for ten hours, then washing, cleaning out, and trimming up with scissors, after which they are boiled in a five-per-cent. solution of carbolic acid, and kept for use in the bichloride solution.

So prepared, they will last in a wound for four or five days, and are usually never seen again, if the dressing be retained for a longer period, as they soften and are absorbed.

The gauze bandages are each five yards long, and are simply strips cut and rolled (with antiseptic hands) from a similar dressing to that which occupies the lower tray. After rolling, they are wrapped in waxed paper and kept for use in the tray.

The naphthalinated gauze comes in five-yard rolls, which are about three feet wide, is packed in air-tight tin boxes, and can be obtained, with everything else needed for practical antiseptics, from C. Am Ende, 268 Washington Street, Hoboken.

It is made after a formula originating with Dr. Fowler, and has, so far, answered the purposes to which I have applied it better than any other form of dressing I have used.

To illustrate the use of the materials enumerated, I will imagine their application to a case of ordinary severity; for instance, one of strangulated hernia.

An operation having been determined upon, the surgeon

procures from the family two pitchers, two shallow dishes, a basin, and a tumbler.

In one pitcher the mercuric solution is made by adding π xxx from the graduated phial to every two tumblerfuls of water poured in. A cork label is thrown into the solution, preventing any awkward confusion or blackening of instruments during the operation.

In the other pitcher a five-per-cent. solution of carbolic acid is made by adding from the proper phial three heaping teaspoonfuls to every two tumblerfuls of water. A label is also thrown into this pitcher, and from these two sources of supply the other preparations are rapidly made.

The instruments required are selected and laid in one of the dishes, in the other the sponges, and upon each a sufficient quantity of the five-per-cent. carbolic solution is poured; to this is then added an equal amount of water, thus reducing the solutions to the proper strength of two and a half per cent.

The surgeon's hands are now thoroughly washed, and rinsed in the five-per-cent. solution, and the nail-brush brought into requisition, his assistants, who are to pass sponges or instruments, taking the same precautions. The parts in the vicinity of the proposed wound are now washed and the hair shaved off, after which a thorough application of one of the solutions is made; the surgeon rinses his hands again in the five-per-cent. solution, and proceeds with the operation. This is done without spray, and even the rule in regard to always returning instruments to the solution when not in use may be *partially* neglected, the surgeon laying instruments constantly required on a napkin or a towel wrung out of the five-per-cent. solution and laid conveniently to his hand. This must, however, be *kept* damp, and used as little as possible, since the *habit* of laying instruments down anywhere but in an antiseptic fluid is a bad one and fraught with evil results. The operation concluded, all oozing is carefully checked, and the hands of the surgeon rapidly cleansed in the five-per-cent. solution. The irrigator is now used by filling its tube from the funnel-end and immersing it in the mercuric solution; an assistant holds the pitcher near the operator, and the wound is carefully and thoroughly cleansed. If, on stopping the irrigation, all hæmorrhage is found to have ceased, its lips are brought together with horse-hair sutures, and, *if possible*, without the use of drainage-tubes. (These are, I believe, by no means an unmixed good, and, unless the wound be a deep one, or, from its situation or cause, likely to be attended with profuse serous discharge, I prefer not to use them; in the majority of cases I do not, and have seen the largest wounds heal under one dressing without them. If I fear to close the wound entirely, and have reason to believe that a few days' drainage may be beneficial, I use the de-calcified bone, but trust, in the majority of instances, to equable pressure and thoroughness in cleansing the wound before closing it.) The sutures having been tied, the whole surface of the wound is now thoroughly covered with dry, finely powdered naphthalin, and, as rapidly as possible, covered with a thick pad of the naphthalinated gauze, which has been dipped in the five-per-cent. carbolic or the mercuric solution. A gauze bandage is now snugly applied, the

irregularities and depressions in the vicinity being padded with cotton, cotton-wool, jute, or any material the surgeon prefers. *These need not* be necessarily charged with any antiseptic material, since the protection to the wound is in the naphthalin and gauze, and the cotton acts simply mechanically as equalizing pressure, and *possibly* as a germ filter from without, its own harmlessness being insured by the barrier below. If I fear discharge from beneath, I am in the habit of scattering naphthalin or iodoform thickly upon the outer surface of the moist gauze, which is then covered with a few layers of dry gauze cut from the sheet, and kept in place with a common roller bandage. The patient is now disturbed as little as possible, the parts kept absolutely quiet, and, if I find by the second or third day that no discharge has made its way through the dressing, that no elevation of temperature (or but slight) exists, and that pain is absent, I wait for some indication as to the period of redressing. With most private cases, intelligently cared for, the dressings are very infrequent; often the first suffices, as I feel that after the first forty-eight hours the chance of failure diminishes. I must beg the pardon of the society for what may seem prolixity in the subject-matter of this paper; but when I say that with this dressing and method, or very slight modifications of it, I have had an ovariectomy heal under a single dressing, which was first removed on the eleventh day, have seen such wounds as are made in amputation at the knee joint, leg, thigh, and breast heal with scarcely a rise of temperature or expression of pain on the part of the patient, and this not in a few selected cases, but, as a rule, whose results I confidently expect in most cases submitted to the treatment, I am sure the repetition of detail is excusable.

Exceptions to the rule, of course, occur, but they have been very rare in my experience, and generally traceable to some cause which I could afterward recall.

That the *theory* upon which antiseptic surgery as practiced to-day is based is the true one, I am not at all prepared to say, since the success of many who follow the partial course I have advocated is no longer a matter of doubt. The *practice*, however, is a constant source of gratification to the surgeon and comfort to his patient, and, followed out in its essential details, can not but increase the efficiency of the man who uses it.

I had intended to supplement the paper with the sketches of a number of cases treated with the dressings recommended, but it has already reached too great a length. I may, however, mention the following two briefly, as they show what excellent results may be obtained where formidable traumatism is subjected to their influence:

CASE I.—Bronchocele, removed from a girl of eighteen. The tumor was so large as to interfere seriously with deglutition and respiration, and weighed exactly one pound after removal. During the operation a great number of vessels were tied either with fine silk or catgut, the superior and inferior thyroid arteries and the pedicle ligated with the same, and the sheath of the common carotid artery, internal jugular vein, œsophagus, and trachea exposed from the level of the hyoid bone to the clavicle, yet the patient recovered without a single untoward symptom, was sitting up in her bed reading on the third day, and complained of but slight pain at any time subsequently to that period, what

little she had being caused, I am certain, by the presence of the rubber drain I was compelled to use for the protection of the floor of the wound which immediately overlay the subclavian vessels and pleural cavity.

CASE II occurred just one week ago to-day, in the person of a lady of fifty, from whom I removed an ovarian cyst, which had contracted adhesions to the small intestine and omentum, and required for its removal an incision reaching from three inches above the umbilicus to the pubes, and rather more than the ordinary manipulation within the peritoneal cavity. Several silk and catgut ligatures were left, but, under the simple moist gauze and cotton dressing, the patient is making a painless and, so far, uneventful recovery. She is now beginning to take solid food; has, but with one exception, had an average temperature of 98-80°, only reaching 100° once, and has not yet had even a safety-pin moved in the dressing applied at the time of the operation.*

HOSPITAL ANTISEPTIC SURGERY.†

By GEORGE R. FOWLER, M. D., BROOKLYN,

SURGEON TO ST. MARY'S GENERAL HOSPITAL.

I AM conscious that this title is far too comprehensive, for my present efforts will be limited to a description of the methods most popular with us at St. Mary's General Hospital. I am far too busy a practitioner of our art to find time to visit the other hospitals of this or the adjoining cities; I therefore know scarcely anything of methods there practiced, except that here and there, through the medium of the journals, I catch a glimpse of what they are doing for the advancement of the cause.

In every ward of our hospital there are large stock bottles of a five-per-cent. solution of carbolic acid. Tin basins, towels, and soap are disposed conveniently about, and no orderly would think of bringing anything else but the solution of carbolic acid, diluted with water one half, for the surgeon to wash his hands as he enters and leaves the ward.

It is required of internes that they shall not have visited the mortuary department, nor have handled any gangrenous ulcer, etc., upon the day that they are to assist at an operation. Prior to taking part in the operation they are required to most thoroughly disinfect themselves with soap and a two-and-a-half-per-cent. solution of carbolic acid. After this their hands and arms are dipped in a solution of corrosive sublimate of the strength of one to one thousand.

Besides the ordinary preparation that patients undergo prior to operation, they are here thoroughly washed in carbolized water and soap for some distance beyond the point of operation; if, for instance, it is a foot to be operated upon, the entire leg takes part in the ablution. This is done in the ward, and towels, wrung out of the sublimate solution, are wrapped about the parts until the operation is about to begin. The patient being brought to the operat-

ing theatre, the rubber sheet covering the table is sponged off with the sublimate solution; the surrounding parts, as well as the site of operation, are again drenched with the same. Towels, wrung out of sublimate solution, are folded in convenient shapes and so disposed about the field of operation as to thoroughly isolate it from the rest of the surroundings.

Although corrosive sublimate is the favorite antiseptic with us, yet among the few objections to its use may be mentioned its blackening effect upon bright instruments. For this reason we still adhere to the use of a two-and-a-half-per-cent. solution of carbolic acid as a germicide bath for the instruments. These latter are conveniently arranged in square, shallow tin pans, in the bottom of which are placed folded towels; just before the operator is ready to proceed, the solution is poured upon them.

As we rarely use the spray in the hospital at the present time, the subject of irrigation becomes one of great importance, for we feel that some efficient method must be adopted to prevent the permanent lodgment in the tissues of floating matter from the atmosphere. We know of no method, next to the spray, of accomplishing this object with a fair degree of certainty except by means of irrigation, and by some the latter is considered superior to the former. Frequent irrigation during the course of the operation is most desirable, and for this purpose the corrosive-sublimate solution would be by far the preferable antiseptic were it not for its damaging effects upon the Péan forceps and other instruments in use in and about the wound. For this reason it has never been popular in our operating theatre for irrigating purposes during operations. The two-and-a-half-per-cent. solution of carbolic acid here serves a good purpose; but at the close of the operation, after all instruments are out of the way, and just before placing the sutures, the wound in all its recesses and surroundings is most thoroughly doused with the corrosive-sublimate solution.

We look upon the arrest of hæmorrhage before closing the wound as a very important part of the antiseptic method, and no point of oozing is ever overlooked. It is at once grasped by a Péan or other flat-bladed and ring-handled spring-catch forceps, and, if these accumulate in the operating field so as to be in the way while the operator still continues at work, an assistant is directed to throw a ligature around each one, and whatever it may happen to grasp, without stopping to isolate the vessel. As catgut ligatures alone are used, it is believed that it makes but little difference about the tissues inclosed in the ligature, so long as the hæmorrhage is controlled. Of course, no one would think of including a large nerve trunk. Further, it is thought to be senseless folly to keep removing forceps to see if the oozing has been controlled by pressure, then having to reapply them or resort to torsion, and finally be compelled to tie the vessel. All this involves an extravagant waste of time and much awkward manoeuvring. As only absorbable ligatures are used, and these of an unirritating character, it is not deemed objectionable to have a large number of them in the wound.

It may be of interest to know the method we employ in the preparation of our catgut ligatures. We procure from

* In this case the dressing was not changed until the *eleventh day*, when the dressings were removed, and the wound was found to be perfectly united. The silver and horse-hair sutures were removed, and the dressings reapplied. They were not again disturbed until a week after, when they were entirely removed, and a simple bandage was substituted. The patient has now entirely recovered.—May 2d.

† Read before the Medical Society of the County of Kings, April 15, 1884.

Peck & Snyder, importers, 126 Nassau Street, New York, the best Italian guitar "E" and violin "E" strings, these two sizes being found sufficient for all practical purposes. In their preparation the latest method of Lister is adopted, as follows: The catgut is first immersed for twelve hours in a one-tenth-of-one-per-cent. solution of chromic acid, then dried, and immersed for twelve hours longer in a solution of sulphurous acid of the strength of the British Pharmacopœia. They are then dried and laid away for use. We keep some powdered iodoform in the box with the ligatures. It should be remembered that the strings are almost sure to untwist, unless prevented from doing so, and become thereby useless, when soaked in these solutions for so long a time. In order to prevent this we have adopted the following expedient: The skeins are slipped, just as they come from the importers, upon a round glass bottle upon which they snugly fit; this is filled with sand, so that it readily sinks into the solutions, and here they are kept during the whole process of preparation, and, when finally dried, are removed, and will be found to have retained their original size and shape, the latter a very convenient one. When they are to be used, we cut, say, half a dozen ligatures of about eight inches in length, and place them in a two-and-a-half-per-cent. solution of carbolic acid, or, better still, in the one-to-one-thousand solution of corrosive sublimate. This is done just at the beginning of the operation, and, when needed, they are found soft, pliable, strong, and perfectly antiseptic. They may be relied upon to hold, in a non-suppurring wound, either as ligatures or sutures, for at least ten days.

Next in importance to the securing of every bleeding point, and thereby securing a dry wound before closing it, is the consideration of some simple and efficacious mode of draining away the wound secretions as they occur. As in most hospitals, rubber tubing of different sizes, having perforations in its walls, is the stock material for this purpose. It is cheap, and, upon the whole, quite efficient, although occasionally, it is to be regretted, a sinus is left marking the track of the drainage-tube long after the rest has fully healed. In amputations of the breast we prefer Neuber's absorbable bone drains, and have had some remarkably rapid healing under one dressing with their use. In cases of extirpation of large tumors, where quite a cavity remains, and perhaps several pockets, I have devised and practiced a method called "branched drains." It consists essentially in taking a single stitch, with a needle threaded with catgut-ligature material prepared as before described, in the deeper portion of the wound, and bringing out both ends from the most dependent angle of the wound. This is repeated in different parts of the wound and its flaps, all the strands being thus brought to the lower angle of the wound from different parts of its cavity and lower surface of its flaps. Other strands of the same material are laid along the middle of the wound directly underneath the line of sutures in the ordinary way, if deemed needful. Thus it will be seen that these branching drains, coming, as it were, from every part of the wound-surfaces and leading to the most dependent portion, must drain more efficiently than a single tube or bundle of capillary drains simply laid along the middle line of a large wound-cavity. Being likewise absorbable,

their presence need give the surgeon no uneasiness, and the dressings can remain, but for some reason other than the removal of the drains, until the wound is entirely healed, thus realizing the surgeon's *beau idéal*—viz., perfect healing under one dressing. Attempts other than by this method and that of the absorbable-bone drains to accomplish this latter object have not been made by myself, with one exception. This was a patient in whom, after an amputation of the thigh just below the trochanter, I tried the method of drainage known as "canalization," introduced by Neuber likewise. This consists of punching numerous holes, from a quarter to half an inch in diameter, through the flaps at various points, and relying upon these for drainage from the wound. The case was one of disease of the femur of long standing, the man was in incipient phthisis, and his vitality was far from being good. Yet, in spite of this, the punch-holes were found blocked with partly organized lymph, the cavity of the wound was filled with sero-sanguinolent fluid, and its interior gangrenous from pressure, when upon the third day the dressings were removed on account of a sudden rise of temperature. This is the only case that I have lost, after operation, from pyæmia since I began, understandingly and intelligently, the practice of antiseptic surgery.

As sutures, carbolized silk, horse-hair, silver wire, and catgut hold about equal rank in the estimation of our surgeons, my own practice more recently has been to close operation wounds, which, of course, are expected to pursue an aseptic course, at once with the continued catgut suture. By this means both time and material are conserved, and a much neater line of union obtained. Usually the outside loops of the sutures drop off and come away with the dressings when the inner loops are absorbed. In comparing the irritating qualities of the non-absorbable materials (horse-hair and carbolized silk), we have determined that horse-hair sutures, well cleaned and kept in sublimate solution ready for use, remain rather longer in the tissues without producing irritation, as evinced by slight suppuration along their track, than those of carbolized silk.

When we reach the matter of dressings, we open up the most important part of the subject of hospital antiseptic surgery, for it is the expense attendant upon the use of antiseptic dressings that has been urged by boards of trustees of hospitals, and prevented many surgeons from adopting them in their wards. Now, I would venture to say that even the expense of a Lister dressing, in all its completeness, when intelligently used, with its need for but infrequent change, will compare favorably with the cost of a daily, and perhaps twice daily, application of ointment, lint, plaster, and bandages. The question that meets us at this point is, What are the requisites of an efficient antiseptic dressing? First of all, the basis, or that which seems to hold our antiseptic and serve at the same time as a dressing, must be of a highly absorbent character, and it must be readily obtainable. Furthermore, it must be light and easily molded to the parts operated upon, non-irritating, and readily impregnated with some active antiseptic substance. For this purpose the material in most common use at the present time is absorbent cotton. This substance is, however, in my opinion, very much overrated as a surgical dress-

ing. I have used it extensively, and find that, although there may be a large mass of it surrounding the wound, yet but a very thin layer, and that only lying immediately upon the wound, became saturated with the secretions. A sort of crust is formed by the discharges combining with and drying in the meshes of the cotton, which becomes impermeable to the fluids, and any further secretions must either remain upon the parts under this crust of cotton, or find their way along the surface of the adjacent parts, and finally make their appearance under the edges of the dressings. When the latter are removed, the large mass of cotton-wool is found to be entirely dry, except the thin layer before mentioned. The district covered by the dressings are sodden, and covered by accumulated wound secretions. Such a condition of affairs is certainly not consistent with the proper carrying out of the principles of antiseptic surgery. In small wounds, and where but little discharge is expected, absorbent cotton, impregnated with an antiseptic, may be used; but the principal use to which we put antiseptic absorbent cotton, in connection with the dressing of wounds, is for the purpose of making firm and equable compression, and to fill in and back up the absorbent material proper of the dressing. The article known as Westhorp's antiseptic marine lint is a much better absorbent material than the cotton; its antiseptic properties, however, are but feeble, depending as they do upon a variable proportion of tarry compounds in its meshes. To increase its antiseptic virtues, we have been in the habit of incorporating in it, after picking and carding, naphthalin. The latter, when well powdered, will adhere to the fibers of oakum or marine lint through the medium of the tar in the latter. This makes a good substitute for the cotton, and, thus prepared, is reasonably antiseptic. It, however, is an expensive when large dressings are used, and another objection to its use lies in the fact that there is formed, by its application to the skin, a black scale of tarry, gum-like substance that adheres tenaciously, particularly in regions where the hair is growing; it also hides from the observer the color and other conditions of the wound district. Except, therefore, where but a feeble antiseptic effect is required, but one or two dressings are needed, and these to remain but a short time, the use of this material is not advised.

During the past winter I procured some of the material known as glass-wool, first introduced as an inorganic dressing material by Kummel in connection with his mercuric bichloride. Either because I did not procure as fine a sample as that used by him, or for some other reason, it was found to be so irritating to the skin as to cause me to refrain from using it. Peat, dried and powdered moss or turf-mold, and Esmarch's latest innovation, "*Wald-Wolle*" (pine cones or needles, ground and prepared), we have not tried, for the reason that we found that the easiest to obtain, as well as that which gave the greatest satisfaction in every way up to the time of our first using it as a basis for our antiseptic application, was pine sawdust, dried and forced through a common flour sieve, coarser particles and sticks being thus removed from it. After drying and sifting, we mix it in the proportion of one to one thousand mercuric bichloride, and, in order to prevent the decomposition of the

bichloride and the formation of calomel in the presence of so much organic matter, chloride of sodium, or pure common salt, is added in the proportion of four grains of the latter to every grain of the mercuric bichloride. The following is a good working formula, and sufficiently exact for all practical purposes: Dissolve twenty-four grains of chloride of sodium in half an ounce of glycerin, heated to the boiling point. Then dissolve six grains of corrosive sublimate in half an ounce each of sulphuric ether and alcohol. Mix these two solutions together, and triturate well with one pound of well-dried and finely sifted sawdust. Spread out to dry, and, when the ether and alcohol have evaporated, add naphthalin in the proportion of one part, by weight, to ten of the sawdust. Thus prepared, the sawdust will absorb about four times its own weight.

Iodoform, salicylic acid, and other antiseptics in powder form may be used instead of naphthalin, or the sawdust may be impregnated with carbolic acid, after the manner recommended by Symonds, of Oxford, and thus used to advantage; but, from the non-poisonous and unirritating character of naphthalin, and apparent specific influence over the contagion and spread of erysipelas, besides its, in our hands, well-tried and proved antiseptic qualities, we are fain to believe that it fulfills all the purposes of keeping up an antiseptic atmosphere in the dressings and about the wound. The corrosive sublimate in the absorbent material acts as a most powerful germ destroyer and disinfectant to the secretions as they come in contact with it. Thus we have in the dressing two valuable antiseptics, each of which fulfills a separate office; the bichloride, in the dry state in which we find it desirable to use it disseminated through our dry and absorbent sawdust, would be no bar to the entrance of air laden with germs directly to the cavity of the wound. But the naphthalin in the dressing, which under the influence of the heat of the body is being constantly given off in a gaseous state, keeps up a true antiseptic atmosphere, the gauntlet of which must be run by floating matter in the air finding access to the deep dressing. On the other hand, the somewhat scanty solubility of naphthalin in the wound secretions detracts from its usefulness somewhat in disinfecting them, while the ready solubility of the corrosive sublimate in these secretions, as they percolate into the sawdust pad, at once renders their decomposition impossible.

Desiring to still further increase the absorbent power of this class of dressings, after much inquiry and search I succeeded in obtaining a sample of so-called "wood-flour." This material is similar to the "wood-wool" of Professor Bruns, of Tübingen. After obtaining my first sample of it for trial and becoming satisfied as to its utility, I found it easy to obtain it in any quantity from N. R. Hopkins, Esq., of 72 Duane Street, New York. It is a very finely ground wood fiber, and is used in making oval picture-frames, medallion heads, etc., by hydraulic pressure, in paper-making and similar industries. It absorbs from ten to twelve times its own weight, and is the most highly absorbent material that I have ever used as a wound dressing. I procured a bale of it, for our use at the hospital, weighing about five hundred pounds, at six cents a pound; but I am informed that in smaller quantities it costs about ten cents. Prepared

the same way as described for the sawdust dressing, except that it need not be dried preliminarily, it possesses about three times as much absorbing power as the latter, and costs about one third more. Either is cheap enough, however.

In using the sawdust or wood-flour dressing, it is necessary to have some very coarse gauze with which to make the pads for the dressing. For this latter purpose nothing in my experience is so well adapted to the purpose, handy, and withal so cheap and easily obtained, as the material known as mosquito bar or netting. It is better to render it hygroscopic by boiling it for eight hours in a strong solution of common washing soda and then rinsing it out in clean water to get rid of the alkali. After drying, it may be folded in convenient-sized squares for future use. It is not at all necessary that bags should be made beforehand of the gauze; this is obviated by simply dipping a properly-sized square of the gauze in the one-to-one-thousand sublimate solution; when needed, it is spread out upon a common dinner-plate, or, when such is not at hand, upon the outspread palms, previously dipped in the same solution, of an assistant. Upon this square is piled, in its central portion, what may be judged a sufficient quantity of the sawdust or wood-flour. The pad is completed by doubling in toward the center the free margins of the square of gauze, and there securing them by a single safety-pin previously dipped in the sublimate solution. No protective is required; the pad is placed directly upon the wound and is so disposed that its thicker portion may be in position to receive the discharges from the drains. The pad is supported by naphthalinated cotton, or, what I have found to be equally serviceable for the purpose and which costs less than half as much, naphthalinated jute. A few turns of a roller bandage, applied to hold the dressing in position, is all that is required; no Macintosh nor outer impermeable covering is needed nor desirable. The indications for its removal are the same as in other antiseptic dressings, viz., unaccountably high temperature, excessive pain, or the appearance of the discharges through the dressings.

Such, I would say in conclusion, is a *résumé* of the antiseptic methods in vogue in the surgical wards of the hospital to which I have the honor to be a surgeon. I do not claim originality for all of them, nor can the special method of dressing described be considered as the result of any one man's thought; it is simply the outcome of our own experience and that of others. We fully believe, however, that, with corrosive sublimate and naphthalin as our fixed dressing, and carbolic acid for our instruments, and, again, corrosive sublimate for irrigating (for this we use almost exclusively in redressing, when there are no instruments in the way to become blackened), we practice antiseptic surgery with pleasure to ourselves and profit to our patients.

For the beautifully prepared naphthalinated cotton and jute, samples of which I have the pleasure of exhibiting, I am indebted to Mr. C. Am Ende, of Hoboken, N. J., who has made special efforts to place at the disposal of the profession reliable antiseptic dressings of every kind, including the wood-flour. Mr. G. H. Sohns, of this city, prepares the catgut according to the method above given. The latter gentleman also prepares the sawdust and wood-flour.

POISONING BY QUININE IN TYPHOID FEVER.

By D. S. LAMB, A. M., M. D.,

ARMY MEDICAL MUSEUM, WASHINGTON.

SEVERAL articles on the subject of the use of large doses of quinine in typhoid fever, where their use has been followed by dangerous symptoms, have appeared in late medical publications. In this connection the following case may be of interest:

A little white boy, aged three years, had had slight diarrhoea and a little fever for about a week, but, as he kept about the house, his mother did not suspect serious disease, and therefore did not seek medical advice. About noon, July 11, 1877, he found a package of eighteen three-grain sugar-coated quinine pills, and, so far as could be learned, swallowed them all. Shortly afterward he took some rice and milk. About half an hour after swallowing the pills he complained of pain in the epigastrium. An emetic of mustard, salt, and water was given, and he vomited some food and one pill. He died at 1.10 o'clock, apparently of syncope, and but little more than an hour after the ingestion of the pills. Dr. W. W. Johnston, Dr. Lovejoy, and Dr. Riley (the latter now deceased) were called, but failed to arrive in time to be of service.

It was deemed advisable to inspect the body, and, accordingly, an examination was made by me twenty-three hours after death, the physicians named being present. The body was well nourished, the skin of a citron tint. The head and spinal canal were not opened. The heart was relaxed, the right cavities were empty, the left contained a little fluid blood. The lungs were congested posteriorly. The liver and pancreas were normal. The Malpighian bodies of the spleen were well marked. The stomach was congested, and presented a number of red ecchymoses; it contained some undigested rice, a thick whitish liquid, and one pill, which was white and partly softened. The duodenum was much congested and contained milk coagula, a few grains of rice, and one pill; Brunner's glands were conspicuous and white; the villi were hypertrophied. The upper part of the jejunum was much congested, and contained milk coagula and one pill; all the solitary bodies and Peyer's patches were much thickened, and the peritoneal surface opposite the enlarged patches presented arborescent congestion; the villi were hypertrophied. In the ileum also the villi were hypertrophied, the solitary bodies and Peyer's patches progressively enlarged, and there was the same arborescent congestion as above mentioned; the contents were dark and granular. The cæcum and the ascending and transverse colon were congested, and the solitary bodies enlarged; the contents were soft and greenish, with some fruit-skins in the cæcum. There was a slight extravasation of blood in the gastro-colic omentum. Specimens 8,831, 8,882, and 8,833, Pathology, Army Medical Museum, are from the case, as are also a number of permanent microscopical slides.

From the point of view of the intestinal lesions, the case does not admit of a doubt as to its being one of typhoid fever, although the clinical history is meager enough. The absence of medical attendance is unfortunate in depriving us of more exact data.

Four quinine pills of the eighteen are accounted for, one being vomited and three found at the post-mortem examination, leaving fourteen pills, or forty-two grains, which presented themselves for local effect and absorption to the stomach and the upper part of the small intestine. This

portion of the alimentary tract responded in the form of congestion and ecchymoses. The coincidence of the relaxed heart and, apparently, death from syncope point, as I understand, to the usual manner of death in poisoning by quinine.

Death came speedily in this case, but, as the following and others will show, that is no cause for surprise. Dr. J. W. Wright ("New York Med. Jour.," February 2, 1884, p. 116) reports a case of a child of ten years sick with catarrhal pneumonia after measles. On the tenth day, and by mistake on the part of the nurse, twenty-five grains of quinine were given by the mouth and twenty-five by the rectum. Within two hours the child went into collapse, but subsequently recovered. Of course, it is impossible to tell, either in his case or the one reported by me, how much of the drug was absorbed.

The case appears, therefore, to prove that a child of three years, at the end of the first week of typhoid fever, may die in a little over an hour, and from syncope due to the ingestion of forty-two grains or less of quinine, the quantity absorbed being indeterminate. The case is of further interest in view of the infrequency with which post-mortem examinations are held on the bodies of children dead from typhoid fever. Hænoch reports but ten from his large clinical experience.

A CASE OF CEREBRAL CONGESTIVE APHASIA.

By GRÆME M. HAMMOND, M.D.,

LECTURER ON ELECTRO-THERAPEUTICS AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

Cases of aphasia from localized cerebral congestion, though not rare, are of such infrequent occurrence as to prove interesting, both from a clinical and from a diagnostic point of view.

The patient, who presented himself at Professor William A. Hammond's neurological clinic at the Post-Graduate Medical School, is a man fifty-two years of age, unmarried, and was formerly a liquor dealer, though for the past five years he has not been engaged in any business. He denies emphatically any history of syphilis, and states that up to the time he was first taken with his present complaint he had never had occasion to employ the services of a physician. About the first part of March, 1879, he began to suffer from insomnia, dreams of an unpleasant character disturbed what little sleep he could obtain, and there was a constant singing noise in the ears. He did not consider these symptoms alarming, believing they would pass off by themselves in a little while.

On the 10th of that same month he went into a store to buy some nails, and, without any previous warning of what was about to occur, found he was unable to ask for the articles he wanted. His aphasia was of the atactic variety; there was no confusion of ideas, or loss of memory of words, but the power of co-ordinating the muscles necessary for articulation was lost. This attack lasted about half an hour. At the expiration of that time his speech was suddenly restored and he was apparently as well as he ever had been.

On December 3, 1880, nine months after his first attack, he awoke in the morning and found he was unable to move either his arms or his legs. On attempting to call for help he could only give utterance to inarticulate cries, the atactic aphasia having supervened with the paralysis of the extremities. His speech,

as in the previous attack, was restored in about half an hour, but it was a day before he could move his arms and legs, and three days elapsed before sufficient strength returned to enable him to walk.

Two years and four months later, on March 2, 1883, he was again suddenly seized with atactic aphasia, but no paralysis accompanied this attack. It lasted half an hour. On February 3, 1884, he had his last attack. It was similar in every respect to those preceding it, except that it was unaccompanied by paralysis. At the expiration of half an hour he recovered his speech entirely. At the present time he seems to be perfectly well, his object in appearing at the clinic being to prevent, if possible, the occurrence of any more attacks.

It is impossible to attribute these seizures to any other cause than a localized congestion of the speech tract, and, in the second attack, to an extension of this congestion to the motor areas for the arms and legs. The transitory character of the aphasia and the brief duration of the paralysis exclude the existence of any severe lesion, such as hæmorrhage, emboli, or a tumor, while localized congestion is more clearly indicated by the precursory symptoms of insomnia, noises in the ears, and unpleasant dreams which preceded each attack of aphasia. The treatment prescribed for him was based upon this view of the case, and bromide of sodium was given in fifteen-grain doses three times a day. This treatment will be continued for a considerable length of time, the patient being ordered to report his condition every two weeks.

A CASE OF OEDEMA GLOTTIDIS FROM SYPHILITIC ULCER OF THE LARYNX; TRACHEOTOMY.

By R. B. JESSUP, JR., M.D.,

HOUSE SURGEON TO THE CHAMBERS STREET HOSPITAL.

GERARD ROCKWOODS, aged forty-five, a native of Italy, was brought to the Chambers Street Hospital, in the ambulance, at 10.12 p. m., February 25, 1884, suffering from great dyspnoea. It was learned from his relatives that he had been coughing for four or five months; that, about a week before his admission to the hospital, he had "taken cold," and had been obliged to remain in bed. About three days before he was brought to the hospital he began to notice a difficulty in breathing. This trouble gradually increased until it assumed an alarming aspect, and the ambulance was called.

On his arrival at the hospital the dyspnoea was so severe that he was fairly gasping for breath. He could not lie quiet, but sat up in bed, and, at each inspiration, elevated his chin and braced himself in his effort to breathe. He spoke in a hoarse whisper, and occasionally he coughed in a short, croupy manner. His temperature was 99.5° F. No diphtheritic membrane was seen on the fauces or tonsils.

Steaming cloths were placed around his neck, steam inhalations were given, and internal medication was resorted to. These methods of relief were carried on until 4 a. m. of the 26th, without any good results. He seemed sinking rapidly, and tracheotomy was done as a last resort. At the time of the operation the patient was unconscious, cyanotic, and breathing only six times to the minute. The operation was done in the ordinary manner, with little or no hæmorrhage; and, in about half an hour after it was done, the patient was breathing with ease. He regained perfect consciousness in about three hours, and drank milk freely. At 10 a. m. his temperature was 103.5°; at 6 p. m.,

103°; at 8 A. M. on the 27th, 99.5°. A laryngoscopic examination of the throat revealed the vocal cords covered with a yellowish, caseous material, which could be wiped off, but its nature or origin could not be made out. On the morning of the 28th the temperature was 104°, the pulse 120, and the patient very weak. He gradually sank during the morning, and died at 2 P. M. of the same day.

The autopsy revealed old adhesions over the right side, and on the left side posteriorly; the lungs were normal and well supplied with air; the spleen was normal; the kidneys were slightly enlarged, but normal in structure; the stomach was normal; the liver was large, but normal in structure, with two recent depressions from the dyspnoea on the superior surface; the œsophagus was normal; the larynx had an area of ulceration beneath the vocal cords, extending downward an inch and a half, and being three quarters of an inch in width, laying bare the lower half of the thyroid cartilage, which was ossified and necrosed. The whole mucous membrane was thickened, with a Y-shaped scar about half an inch below the ulcer described above. There were areas of pigmentation on the right leg.

A diagnosis of œdema glottidis was made when he first came into the hospital, but the cause of it could not be made out. The ulcer was, in all probability, syphilitic in its nature, for the scars of old ulcers were found on the leg, and his nose was sunken and deformed. That there was œdema present was not doubted by any who saw him before tracheotomy was done, and even at the laryngoscopic examination the parts were still somewhat œdematous and swollen. The caseous matter seen could not have produced the intense dyspnoea in itself, for it was not tenacious in its consistence, and could be easily wiped away. Authorities agree that the œdema of syphilitic ulcer of the larynx differs from that of tuberculous laryngitis in that it is more gradual, whereas the œdema of tuberculous laryngitis is quite abrupt in its development.

The case is one of interest, taking its ante-mortem and post-mortem history, and should, I am inclined to believe, be added to the few cases of œdema glottidis from syphilitic ulcer of the larynx.

Book Notices.

A Treatise on Bright's Disease of the Kidneys: its Pathology, Diagnosis, and Treatment. With Chapters on the Anatomy of the Kidney, Albuminuria, and the Urinary Secretion. By HENRY B. MILLARD, M. D., A. M. With numerous original illustrations. New York: William Wood & Co., 1884. Pp. xiv-246.

It is to be said of this work, in the first place, that it gives a clear and accurate account of the anatomy of the kidney, well illustrated by drawings, for the most part made by the author. Following the anatomical part, an equally satisfactory section is found on physiology. Chapter VIII is devoted to a consideration of the significance of the existence or non-existence of albumin in the urine, and the general conditions of its occurrence in health and disease. This is a most admirable chapter, and one calculated to do much good. The author clearly points out, what has for a long time been recognized, that albumin may exist in the urine temporarily without signifying kidney

degeneration. On the other hand, he remarks, kidney degeneration may exist without the presence of albumin in the urine. The tests for albumin in the urine are fully discussed, and the possible sources of error with each of them are pointed out.

In regard to the classification and nomenclature of Bright's disease, Dr. Millard considers that all forms of nephritis may be comprised in three classes: the croupous, the interstitial, and the suppurative. He looks upon the waxy and the fatty forms of degeneration as simply intercurrent or consecutive to one of those mentioned, and seems to substantiate his position by deductions from the most recent researches in pathology. It is hard to give up Dr. Grainger Stewart's beautiful and plausible division, founded on Virchow's pathology, but Dr. Millard would, nevertheless, adhere to the classification we have mentioned.

Each form of the disease is fully discussed, with its ætiology, pathology, clinical history, diagnosis, prognosis, and treatment. The section devoted to treatment is particularly valuable, being a *résumé* of what is known on the subject, illumined by the author's experience extending over a period of twenty-six years.

The book adds to the sum total of our knowledge of so-called Bright's disease, and we can heartily commend it.

BOOKS AND PAMPHLETS RECEIVED.

Brain Exhaustion, with some Preliminary Considerations on Cerebral Dynamics. By J. Leonard Corning, M. D., formerly Resident Assistant Physician to the Hudson River State Hospital for the Insane, etc. New York: D. Appleton & Co., 1884. Pp. 234.

A Course of Instruction in Zootomy. (Vertebrata.) By T. Jeffery Parker, B. Sc. Lond., Professor of Biology in the University of Otago, New Zealand. With seventy-four illustrations. London: Macmillan & Co., 1884. Pp. xxiii-397. [Price, \$2.25.]

Handbook of Vertebrate Dissection. By H. Newell Martin, D. Sc., M. D., M. A., Professor in the Johns Hopkins University, and William A. Moale, M. D. Part III. How to Dissect a Rodent. New York: Macmillan & Co., 1884. Pp. iv-169 to 247, inclusive. [Price, 60c.]

Medical Diagnosis, with Special Reference to Practical Medicine. A Guide to the Knowledge and Discrimination of Diseases. By J. M. Da Costa, M. D., LL. D., Professor of Practice of Medicine and of Clinical Medicine at the Jefferson Medical College, Philadelphia, etc. Illustrated with Engravings on Wood. Sixth edition, revised. Philadelphia: J. B. Lippincott & Co., 1884. Pp. 967. [Price, \$6.]

Clinical Lectures on Mental Diseases. By T. S. Clouston, M. D. Edin., F. R. C. P. E., Physician Superintendent of the Royal Edinburgh Asylum for the Insane, etc. To which is added an Abstract of the Statutes of the United States and of the Several States and Territories relating to the Custody of the Insane. By Charles F. Folsom, M. D., etc. Philadelphia: Henry C. Lea's Son & Co., 1884. Pp. xxiv-33 to 550, inclusive.

Elementary Principles of Electro-therapeutics, for the Use of Physicians and Students. With 135 Illustrations. Prepared by C. M. Haynes, M. D. Chicago: The McIntosh Galvanic and Faradic Battery Co. Pp. 426.

A Treatise on Ophthalmology, for the General Practitioner. Illustrated. By Adolf Alt, M. D. Chicago, St. Louis, and Atlanta: J. H. Chambers & Co., 1884. Pp. xvi-244.

Beginnings with the Microscope. A Working Handbook containing Simple Instructions in the Art and Method of Using the Microscope and Preparing Objects for Examination. By Walter P. Manton, M. D. Illustrated. Boston: Lee & Shepard, 1884. Pp. 11 to 73, inclusive. [Price, 50c.]

The Refraction of the Eye. A Manual for Students. By Gustavus Hartridge, F. R. C. S., Assistant Surgeon to the Westminster Ophthalmic Hospital. With eighty-seven illustrations. London: J. & A. Churchill, 1884. Pp. xi-204.

A Text-Book of Pathological Anatomy and Pathogenesis. By Ernst Ziegler, Professor of Pathological Anatomy in the University of Tübingen. Translated and edited for English students by Donald MacAlister, M. A., M. B., M. R. C. P., Fellow and Medical Lecturer of St. John's College, Cambridge. Part II—Special Pathological Anatomy; Sections I-VIII. London: Macmillan & Co., 1884. Pp. xv-371. [Price, \$3.50.]

The Pedigree of Disease; being Six Lectures on Temperament, Idiosyncrasy, and Diathesis, delivered in the Theatre of the Royal College of Surgeons, in the Session of 1881. By Jonathan Hutchinson, F. R. S., late Professor of Surgery in the College, etc. London: J. & A. Churchill, 1884. Pp. 142.

The New Century and the New Building of the Harvard Medical School. 1783-1883. Addresses and Exercises at the One Hundredth Anniversary of the Foundation of the Medical School of Harvard University, October 17, 1883. Cambridge: John Wilson & Son, 1884. Pp. 55.

Congenital Lipoma. By A. Jacobi, M. D., Clinical Professor of Diseases of Children, College of Physicians and Surgeons, New York. [Reprint from the "Archives of Pediatrics."]

Twenty-fifth Annual Report of the Buffalo General Hospital, for 1883.

London Water Supply. Report, etc., No. XXXVIII.

Ueber einen Fall von Tubo-Ovarialcysten-Schwangerschaft. Beitrag zur Entwicklung der Tubo-Ovarialschwangerschaften. Von Fs. Vulliet, o. ö. Professor an der Universität Genf. [Reprint from the "Archiv für Gynäkologie."]

New York and Brooklyn Formulary of Unofficial Preparations. Published by a Joint Committee of Delegates from the College of Pharmacy of the City of New York, the New York German Apothecaries' Society, and the Kings County Pharmaceutical Society. New York: College of Pharmacy Building. Pp. xii-46.

Therapeutische Notizen der Deutschen Medizinal-Zeitung. 1880-1883. Herausgeber Dr. Julius Grosser. Berlin: Verlag der "Deutschen Medizinal-Zeitung," 1884. Pp. iv-100-xxiv. [Price, 1.50 M.]

Address delivered to Students of Medicine in the University of Glasgow after Graduation—Session, 1882-'83. By W. T. Gairdner, M. D., LL.D., Professor of Medicine, etc. Glasgow: James Maclehose & Sons, 1884. Pp. 24.

On the Use of Force in the Treatment of Club-foot. By E. H. Bradford, M. D. [Reprint from the "Boston Medical and Surgical Journal."]

Iodoform in Dental Surgery. By C. F. W. Bödecker, D. D. S., M. D. S., New York. [Reprint from the "Independent Practitioner."]

Western Reserve University, Medical Department, Cleveland, O. Announcement, 1884-'85.

Clinical Notes on Cancer, its Ætiology and Treatment. With special reference to the Heredity Fallacy and to the Neurotic Origin of most cases of Alveolar Carcinoma. By Herbert L. Snow, M. D. (Lond.), etc., Surgeon to the Cancer Hospital, Brompton. London: J. & A. Churchill, 1883. Pp. 96.

On Malignant Disease (Sarcoma and Carcinoma) of the Larynx. By Henry T. Butlin, F. R. C. S., Assistant Surgeon and Demonstrator of Diseases of the Larynx, St. Bartholomew's Hospital. London: J. & A. Churchill, 1883. Pp. 64.

A Study of the Bladder during Parturition. By J. Halliday Croom, M. D., F. R. C. P. E., etc. Edinburgh: David Douglas, 1884. Pp. 73.

Official Register of Physicians and Surgeons in the State of California. By authority of the Board of Examiners of the Medical Society of the State of California. R. H. Plummer, M. D., Recording Secretary.

Lessons in Longevity: Paragraphs on Home Hygiene, and the Art of Prolonging Life. By John B. Hamilton, M. D., Surgeon-General U. S. Marine-Hospital Service, Professor of Surgery in the Medical Department of the University of Georgetown, etc. Washington: William H. Morrison, 1884. Pp. 77.

Clinical Observations on the Use of Jequirity in Trachoma. By H. Knapp. [Reprint from the "Archives of Ophthalmology."]

The Medical and Sanitary Administration of Atlantic Steamships, and the Position of Ship-Surgeons. [Reprints from various medical journals and newspapers.]

On the Importance of Trachelorrhaphy, with Cases and Remarks. By Joseph Taber Johnson, A. M., M. D., Washington, D. C. [Reprint from the "Journal of the American Medical Association."]

Neurological Specialism. Presidential Address delivered at the Annual Meeting of the New York Neurological Society, May 1, 1883. By W. J. Morton, M. D., New York. [Reprint from the "Journal of Nervous and Mental Disease."]

American Copyright League. Partial List of Members, with Additions to March 20, 1884.

The Ninety-fourth Annual Report of the Board of Trustees of the New York Dispensary, January, 1884.

Reports of Leading Chemists on Relative Diastatic Activity of "Maltine" and "Malt (Barley) Extracts."

History of the Discovery of the Circulation of the Blood. By Henry G. Chapman, M. D., Professor of Institutes of Medicine and Medical Jurisprudence in Jefferson Medical College. Philadelphia: P. Blakiston, Son & Co., 1884. Pp. 5 to 56, inclusive. [Price, \$1.]

Statistics of Four Hundred Cases of Rheumatism, etc. By Charles H. May, M. D., etc. [Reprint from the "Medical Record."]

Galvanic Batteries in Medicine, with Description of a New Selector. By Drs. Julius Rudisch and George W. Jacoby. [Reprint from the "Journal of Nervous and Mental Disease."]

Sixth Annual Report of the State Board of Health of the State of Connecticut, for the Fiscal Year ending November 30, 1883.

Quarterly Report of Medical Officers, United States Army, with their Stations and Duties, as reported to the Surgeon-General April 1, 1884, or at date of last report received at this office.

Report of the New York Hospital Saturday and Sunday Collection of 1883, together with a Sketch of the Association, its Objects and Results.

Seventieth Annual Report of the Trustees of the Massachusetts General Hospital and McLean Asylum, 1883.

Transactions of the New York Medico-Chirurgical Society, 1883.

Aneurysm of the Femoral Artery, and a Knife-Wound of the Intestines. By W. O. Roberts, M. D., Professor of Surgical Pathology and Operative Surgery in the University of Louisville. [Reprint from the "American Practitioner."]

The Effect of the Inundations of the Mississippi River upon Health. By R. H. Day, M. D., Baton Rouge, La. [Reprint from the "New Orleans Medical and Surgical Journal."]

Notes on the Opium Habit. By Asa P. Meylert, M. D., etc. New York: G. P. Putnam's Sons, 1884. Pp. 36.

First Annual Announcement of the Hahnemann Medical College, of San Francisco. Session of 1884-'85.

NEW YORK, SATURDAY, MAY 17, 1884.

THE ALCOHOL QUESTION.

Two aspects of the problem presented by the action of alcohol on the system have lately been under discussion in a somewhat prominent form abroad. The first relates to the matter of State control of inebriates, on which subject Dr. H. C. Tweedy read a paper at a recent meeting of the sub-section of State medicine of the Academy of Medicine in Ireland, an abstract of which we find, together with the discussion, in the "Dublin Journal of Medical Science." Beseet as it was with obstacles, chiefly the deep-rooted prejudice against any form of interference with the liberty of the subject, and wide-spread incredulity as to the efficiency of the measure, the idea of the State control of inebriates had been steadily gaining ground, Dr. Tweedy stated, ever since it was first broached, in 1855. He looked upon dipsomania as a form of insanity, involving a slow but sure course of self-destruction, practically a species of suicide, and against such a process the State had a right to interfere, to say nothing of the subservieney of individual rights to the general good. As to the objection that the power to incarcerate inebriates afforded unprincipled persons an opportunity of putting troublesome relatives out of the way, the danger was no greater for an inebriate than for a lunatic, and it was exceedingly improbable that two medical men of integrity would lend themselves as accomplices to such a fraud. It seems that the present law of the United Kingdom requires the consent of the drunkard to be obtained before he can be committed to a "retreat"; there is no provision for the detention of paupers; and the Habitual Drunkards' Act of 1879, under which commitments are made, is limited in its operation to a period of ten years, the consequence of which is an absence of any inducement for private enterprise to be directed to the founding of retreats. These defects in the law Dr. Tweedy would have corrected, and he urges an early resort to treatment, with a continuance of the detention until a cure is effected, or at least for a period of twelve months.

In the discussion, Dr. Henry Kennedy remarked that in the results reported from America he had not heard of any positive cures, and it was conceded that the number of cures was considerable, amounting in fact to none at all except when treatment was undertaken very early. The argument, so often brought up, that a very large percentage of crime was the result of intemperance, was criticised by Dr. Cameron, who remarked that no doubt it often happened that drunkards were thieves, and robbers, and murderers, but it was simply a coincidence that a man who was a robber, a burglar, or a murderer should also be a drunkard. That seventy-five per cent. of the persons committed to prison drank, he added, was highly proba-

ble, but it was equally probable that seventy-five per cent. of those not committed to prison drank too.

The other aspect of the matter of the relations of alcohol to public health to which we allude concerns the question of the elimination of the drug from the system or its assimilation. Under the heading "Is Alcohol a Food?" an editorial writer in the "Gazette hebdomadaire de médecine et de chirurgie" gives a critical summary of a discussion that was lately held in the *Académie de médecine* by M. Dujardin-Beaumetz and M. Maurice Perrin. The former took the ground that alcohol was in some degree an aliment, while the latter maintained that it simply passed through the system unchanged, being wholly eliminated by the skin, the kidneys, and the lungs. For obvious reasons, the writer in question remarks, M. Perrin has not been able to recover all the alcohol administered to animals experimentally, but he has been able to show the fallacy of those who attribute its excretion as such to the fact of its having been taken in amounts in excess of the assimilative power, for he has found it in the pulmonary, the renal, and the cutaneous exhalations when only very small quantities had been ingested. Moreover, he has never found aldehyde in the blood or the viscera after the ingestion of alcohol, from which he concludes that the latter is not oxidized in its passage through the system; and, like Proust and Vierordt, he has found that taking alcohol decreases the exhalation of carbonic acid.

The acid breath of drunkards, it is true, attests the acidification of the alcohol exhaled, but there is reason to believe that this takes place not only in the stomach, but also in the mouth—in the latter both before and after its elimination by the lungs. To the criticism of those who object to the inference drawn from the diminished excretion of carbonic acid, and urge that alcohol, on account of its richness in hydrogen, is converted more into water and less into carbonic acid than the other hydro-carbons when taken into the system, the writer replies that the hypothesis is not in accord with observed facts concerning the elimination of alcohol. He suggests a point that was not brought out in the discussion, that of the influence to be attributed to the degree of dilution of the alcohol before its ingestion—the more it is diluted the more likely it is to be partly assimilated. Attention is called also to the interpretation of the pathological effects of the agent, and especially to the obesity of drunkards, cirrhosis of the liver, and fatty deposits in the heart, the muscles, etc., which have been explained without sacrificing the doctrine of the combustion of alcohol in the system, notably by a sort of asphyxia of the blood-corpuscles, a retardation of the processes of oxidation, and a storing of hydro-carbonaceous materials. But, in regard to these matters, the writer concludes, our knowledge is still very defective.

HYDROPHOBIA IN BIRDS.

HERETOFORE it has been commonly supposed that birds were proof against rabies, but M. Paul Gibier, as we learn from the "Union médicale," recently related before the French Academy of Sciences some interesting facts and experiments bearing upon the question. Having inoculated a great many birds without

any effect that could be construed as at all specific, and in many instances without any appreciable result whatever, it happened to him at last to observe, among a number of birds inoculated, a domestic fowl which was attacked, fifteen days after the inoculation, with a paresis of the lower limbs and of the extensor muscles of the neck. When the hen was set at liberty and frightened, she tried to escape, but, being unable to stand on her feet, could only drag herself along on the ground with the aid of her wings. When in her cage, she remained motionless, and seemed incapable of holding her head up, letting it fall forward slowly until the beak touched the floor. Then she would raise her head suddenly, and again let it fall; and this she repeated incessantly. These symptoms continued for several days, and it was supposed that the fowl would die, but one morning she was found to have recovered from her paralysis, and she survived.

Regarding this case as quite exceptional, M. Gibier thinks it legitimate to conclude that the microbion of hydrophobia is capable of pursuing its evolution in the nervous tissue of birds, being finally eliminated without having given rise to lesions incompatible with life. This inference he founds on the fact that the brain of an inoculated bird is capable of conveying the disease to other animals by inoculation, but he has not yet tried inoculation from bird to bird, nor has he ascertained if one inoculation confers immunity against subsequent inoculations. The settlement of these points he looks upon as likely to throw a good deal of light on the nature of the disease, and perhaps to be of service in leading to a system of preventive inoculation of the human subject, resting this hope, apparently, on the idea that successive inoculations of birds will result in a mitigation of the disease. It must be conceded that the course of investigation undertaken by M. Gibier is one of great interest.

THE ALLEGED DETERIORATION OF THE PURITAN STOCK.

THAT figment of the imagination, the physical degeneracy of the American people, is a favorite topic with many well-meaning persons, and, although we can not help thinking that their uniform success in showing, all unconsciously, the fallacy of the assumption with which they set out is owing to their having thought of the subject superficially and from a prejudiced point of view, it must be admitted that the practical suggestions they are moved to make, with a view to avoid the continued action of the causes that they fancy to be keeping up the process they have pictured to themselves, are often of the greatest value.

With writings that seem to be open to this interpretation we must class a pamphlet, by Dr. John Ellis, entitled "Deterioration of the Puritan Stock, and its Causes." The author rests his inference as to the physical degeneration of the native population of Massachusetts chiefly on the comparative infecundity of the women—a circumstance which his own arguments go far to show to be wholly unconnected with degeneracy of a physical sort, even if we were to accept fecundity as the touchstone of vigor. This *non sequitur*, however, does not in the least detract from the wholesomeness of Dr. Ellis's

arraignment of the women of Massachusetts (or, for that matter, of both the women and the men of other parts of the country) for their neglect of the most obvious rules of correct living from a physical point of view. The reader who can make allowance for the irrelevance of this much of the argument, and can also stomach the long digression bearing upon the teachings of Swedenborg, will be both instructed and profited by studying the pamphlet.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

LAST year we expressed our high appreciation of the Association's meeting for the year 1883, and now we have to chronicle another annual gathering that may fairly be said to have been equally profitable. More papers were prepared for the meeting than for any other which the Association has held—except that of last year, and the papers were of a high order of merit. We are happy to be able to announce to our readers that, by an arrangement with the Association, we shall publish all of them in full, together with the discussions. Besides the formal papers, a great number of new instruments were presented, and they were of unusual merit, showing decided ingenuity and originality of design. It was thought that a new nomenclature would be presented for discussion, but it was not brought up. Important as such a matter is, and interesting as it is to laryngologists, if anything had to be omitted, it was certainly wise to let the nomenclature lie over.

Apart from its scientific aspect, it is gratifying to learn that the material interests of the Association are in a satisfactory condition, the financial statement having shown that the organization was free from debt. Although the meetings are not held at any one fixed place, the Association has a library, and is making an effort to collect the literature pertaining to laryngology. It may be within the power and the inclination of many of our readers to aid in this undertaking, and we are assured that any gifts to the library, either in the form of books, of pamphlets, or of periodicals devoted to the specialty, will be thankfully received. They may be sent to the librarian, Dr. Thomas R. French, No. 469 Clinton Avenue, Brooklyn.

MINOR PARAGRAPHS.

A "COLLECTIVE INVESTIGATION" BY THE STATE BOARD OF HEALTH.

A QUESTION of great practical moment often arises after the recovery of a patient from an attack of one of the infectious diseases, that, namely, of the length of time that must elapse before it is safe to allow the convalescent to go about again among the people at large—in other words, when the patient *per se*, setting aside the consideration of the matter of fomites, ceases to be capable of conveying the infection. We are glad to see that the secretary of the State Board of Health, who finds that local health officers and school trustees are often puzzled by the question, has issued a circular letter of inquiry to a number of prominent hospital physicians and teachers, asking them to give the board the results of their observation of facts bearing upon the question as regards small-pox, diphtheria, scarlet fever, measles, whooping-cough, and typhus.

In view of the great practical utility of such an inquiry, we trust that those whom the secretary has addressed will respond

promptly and fully to his queries; and it seems to us desirable, indeed, that some discussion of the matter should be had also in a more public way than would be involved in the mere relation of personal experience in the shape of communications to the board of health.

INDIGENOUS MEDICINAL PLANTS.

THERE can be no doubt that the botany, the chemistry, and the pharmacy of the medicinal plants of this country need to be investigated more fully than those of most of them have been investigated heretofore; or that the results of intelligent studies in this field should be brought widely to the knowledge of the medical profession. We trust that much may be accomplished in these directions through the medium of a new quarterly publication, entitled "Drugs and Medicines of North America," edited and published by Messrs. J. U. and C. G. Lloyd, of Cincinnati. The first number, dated April, 1884, deals with *Clematis virginiana*, *Thalictrum dioicum*, *Thalictrum anemonoides*, *Anemone nemorosa*, and *Anemone patens*, a considerable amount of space being given to the last-named plant, which is the American pulsatilla. A peculiar feature of the publication is that it gives the views of prominent representatives of the three leading "schools" of medicine, and it is announced that the next number will contain contributions from Professor Roberts Bartholow, Professor E. M. Hale, and Professor J. M. Scudder.

NEWS ITEMS, ETC.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending May 13, 1884:

DISEASES.	Week ending May 6.		Week ending May 13.	
	Cases.	Deaths.	Cases.	Deaths.
Typhus	2	0	9	3
Typhoid Fever	12	5	10	4
Scarlet Fever	82	18	80	17
Cerebro-spinal meningitis ..	5	4	4	3
Measles	106	20	131	17
Diphtheria	39	24	48	18
Small-pox	0	0	1	0

THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.—We learn from the "Centralblatt für Gynäkologie" that papers are expected to be read, or discussions held, on the following subjects in the *gynecological section*: Antisepsis in laparotomy; narcosis in laparotomy; early ovariectomy; laparotomy for fibrous tumors of the uterus; oöphorectomy for fibrous tumors of the uterus; oöphorectomy for nervous and psychical affections; vaginal extirpation of the cancerous uterus; dilatation of the uterus; the operative treatment of prolapse of the uterus and vagina; ovulation and menstruation; the operative treatment of extra-uterine pregnancy; on a uniform obstetrical nomenclature; the significance of albuminuria gravidarum; the treatment of abortion; the management of the placental stage of labor; anesthesia in childbirth; the treatment of rupture of the uterus in labor; the treatment of neglected transverse presentations; the Cæsarean operation and its substitutes; the statistics of puerperal fever in Denmark, Norway, and Sweden.

THE INTERNATIONAL CONGRESS OF HYGIENE will hold its fifth annual session at the Hague, August 21-26, 1884.

THE LOUISIANA STATE MEDICAL SOCIETY will hold its sixth annual meeting at Baton Rouge, beginning Wednesday, May 21st. The secretary gives notice that business of great importance concerning State legislation and proposed changes in the society's constitution renders a full attendance desirable.

SOPHISTICATED COFFEE.—It is reported that the sanitary officials of Brooklyn recently took some specimens of coffee beans from an establishment where they were undergoing a process of polishing, and, on chemical examination, found them dangerously contaminated with lead; whereupon Health Commissioner Raymond summoned the persons engaged in the business to appear before him for a hearing on the 12th inst.

RECENT PARIS THÈSES.—The following "Thèses de Paris" are mentioned in recent numbers of the "Progrès médical": Phenic Acid in the Treatment of Secretory Affections of the Eye, by M. Denis; A Study of Certain Points in Experimental Meningo-myelitis, by M. Dagonet; Solid Tumors of the Mediastinum, by M. Bertrand; The Preventive Treatment of Lymphangitis and Abscess of the Breast during Lactation, by M. Ressein; Certain Accidents of Growth—the Osteo-myelitis (Growth-Fevers), by Mrs. Agnes Lowry; Intestinal Hemorrhages in Typhoid Fever, by Miss Isabel Lowry; Lupus and its Relations with Scrofula and Tuberculosis, by M. Renouard; On a New Theory of the Cheyne-Stokes Respiratory Phenomenon, by M. Piaggio; Paralysis of the Sciatic Nerve of Pelvic Origin (their Pathology), by M. Dorcon; A Contribution to the Study of Ocular Affections due to Small-pox, by M. Tourneau.

THE "ARCHIVES OF PÆDIATRICS," heretofore published by its editor, Dr. W. P. Watson, of Jersey City, is to be issued in the future from the New York office of Messrs. J. E. Potter & Co., of Philadelphia. This change must be taken as a sign of the prosperity of the "Archives."

THE NEW YORK POLYCLINIC.—Dr. Thomas A. McBride has been elected a professor of diseases of the mind and nervous system. We congratulate the school on the fitness of this selection.

THE FRENCH ASSOCIATION FOR THE ADVANCEMENT OF THE SCIENCES will hold its thirteenth annual meeting at Blois, from the 4th to the 11th of September, 1884.

PROFESSOR MILNE-EDWARDS, according to the "Union médicale," has been made an officer of the Legion of Honor.

THE COLLEGE OF PHYSICIANS AND SURGEONS held its seventy-seventh annual commencement at Steinway Hall on Tuesday afternoon, the 13th inst. The new president, Professor John C. Dalton, occupied the chair for the first time on such an occasion. The Rev. Sullivan H. Weston, D. D., officiated as the chaplain of the college, and the Rev. Howard Crosby, D. D., delivered the address to the graduating class. The degree in medicine was conferred upon one hundred and five gentlemen. Dr. W. H. Draper, the president of the Alumni Association, announced the award of the alumni prize of \$500 to Dr. Moses Allen Starr, of the class of 1880. Dr. John G. Curtis, the secretary of the faculty, announced the awards of the Harsen prizes and the faculty prizes.

THE MEDICAL SOCIETY OF NORTH CAROLINA will hold its thirty-first annual meeting at Raleigh on Tuesday, the 20th inst. At the same time and place the State Board of Medical Examiners will examine applicants for license.

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.—The sixth annual session was held in New York on Monday, Tuesday, and Wednesday of this week, and the programme announced in our last issue was substantially gone through with. The papers, with the discussions upon them, will be published in full in this journal. The following-named gentlemen were elected officers for the ensuing year: Dr. E. L. Shurley, of Detroit, president; Dr. J. H. Hartman, of Baltimore, first vice-president; Dr. William H. Daly, of Pittsburgh, second vice-president; Dr. D. Bry-

son Delavan, of New York, secretary and treasurer; Dr. Thomas R. French, of Brooklyn, librarian; Dr. Frank Donaldson, of Baltimore, and Dr. F. H. Bosworth, of New York, new members of the council. The next meeting will be held at the call of the council.

THE NEW LABORATORY BUILDING FOR THE BELLEVUE HOSPITAL MEDICAL COLLEGE will be begun on the 7th of June, and it is expected that it will be completed late in the autumn. It is to consist of a front and rear section, connected with each other by a corridor. The front section will be devoted to laboratories, while the rear section will contain a large auditorium, to seat four hundred students, together with the museum and the library. Light-shafts will be arranged in the corridor. The museum is to contain specimens in pathological anatomy, for microscopical sections and for demonstrations in the class-room and the laboratory. The library will be devoted to books, pamphlets, and periodicals relating to pathological anatomy and histology, and it is intended to make it the most complete of its kind in the country. The faculty-room, the private rooms, and the lavatories will be arranged on the first floor. The stairs will be twelve feet wide. There will be accommodations in the cellar for the animals kept for experimental purposes, including a frog-pond, dog-kennels, and pens for rabbits, guinea-pigs, etc. Here also there will be a crematory. We are glad to learn that subscriptions for the necessary funds are coming in satisfactorily, the sum of \$5,000 having been given for apparatus alone. As we mentioned last week, the site of the building is to be in East Twenty-sixth Street, near First Avenue.

THE NEW YORK CANCER HOSPITAL.—The corner-stone of the hospital building will be laid this afternoon, Saturday, May 17th, at four o'clock. The site purchased for the hospital is a plot of ground, 180x200 feet in dimensions, on Eighth Avenue, between 105th and 106th Streets, facing the Central Park. We understand that the work will proceed rapidly. The fund, including Mr. John Jacob Astor's handsome gift of \$200,000, now amounts to \$375,000.

A FEMALE MEDICAL MISSIONARY.—Miss Sarah L. Weintraub, a native of Jerusalem, and a graduate of the Women's Medical College, of Philadelphia, left the country recently, for the purpose of doing duty as a medical missionary at Damascus, where her services will be given to the Arab women, whom the customs of the country debar from the attendance of medical men.

THE LATE DR. SAMUEL D. GROSS.—After the incineration of Dr. Gross's remains, the ashes were interred in the Woodlands Cemetery, Philadelphia. It is understood that the Jefferson Medical College will establish a chair of pathological anatomy in his honor, to be known as the Gross professorship, and that the American Medical Association will erect a statue to his memory.

THE OREGON STATE MEDICAL SOCIETY will hold its eleventh annual meeting at Portland, Tuesday, Wednesday, and Thursday the 27th, 28th, and 29th inst.

A "LIGHTNING TOOTH-PULLER," or "king of pain," as he is variously styled, is reported to have undertaken the removal of a tumor from a man's head recently, in Troy. He succeeded in tearing the growth away, but the patient died in the course of a few days, and since that time the "king of pain" has not been accessible.

ARMY INTELLIGENCE.—*Official List of Changes in the Stations and Duties of Officers serving in the Medical Department, United States Army, from May 4, 1884, to May 10, 1884:*

WEBSTER, WARREN, Major and Surgeon. Granted leave of

absence for six months, from April 29, 1884, on account of sickness. Par. 5, S. O. 103, A. G. O., May 3, 1884.

STEENBERG, GEORGE M., Major and Surgeon. Now at Governor's Island, New York Harbor, ordered to repair to this city (Washington, D. C.), to represent the Medical Department of the Army at the annual meeting of the American Medical Association, to meet on May 5, 1884, and, on adjournment of the Association, to return to Governor's Island. Par. 2, S. O. 103, A. G. O., May 3, 1884.

NAVAL INTELLIGENCE.—*Official List of Changes in the Medical Corps of the Navy during the Week ending May 10, 1884:*

GRAVATT, C. W., Passed Assistant Surgeon. Detached from Naval Hospital, Chelsea, and ordered to U. S. S. Michigan.

HARMON, G. E. H., Passed Assistant Surgeon. Detached from the Michigan and granted leave of absence.

EDGAR, J. M., Assistant Surgeon. Ordered for examination preliminary to promotion.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, May 19th:* New York County Medical Association; Medico-Chirurgical Society of German Physicians; Roman Medical Society (private).

Tuesday, May 20th: Medical Association of Central New York (Syracuse—annual); New York Obstetrical Society (private); Medical Society of the County of Kings; Ogdensburgh, N. Y., Medical Association.

Wednesday, May 21st: New Jersey Academy of Medicine (Newark).

Thursday, May 22d: Harlem Medical Association (private).

Friday, May 23d: New York Clinical Society (private); Yorkville Medical Association (private); New York Society of German Physicians (private).

Saturday, May 24th: New York Medical and Surgical Society (private).

OBITUARY NOTES.

PROFESSOR C. A. WURTZ.—It was only last month that Professor Dumas died, and now a press dispatch announces the death of Professor Charles Adolphe Wurtz, another eminent French chemist. For a number of years he was the dean of the medical faculty of Paris, at various times he taught chemistry in several institutions, and he was the author of many contributions to the literature of that science.

DR. URIAH H. HOLBROOK, OF PROVIDENCE, R. I.—Dr. Holbrook died May 8th, after a long illness, at the age of thirty-four. He was a graduate of Brown University and of the Harvard Medical School, and had been in successful practice for about eight years.

Letters to the Editor.

THE STATE SOCIETY'S COMMITTEE ON LEGISLATION.

NEW YORK, April 12, 1884.

To the Editor of the New York Medical Journal:

SIR: In the issue of your journal of the 12th inst., in the discussion on the subject of the College of Midwifery, Dr. Piffard is reported as saying that "the impression had gone out through the medium of the 'New York Medical Journal' that it was the duty of the Committee on Legislation of the Medical Society of the State of New York to take action to prevent the passage of a bill relating to the establishment of a certain college of midwifery in this city, and the regulation of the practice

of midwifery in this State. That bill, as was well known, had many very objectionable features, and it was a duty of the profession to the public to have it defeated. But it was a mistake to suppose that the Committee on Legislation of the State society should assume this responsibility. That committee had too much to attend to already, and had not been furnished with means to enable it to assume and execute further work."

Let us see if this supposition is a mistake, or whether the mistake is not with the Committee on Legislation.

A short time since I wrote a letter to the secretary of the State society asking him what were the duties of the Committee on Legislation of the State society, which elicited the following reply:

"7 MYERS BLOCK, SYRACUSE, N. Y.,
"February 27, 1884.

"F. R. STURGIS, M. D.

"DEAR DOCTOR: In reply to your inquiry as to the functions of the Committee on Legislation, I copy the by-law on the subject (see Trans., 1880, appendix, p. 10, sec. 5). 'There shall be a standing committee on legislation, consisting of three members, the duties of which shall be to watch the course of State legislation on medical subjects and to take charge of such matters pertaining to medical legislation as shall be referred to them by this society, and all resolutions touching medical legislation shall be referred to this committee, which shall make a report thereon to this society as soon as possible. It shall also at each annual meeting report to the society any laws relating to medical matters that may have been passed within the year.'

"The watching the course of State legislation on medical matters was, at the time of the adoption of the by-law, considered one of the most important duties of this committee. The watching includes, I take it, the putting forth all proper efforts to prevent the passage of laws detrimental to the interests of the medical fraternity, and also, as seems to me, the helping on of all medical legislation that is plainly for the welfare of the profession. The main object had in view was the *defeating of all bad medical legislation*, as I remember the matter."

This seems to me plainly what the committee is appointed for. The mere watching of bills is of no service if the committee is to do nothing to oppose bad or to assist good legislation. That the committee has its hands full I can well understand, and succeeding committees are likely to find the same thing true, but that is no excuse for neglecting to attend to the interests of the profession in this State, nor is the plea that it has no money to expend for the execution of further work. The committee should have asked for means to carry out the work which it is its duty to attend to. The society would, I believe, have appropriated funds for that purpose.

Yours very truly,
F. R. STURGIS.

NAIL-BITING AND HEART DISEASE IN CHILDREN.

MONTICELLO, IND., May 8, 1884.

To the Editor of the New York Medical Journal:

SIR: I desire to call the attention of the medical profession to a peculiar symptom I have noticed in three cases of valvular disease of the heart in children.

The patients were all females, aged nine, ten, and thirteen years, and each was affected with mitral insufficiency, which was produced by rheumatism. The peculiar symptom or habit to which I refer is biting the finger-nails off very close on each hand.

Each patient, when her attention is not called to something else, constantly keeps one hand or the other near the mouth and bites off the nail of each finger as far down as possible.

I would like some physiologist to explain the pathology of the habit.

It is a question with me whether or not there is any connection between the heart trouble and the habit.

I desire all members of the profession who may read this card to examine their patients who have valvular disease of the heart and notice whether or not they are addicted to this habit. I have never noticed it in adults who have valvular disease.

Yours truly,
R. J. CLARK, M. D.

Proceedings of Societies.

NEW YORK ACADEMY OF MEDICINE.

Meeting of May 1, 1884.

HORACE T. HANKS, M. D., Vice-President, in the chair.

A MEMOIR OF THE LATE DR. EDWARD L. BEADLE was read by DR. JOHN G. ADAMS. Among Dr. Beadle's most prominent characteristics was a well-balanced mind, combining with wisdom great prudence and self-control, and charity toward all men. He threw all his influence on the side of right. He was severely just, inflexibly honest, and had the intense courage of his convictions; he was wise in counsel, endowed with executive ability, great in goodness, great in beneficence, genial, loving, a great-hearted man. The memorialist recounted in a vivid manner the numerous duties performed and places of responsibility held by Dr. Beadle. More than half of his estate was left to benevolent institutions; liberal donations had been made to the Academy, and five thousand dollars were bequeathed to it in his will.

STUDIES IN ENDOMETRITIS.—DR. M. PUTNAM JACOBI read a paper in which she spoke of the utero-ovarian system as made up essentially of the endometrium and the cortex of the ovary, which were physiologically continuous. Together, these tissues constituted an organ which might be called the germinating membrane. This system underwent certain cyclical changes, which she spoke of as the greater and the lesser, the former connected with pregnancy, the latter with menstruation. The characteristic disease of the greater cycle was subinvolution, including both the uterus and the parametrium. Disease arising from the lesser cycle, endometritis, was analogous to the former, and consisted in a subinvolution of the endometrium. Nearly all other utero-ovarian diseases might in like manner be traced to disease of this so-called germinating membrane: perimetritis and parametritis, resulting from inflammation of its lymphatics, or irritation of its vascular radicles; softening of the uterine stem, the natural consequence of catarrh; versions, due to atrophy or want of innervation of the uterine supports; oöphoritis, always secondary to fundal endometritis, etc. Utero-ovarian diseases, therefore, were due to a deviation of the process of growth proper to the utero-ovarian tissue. The most ordinary aspect of this deviation was called inflammation, and occurred during the active period of cyclical development. For both the success and the safety of local treatment of endometritis, it was essential to take into account the local rhythmic changes of which the utero-ovarian system was the seat. Applications, if used, should be made to the endometrium shortly after menstruation, and, if made twice during the month, the second application should be made not later than the tenth day after the cessation of a period. She was persuaded that in the perfectly normal condition the weight of the uterus was not increased during menstruation. She did not believe there was congestion of the substance of the uterus, or increased development of structure, as commonly taught. Antelexion she regarded as due to reflex nerve irritation in the round ligament, originating

in an endometritis; posterior displacements were due to relaxation of the ligaments of support, from atrophy or want of proper innervation due to the same cause. In prolapsus there was complete absence of innervation of the uterine supports. Effectual treatment lay in re-establishing the normal physiological conditions of the utero-ovarian system, which could not be expected to take place from the mere use of pessaries. Some cases would be cured with proper exercise, gymnastics, massage, and improved hygiene; others would be found completely relieved by a single application to the endometrium. The object of intra-uterine applications was the ultimate destruction of the sub-involved portion of that membrane. No application should be made with the idea of producing an astringent effect, as the mucous membrane of the uterus, like a new growth—a nevus, for example—was not susceptible of being a-tinged. An indirect benefit attending the applications was the reflex stimulus which they imparted to the neighboring diseased structures. The author spoke of the dangers of intra-uterine applications, and especially of the use of tents; in some conditions she would employ carbolic acid and iodine; but these remedies should not be so universally used as it seemed they were. Iodine, especially, was an irritant. Particular attention was directed to the necessity of preventing or curing endometritis, upon which so great a variety of pathological conditions depended, and of attention to the cyclical changes in directing local treatment. Ovarian pain before menstruation was commonly due to changes in the fundus of the uterus, and might be relieved by applications to the fundal endometrium. Many symptoms, usually regarded as ovarian, or as due to disease of the cervix, were really due to disease of the fundus. On account of the reflex or propagating influence, however, of remedies applied to the cervix, benefit might be given to the diseased membrane of the fundus.

Dr. PAUL F. MUNDÉ was glad to hear the point brought out so clearly that there were two conditions which were accountable for endometritis, namely, menstrual subinvolution and puerperal subinvolution. That a large proportion of cases were due to this cause, subinvolution, was evident from the large size of the uterine canal so often present. He was also convinced that a large proportion of cases of pelvic cellulitis and pelvic peritonitis were due to extension of irritation from the endometrium, and that, to remove the tendency to recurrence of these inflammations, we must remove the endometritis. He also indorsed the ætiology of uterine displacements which the author had given; but in versions he thought that the heavier the fundus the more likely were they to occur. As to the prognosis, it was not very promising; usually we could only palliate, or produce a temporary cure. He agreed with the author that the cyclical change should be observed in making applications, and that they should not be repeated too frequently. He was not opposed to strong applications, and he had seen benefit from the curette.

Dr. W. GILL WYLIE thought that, if endometritis proved to be incurable, it was due to the fact that the disease had involved the Fallopian tube, and this, being tortuous, when distended with secretions, contained irritating matter which poured over the mucous membrane of the uterus. He believed that intractable endometritis was very frequently due to specific disease, to gonorrhœa, which so often gave rise to salpingitis. Local treatment was apt to prove dangerous, and he thought it wise always to give the patient about six weeks' rest in the active stage before making local applications. He had obtained special benefit from a small tampon soaked in glycerin introduced up to the cervix; afterward, adding alum to make it strictly antiseptic, iodoform was dusted on, and, if he used a tent to produce dilation, this also was rendered antiseptic with iodoform. He thought applications were commonly made too frequently.

BUFFALO MEDICAL AND SURGICAL ASSOCIATION.

Meeting of May 6, 1884.

F. W. BARTLETT, M. D., President, in the chair.

THE PRESIDENT appointed Dr. M. Hartwig, Dr. M. D. Mann, and Dr. C. C. F. Gay as the Finance Committee for the ensuing year.

THE USE OF THE OPHTHALMOSCOPE IN GENERAL MEDICINE.—Dr. LUCIEN HOWE spoke on this subject, illustrating his remarks with charts, drawings, and a magic lantern, and exhibiting a number of patients. He said the ophthalmoscope was an essential aid in diagnosis, and especially in kidney disease, and believed it to be as necessary as the microscope. There was really no difficulty in making an examination of the retina, if we took care to have the eye, the light, and the observer in one line. Here he illustrated the position to assume, and exhibited several instruments. He then entered into a detailed description of what one should see in retinitis albuminurica, lucæmia, and syphilitica. The amount of albumin was not always a guide to the diagnosis of renal affections, but retinitis was almost certain to be found in some degree. Syphilis showed itself both in the retina and in the choroid. Albuminuria was much more frequent in pregnancy than many imagined, and this form of retinitis would readily assist in the diagnosis. Dimness of vision was discovered in the course of the pregnancy, and even permanent blindness might result. Dr. Howe related several interesting cases as examples. In such cases the retinitis might become so severe as to call for the induction of premature labor to save the patient. We recognized also a form of retinitis in diabetes, for that disease did not manifest itself in the eye in cataract alone.

Dr. HARTWIG thought Dr. Howe was correct in saying that general practitioners should understand this instrument. The medical colleges should teach the use of it, and in Germany they were now beginning to require a knowledge of ophthalmoscopy of candidates for the medical degree.

Dr. HUBBELL thought that much more might have been added concerning diseases upon which this instrument threw light, especially obscure difficulties of the brain—such as tumors—and diseases of the spinal cord. It was an instrument sufficiently simple in its principles, and both the ophthalmoscopic and the otoscopic mirrors should be brought into more general use.

Dr. MARY B. MOODY mentioned a case that had been sent to Dr. Noyes, of New York, with loss of vision in one eye. The patient was returned to the city to be treated for a rheumatic deposit in the eye, and with a prescription for citrate of lithium, under which there was great improvement. She would like to ask Dr. Howe to explain this condition.

Dr. HOWE responded that the iris only was affected in rheumatic difficulty, and not the retina.

Dr. CROSVY did not know that doctors would ever cure their albuminuric patients because they discovered a retinitis albuminurica; but, if a patient had dimness of vision, by the use of the ophthalmoscope the physician might be led to examine the urine. Perhaps numbers of those present had treated epileptics with bromide of potassium, some of whom recovered while others did not. By means of the ophthalmoscope, the two forms of epilepsy—the one depending upon anemia and the other upon plethora—could be distinguished, and, in consequence, the physician would know when to make use of the bromides and when of iron. He had read recently of a case in which there were strange vacillations of vision and variations in sight, where the ophthalmoscope assisted in the diagnosis of a tumor. The blindness in cases of puerperal albuminuria was illustrated by a remarkable case of his own. It was found that the patient had

had a little dimness of vision in her first and second pregnancies. In her third, for which he was called at the eighth month, he found her perfectly blind, and, to ward off convulsions, he induced labor at that period. She recovered well from this, and was in pretty fair health, but died, at the end of three months, from Bright's disease.

Dr. KING thought a wide field was opened for the ophthalmoscope in the diagnosis of syphilitic and albuminuric diseases.

THE PRESIDENT remarked upon the advances we were making in instruments of precision.

Dr. HOWE said he would like to mention a case of brain complication. He had seen a boy, with Dr. Mynter and Dr. Diehl, who had incipient retinitis, with paralyses of the third and sixth nerves, and difficulty with the sense of smell. He prognosticated a loss of sight, hearing, and smell, and the case had so resulted. At this time the boy's only means of receiving impressions from the outer world was the sense of touch. He would say to his mother, "Shake my leg when the doctor comes." Dr. HOWE made a diagnosis of tumor in a certain convolution, and found it, at the post-mortem examination, exactly in that location. He said it was out of the question to diagnose cerebral hyperemia with the ophthalmoscope, as much so as to diagnose the condition of the meninges through the ear.

Dr. HARTWIG asked how Dr. HOWE would account for such a case as this—viz., a person becoming completely blind for twenty-four hours and then suddenly recovering his vision perfectly.

Dr. HOWE thought it might be due to an infiltration of serum.

Dr. CRONYN suggested its being a form of edema fugax, which Dr. Hartwig accepted as a good explanation.

MAMMARY DEVELOPMENT IN THE MALE.—Dr. HARTWIG had seen a man lately with one developed breast. It felt in every way like a woman's breast. It was not a tumor, for the man had had it all his life. It was not adipose tissue, for he was emaciated. Hyrtl cited a case, in his "Anatomy," of a man sucking his child.

Dr. CRONYN said it was a common practice in India for men to nurse the children, as reported by Dr. O'Shaughnessy.

Dr. FRANK mentioned the case of a man he had seen lately with two large, pendulous mammae.

Dr. HARTWIG demurred to this, saying it was probably an unusually large deposit of adipose tissue. But Dr. FRANK was confident he knew the difference between male and female breasts.

Dr. PARK stated that it was the custom in Pomerania to train men as wet-nurses. He had lately seen an unusually interesting case of a supernumerary breast in the axillary region of a woman.

THE PRESIDENT'S ADDRESS.—The PRESIDENT read the following:

Entering upon the duties of another year, each and all of us are doubtless desirous that this association should, profiting by the experience of the past, enlarge its sphere of influence and usefulness, and continue to be the representative medical association of the city. Upon my accession to the chair I have but little to say beyond expressing my thanks for your kind consideration. The only suggestion that occurs to me at present is the conducting of some part of our work by means of sections. In most large medical societies two or more sections are recognized, and it seems to me that I rightly construe the signs of the times in recommending this departure. I should be glad to see four sections—viz.: medicine, surgery, obstetrics, and pharmacy—organized.

With reference to the working of such sections I have no personal experience, but doubtless many members of the association are familiar with details.

By our act of incorporation and by-laws, committees may be appointed to report upon any topic or subject, and, if the association is not ready to decide upon the feasibility of the plan proposed, I would like a committee appointed to report at our next meeting. The reports of the sections may be made at regular meetings or sub-meetings, and for the use of any or all sub-meetings for the year I tender my offices, if acceptable, without expense of any kind. They are so located as to be easily reached. The best evidence that we have reached a period in our history favorable to the proposition is the recent creation of special societies to discuss matters entirely germane to our own work. The promoters give evidence of a laudable ambition, and yet it seems to me that the work they undertake might be much better performed within our own association. I have thought, if these views favorably affect you, of proposing that each member be asked to intimate his preference as regards assignment to a particular section, and, when sections are established, each shall appoint its officers, dates of meeting, and the plan of its work.

By this course we concentrate instead of dispersing.

These remarks are intended merely to bring the subject before you. I shall very cheerfully assent to any plan that represents the wishes of the majority.

I am very desirous that the great body of regular physicians in Buffalo may be inspired to act harmoniously and industriously in advancing the interests and prestige of this association, which has existed nearly forty years and been honored by the membership of many of the most distinguished physicians of the country.

After some discussion by Dr. COAKLEY, Dr. FRANK, and Dr. CRONYN, a motion was finally carried that the President appoint a committee of five to consider his recommendation, he to serve as one of the members. The committee named for this purpose was as follows: President BARTLETT, and Dr. COAKLEY, Dr. CRONYN, Dr. HOWE, and Dr. KING.

REPORTS OF PREVAILING DISEASES.—Dr. MARY MOODY had seen and heard of several cases of puerperal fever.

Dr. CRONYN had had a great number of scarlet-fever patients, most of them with light symptoms, but a few of these with severe sequelae, such as dropsy and hæmaturia.

Dr. KING also reported the prevalence of scarlet fever of a mild type, and had observed a tendency to puerperal fever in his confinement cases.

THE PRESIDENT coincided with the other gentlemen in his observations of scarlet fever. He had seen very little diphtheria of late.

FREDERICK PETERSON, M. D., *Secretary*.

MEDICAL SOCIETY OF THE COUNTY OF KINGS.

Meeting of April 15, 1884.

THE PRESIDENT, Dr. JOHN A. MCCORKLE, in the chair.

THE DISABILITY IN DOUBLE, OR SIMULTANEOUS, FRACTURES OF THE PATELLE.—Dr. J. S. WIGHT read a paper with this title. [See p. 541.]

DOUBLE AMPUTATION OF THE ANTERIOR PART OF THE FEET, AFTER ERICHSEN.—Dr. WIGHT also read the histories of two cases of this sort. [See p. 543.]

In the discussion on Dr. Wight's first paper, Dr. G. H. ATKINSON remarked that, in his opinion, but few of these cases were reported, and he wished it were possible in this country to keep trace of such patients a sufficient length of time to enable one to see the results. He had had a case of double fracture of the patella, which was a refracture, the patient having been treated before by a surgeon on Long Island. The refracture was produced by the patient's rising suddenly from a kneel-

ing posture. The result of treatment was not satisfactory, there being a kind of ligamentous union, but not of sufficient strength to enable the patient to use the limbs freely. Another case had come under his observation, that of a baseball-player, who, while running down hill, slipped and fell in soft earth on his knees, fracturing both patellæ. He saw the patient but once, and the attending surgeon did not report the result.

Dr. WIGHT said that there might have been cases of double fracture of the patellæ the results of which were so unfavorable that they had not been reported. He had recently treated a case of fracture, nearly transverse, of the left patella, complicated by complete avulsion of the lower fragment from the tibia, or rupture of the ligamentum patellæ. The lower fragment was much displaced upward at the time of the injury. The result had been good; the bond of union between the fragments was about a quarter of an inch long, and the ligamentum patellæ had been quite well repaired.

Dr. J. H. H. BURGE remarked that Dr. Markoe had recently reported to the New York Surgical Society a case of simultaneous rupture of both quadriceps tendons, which had happened in the practice of Dr. Weir [see the "New York Medical Journal" for April 5th, p. 389]. It was three months since the accident, and the patient was able to walk slowly. Dr. Burge referred to the case as bearing upon the question of permanent disability. He thought there was likely to be a marked contrast in this respect between the cases of fractured patella and those of rupture of the tendon.

ANTISEPTIC SURGERY IN PRIVATE PRACTICE.—Dr. FRANK W. ROCKWELL read a paper with this title. [See p. 543.]

HOSPITAL ANTISEPTIC SURGERY.—Dr. GEORGE R. FOWLER then read a paper with this title. [See p. 546.]

The two papers being under discussion, Dr. FOWLER wished, at this early stage, to take exception to Dr. Rockwell's statement that his dressing was a modified antiseptic one. It was not; it was a thoroughly antiseptic one, and very efficient, and all the precautions adopted by him were in accordance with strict antiseptic rules and principles.

Dr. ROCKWELL thought his friend Dr. Fowler had slightly misunderstood his application of the word "modified." The dressing was modified simply in so far as it discarded the "protective" Macintosh and the cumbersome outer layers of gauze and cotton, at one time considered so essential to success. The naphthalin was so free from all irritating qualities that no protective was needed, the wound surface being directly in contact with the powdered drug; and the outer layers were done away with, as only enough gauze was needed to confine the vapor of naphthalin to the wound district and absorb the discharges if any occurred. He was thoroughly in accord with those who believed in strict antiseptics, though he thought the theory which considered germs only as the causes of danger was open to some practical objections. As to the spray, its total discontinuance was, he believed, a mere matter of time, as, with thorough irrigation of a wound with antiseptic fluids, it could be left in as safe condition as with the spray, and with far less trouble.

Dr. WIGHT had always been greatly interested in antiseptic surgery, but he wished to have it understood that, in his opinion, Listerism was not the whole of antiseptic surgery. He had been delighted to listen to the very able papers of Dr. Fowler and Dr. Rockwell; he wished to say, however, that he had treated cases side by side, with different forms of disease, without the application of Listerism, and these patients had had no rise of temperature. We must go back of the wound—to the foundation of all our researches, viz., to the cell. Feed the patient, give him milk-punch if necessary, and good, nourishing sustenance—feed the patient, and thereby the cells of the body,

to enable them to overcome the germs—or, rather, give the patient fresh air and appropriate food, to enable the somatic cells to resist the influence of the bacteria so far as possible; for antiseptic surgery was not altogether confined to local applications.

Dr. FOWLER said: "In listening to the remarks just made by Professor Wight, one is reminded of a story of the illustrious Valentine Mott. It is reported of him that, being invited to be present at the ligation of the femoral artery by a surgeon possessed of more confidence than skill, and seeing the operator at one fell swoop slash through skin, fascia, and underlying structures within the vessel's sheath, he exclaimed: 'God help the patient!' and immediately afterward, as he saw the vessel remain uninjured, 'God has helped the patient.' It seems to me that, in a similar sense, one may exclaim, when presented with facts such as we have just heard, 'God did help the patient.' No surgeon should think of going from a patient, in such a condition as has been described, to another suffering from an open wound; and, if, happily, such risk of infection is followed by no evil consequences, surely no one should follow such a precedent. Besides, under strict antiseptic treatment such conditions do not exist, and the surgeon may go from one patient to another, with antiseptic precautions, with no fear of being the bearer of poisonous material."

Dr. WIGHT, replying to Dr. Fowler, said that he had always taught all the nurses and *internes* to be scrupulously exact in regard to cleanliness, washing their hands in chlorine-water before going from one patient to another. To show what could be done without the antiseptic method, he related the case of a man, seventy years of age, who had a compound fracture of the left knee, with the bones sticking out. The wound was cleansed and dressed with cotton wool, sealing up the wound and effectually making the fracture a simple one. The man recovered without a single untoward symptom, and died six years afterward with Bright's disease. Antiseptic surgery was good, but the surgeon must keep his hands clean as he went to successive patients. He also related another case, that of a young man who had a small wound in his larynx, and who had careful antiseptic treatment. He died of pyæmia in a few days. He might remark that this young man had a most "inconsistent" physique, while the old man had a physical constitution remarkable for its powers of resistance.

Dr. ERNEST PALMER wished to call attention to the fact that Dr. Wight's patient was a man who had all his life been "soaked" in whisky, and therefore was in a totally antiseptic condition.

Dr. ATKINSON alluded to the story of the two valiant knights meeting and looking on the opposite sides of a pendent shield, one of them declaring it to be of silver, and the other of gold. After they had fought over the question for some time, a friend interfered, and showed each of them his error by turning the shield around. He would suggest a plan to harmonize the conflicting theories. He thought pressure on a wound was dangerous, forcing back into the tissue the products of the injury and inflammation. To him, there seemed less danger from sepsis from without than from within. He was glad to see the whole scheme portrayed which provided for the conveying away of those products of which he had spoken, as well as for affording protection from outside sepsis; and in the future he would use it. His criticism on previous methods was, that antiseptic dressing did not provide for carrying away the products of the wound or injury; hence, in a large number of cases, leading to more danger than it provided against. He would cite the cases, just read by Professor Wight, of amputation after sloughing from frost-bite, where the tissues were infiltrated, and the escape of discharges had to be provided for.

AMERICAN MEDICAL ASSOCIATION.

SECTION IN MEDICINE.

Dr. JOHN V. SHOEMAKER, of Philadelphia, Chairman.

Session of May 6, 1884.

THE SIMULATION OF PATHOGNOMONIC SIGNS AND SYMPTOMS was the title of a paper read by Dr. E. G. JANEWAY, of New York. He had been led to write it by the many mistakes caused by relying on the so-called pathognomonic signs. Snap diagnoses were very liable to lead to mistakes. Choked disc was at one time thought to be pathognomonic of cerebral tumor; we now limited it to an indication of increased intra-cranial pressure. Certain conditions of the retinal vessels were also relied upon as determining the state of the circulation within the brain—tremor as indicating multiple sclerosis, but, before this meaning can be attached to it, metallic poisoning and the effects of alcohol must be excluded. The significance of coma was often difficult to determine. Some asserted that in uræmia the temperature was elevated, others that it was normal. A lower temperature at the onset, with a subsequent elevation, is relied upon by the author as indicating cerebral hæmorrhage. Some would rely upon albumin and casts in the urine, but this might be misleading, for in cerebral hæmorrhage there was often renal disease. There was no reliable guide in distinguishing embolism from hæmorrhage. Heart symptoms might exist, and yet the case not be one of embolism, while, on the other hand, they might be absent, and yet the attack be one of embolism, the embolus coming from a clot outside of the heart. In some cases of fever there was rigidity of the muscles of the neck, and this might lead to the diagnosis of meningitis. Vocal fremitus could not be relied upon as distinguishing consolidation of the lung from pleural effusion. It might be present in the latter condition, and might even be intensified. Bronchial breathing was frequently present with pleural effusion. It was, however, usually found at the upper limit, and was somewhat sniffling in character. Sometimes it was so distinct that the best observers might be misled. The physical signs of a cavity might exist with the lung solidified or compressed by fluid. The writer drew attention to what he termed normal pectoriloquy. In heart diseases, it is supposed that murmurs heard over the heart were due to disease of the valves. This was not always true. The double arterial murmur was not always diagnostic of aneurysm, the writer having reported cases in which it was due to the pressure of a tumor. He then alluded to the great liability of mistaking the dyspnoea of Bright's disease for that accompanying cardiac troubles. Albumin sometimes occurred in the urine in healthy individuals, and hyaline casts might come from healthy kidneys.

Dr. DONALDSON, of Baltimore, thought there were points of distinction between the bronchial breathing of pleural effusion and that of pneumonia. In pleurisy it was more pronounced on inspiration than on expiration, and less harsh. It was not ordinarily heard at the commencement of the effusion. At least one third of the pleural cavity must first be involved. Serious lesions of the heart might not cause murmurs. This was preeminently true in excessive insufficiency of the mitral valve, the intensity of the murmur being inversely proportional to the size of the orifice. He could recall eleven cases of mitral stenosis uncomplicated by a murmur.

Dr. J. S. LYNCH, of Baltimore, referred to a case which he had seen a number of years ago in which bronchophony was associated with pleurisy. He explained its occurrence by the existence of adhesions between the pulmonary pleura and that of the diaphragm preventing compression of the lung.

Dr. JANEWAY stated that the bronchial breathing was heard near the top of the fluid in pleural effusion. The mistakes were made by not recognizing this peculiarity.

THE CLINICAL STUDY OF THE HEART SOUNDS.—Dr. AUSTIN FLINT, Sr., of New York, read a paper in which he divided the heart sounds into five distinct sounds, two of which were diastolic and three systolic. The diastolic sounds were the aortic and pulmonic. The systolic sounds were the mitral, the tricuspid, and the sound of impulsion produced by the impulse of the heart against the chest-wall. The booming character of the first sound was due to the impulse. This was heard with the greatest intensity at the apex. The mitral sound was heard a little to the left of the apex, while the tricuspid was heard to the right. He next considered the significance of alterations in the character of each of these sounds. Incompetency of the aortic valve was generally, if not invariably, represented by a regurgitant murmur. This simply showed incompetency without giving any idea as to the amount, which was to be determined from other points, particularly a comparison with the power of the left ventricle as shown by the sound of impulse. Abnormal increase in the intensity of the aortic sound was referable to two causes: 1. Increased power of the systole of the left ventricle. 2. Increased blood pressure in the systemic arteries. Experiments tended to show that increasing the blood pressure had no effect on the aortic sound. The intensity of the pulmonic sound was increased by increase of the blood pressure in the pulmonary arterial system. Insufficiency of the mitral valve was represented by a murmur which gave no information as to its amount. The sound of impulse furnished this. The sound of impulse was increased in cardiac hypertrophy, and diminished or absent in weakness of the ventricular systole. Alterations in the tricuspid sound were not of much importance, on account of the rarity with which this valve was diseased. Hypertrophy of the right ventricle intensified it.

Dr. F. C. SHATTUCK, of Boston, stated that many authors maintained that the muscular contraction was an important element in the formation of the first sound of the heart.

Dr. JAMES C. WILSON, of Philadelphia, referred to the fact that the Germans had for some time been following the plan suggested by Dr. Flint in the study of the heart sounds. He had himself been employing a similar plan, dividing the sounds into four instead of two. He would like to hear what Dr. Flint had to say in regard to the muscular contraction being one element of the first sound.

Dr. MCSHERRY, of Baltimore, spoke of the value of a study of the pulse, and contrasted our present knowledge of diseases of the heart with that of thirty years ago.

[At this point a telegram was received from Philadelphia announcing the death of Professor S. D. Gross. A motion to adjourn the meeting of the section was made. Before the question was put, Dr. AUSTIN FLINT, Sr., stated that he had been an intimate friend of Dr. Gross's for over thirty years, and he believed that Dr. Gross would be the last to wish the proceedings to be interrupted by his departure from this world. The motion was lost.]

Dr. LYNCH referred to the importance of alteration of the aortic sound in Bright's disease. He thought a large part of the booming character of the first sound was due to the vibration of the aortic walls at each systole. He could not understand why increase in the blood pressure in the large arteries should not increase the intensity of the aortic sound. Dr. Flint had stated that the intensity of the pulmonic sound was increased by increase of blood pressure in the pulmonary arterial system. Why should not the same result follow increased pressure in the systemic arteries?

Dr. GARLAND, of Boston, said it was often difficult to decide

whether a murmur was coincident with or replaced the cardiac sound. This was important to decide in diagnosis. He spoke of the importance of getting rid of the respiratory movements in trying to determine this point. A murmur would sometimes disappear when the breath was held for a moment. A deceptive murmur was sometimes heard at the base of the heart, to the right or the left of the sternum and up and down its border. It was systolic in time. The peculiarity of this murmur was that it disappeared on full inspiration.

Dr. DONALDSON thought it a question whether or not the impulse of the heart could produce a sound. Muscular contraction did not produce a sound, or at least not of sufficient force to be heard without very delicate instruments. Experiments had shown that the first sound was produced by the closure of the mitral and tricuspid valves. Where these had been prevented from closing, the sound had been absent. In regard to presystolic murmurs, Dr. Leaming, of New York, had stated with much plausibility that they were not really presystolic, but occurred at the beginning of the systole.

Dr. FLINT, in concluding the discussion, said that many of the points advanced referred to the mechanism of the sounds and murmurs. This he had not touched on in his paper, and therefore he waived any consideration of it at this time. His paper was concerned solely with the clinical aspects of the heart sounds. In regard to the Germans having taught the subject in the same manner as he did, he would call attention to the fact that twenty-six years ago he had pointed out this plan. He could not explain why the blood pressure acted differently in the pulmonary and systemic arteries, but such appeared to be the fact.

DERMATITIS HERPETIFORMIS.—In a paper with this title, Dr. LOUIS A. DUHRING, of Philadelphia, grouped a number of cases of a rare disease of the skin which he had met with from time to time, having some features in common with several well-known diseases, notably herpes, pemphigus, and eczema, but which, nevertheless, was distinct from these affections. It manifested itself by the formation of erythematous patches of an urticarial or erythema-multiforme-like character; variable-sized, irregularly shaped or stellate, flat or raised, more or less grouped herpetic vesicles; blebs of similar character; pustules, flat or acuminate, whitish in color, with a more or less inflammatory base; and papules, vesico-papules, and variously sized, circumscribed infiltrations, all the lesions inclining to assume an herpetic character (taking herpes zoster as the type of eruption), accompanied with violent itching. One or another of these varieties of lesions might be present as one, or, as often happened, they might appear together as a mixed or multiform eruption, or the several forms might succeed one another during an attack or as a subsequent relapse. The disease was remarkable for the multiformity of lesion. Thus it might be divided into the erythematous, papular, vesicular, bullous, pustular, and multiform varieties. This protean and multiform nature of the disease had been previously pointed out by the author, in the second edition of his treatise on "Skin Diseases," in considering the "impetigo herpetiformis" of Hebra, which represented the pustular variety of dermatitis herpetiformis according to Dr. Duhring. The erythematous variety bore some resemblance to urticaria, and especially to erythema multiforme, the variation in color and pigmentation calling to mind the latter affection; but the course of the disease was chronic, this variety usually giving way sooner or later to three forms of eruption. The vesicular variety was of more frequent occurrence, the lesions varying in size from a pin-head to a pea. They were usually flat, irregularly shaped, angular, glistening, pale-yellowish, firm, and, as a rule, unaccompanied by areolæ. They were aggregated, or occurred in little clusters of two or three, and

might coalesce. The eruption was usually profuse, and, as a whole, was generally disseminate. In chronic cases there was considerable pigmentation. The itching was intense. Dr. Duhring regarded this variety of the disease as probably identical with the "herpes gestationis" of some authors. The bullous variety showed blebs, having general characters like the vesicular variety, and was liable to be mistaken for pemphigus. The pustular form exhibited itself in variously sized, rounded or flat, usually tense, whitish pustules, resembling impetigo and ecthyma. They inclined to flatten and spread on the periphery, crusting in the center. They possessed, usually, "angry-looking" areolæ, and had a "drawn-up" or "puckered" appearance, and, like the other lesions, tended to be angular in outline. They inclined to form in groups of two or three or more, which might coalesce. The grouping was further peculiar in that the central pustule was often immediately surrounded by a variable number of smaller (pin-point or pin-head sized) pustules, sometimes in a circular form, as in herpes iris. But this arrangement was not constant. This variety of the disease had been described by Hebra under the name of "impetigo herpetiformis."

In all the varieties of dermatitis herpetiformis there was a disposition for the lesions to manifest themselves in patches or in groups, taking on an herpetic character, and to extend about the periphery. A variable amount of constitutional disturbance was present, especially with each new outbreak. The itching and burning were violent. The disease showed a marked tendency to appear in crops, and, moreover, to relapse, its course often extending over years. All regions were liable to invasion. It occurred in both sexes, and usually in early adult or middle life. It was often met with during the parturient state, and was a serious disease, the pustular variety being especially grave. It was very rebellious to treatment. It was a neurotic manifestation. The author had encountered fifteen cases.

He concluded with the following *résumé*: 1. The existence is shown of a distinct, clearly defined, rare, serious, herpetic disease of the skin, manifesting itself usually in successive outbreaks, characterized by more or less systemic disturbance, a variety of primary and secondary lesions, and severe itching and burning. 2. The disease is capable of appearing in many forms, having a tendency to run into one another irregularly, the principal varieties being the erythematous, vesicular, bullous, and pustular, which may occur singly or together in various combinations. 3. The disease is protean in character, and is remarkable for its multiformity. 4. The pustular variety is the same manifestation as that described by Hebra under the name "impetigo herpetiformis." 5. The term "dermatitis herpetiformis" is sufficiently comprehensive and appropriate to include all varieties of the disease. 6. It may occur in both sexes, and in women independent of pregnancy. 7. It usually pursues a chronic, variable course, lasting years, and is very rebellious to treatment.

THE ETIOLOGY OF PERICARDITIS.—Dr. JAMES T. WHITTAKER, of Ohio, read a paper in which he remarked that pericarditis was frequently overlooked, from the fact that its local signs were not generally marked. It often occurred independently of rheumatism, although that was its most important single cause. It occurred most commonly between the ages of twenty and thirty, but it took place in children, and had even been noted in the fetuses. It was most common among those who worked hard. He divided it into two varieties, the consecutive or mechanical, and the infectious or mycotic. The first followed some direct injury from without or within. The second followed the infectious diseases. Any disease produced by a micro-organism might be accompanied with pleurisy. These organisms were especially prone to attack the serous membranes, because, in the

first place, their circulation was sluggish and at times stagnant, and, in the second place, in consequence of the abundance of their lymph spaces. In rheumatism, pericarditis occurred most frequently from the fourth to the fourteenth day of the disease. Tuberculosis might produce this disease mechanically or by the action of the micro-organisms.

Dr. BURRELL, of Florida, referred to the fact that impurities in the blood often caused symptoms closely simulating pericarditis. He also called attention to the frequent mistakes made in diagnosis.

THE PRODUCTION OF POISONS BY MICRO-ORGANISMS.—Dr. BLACK, of Illinois, read a paper which, after an extended review of the subject, he summed up in the following conclusions: "1. All cognizable forms of life are dependent upon the products of molecular change in matter for their continued existence. 2. Every cognizable form of life, capable of independent existence, must have the power of digestion for the preparation of food material for the nutrition of its material structure. 3. Each living cell must appropriate to its nutrition food material prepared by a digestive body of its own or by the appropriation of material prepared for it vicariously by some allied living cell. 4. Every living cell must support its life and material structure by a continued inhibition and remolecularization of matter within itself, except during special provisions of rest, as in the seed, egg, etc. 5. Every living cell must, as a result of the remolecularization of matter within itself, throw off waste products of two classes—a respiratory waste, rich in oxygen, and a urinary waste, poor in oxygen. All waste products are poisonous to the organism from which they emanate. 6. The natural organic poisons are uniformly waste products of the organisms in which they are formed. 7. Pathogenic micro-organisms, by their remolecularization of matter, form poisons analogous to the vegetable alkaloids, which are the active agents in the production of disease. 8. While I should not class the digestive ferments, diastase, etc., as organic poisons, they may act as irritants when applied to another form of life than that which produced them. 9. Normal tissues resist the invasion of the micro-organisms by throwing out matter calculated to destroy them or dissipate or nullify their action, aroused thereto by the presence of an irritant agent given out by the micro-organism."

THE NEW OFFICIAL CHLORATE.—Dr. TRAILL GREEN, of Easton, Pa., read a paper on the chlorate of sodium, which he regarded as far more efficient than the chlorate of potassium. He had been using it since 1866. It was soluble in one and one tenth parts of water. He then mentioned some of the diseases in which he had employed it. It was applicable to all conditions in which the potassium salt had been used. He had employed it in poisoning with the *Rhus toxicodendron* with great satisfaction, bathing the part with a solution of from one to three drachms to the pint of water. For eighteen years he had used no other treatment. A solution of twelve grammes to a litre of water was a soothing application in erysipelas. The caution was given not to allow the cloths saturated with the solution to become dry, because they were readily set on fire. In conjunctivitis a solution of 4 grammes to 500 c. c. of water was of service. The sodium salts did not act on the heart like the potassium compounds. A section of heart-muscle placed in a solution of potassium salt was soon completely paralyzed, but, if removed and placed in a sodium solution, its irritability was regained.

Dr. CALDWELL, of Baltimore, had also used the sodium chlorate with satisfaction, and fully indorsed the statements of Dr. Green.

Session of May 7, 1884.

EPILEPSY.—Dr. WILLIAM PEPPER, of Philadelphia, read a paper on this subject. In a purely clinical discussion of epi-

lepsy, our conception of the disease must be a broad one. Strictly, cases of organic disease should be excluded. This, however, was sometimes difficult. There was no trouble in those instances in which the common symptoms of brain tumor were present, but in those cases in which epilepsy followed sunstroke the distinction was not so clear. Hysteria should also be excluded. While typical epilepsy and typical hysteria were readily distinguished, yet there were many facts showing their analogy. Both epilepsy and hysteria represented conditions of malnutrition with morbid sensibility and irritability of nerve tissue brought about in the most varied manner. In hysteria it would seem that the ganglionic nervous tissue was especially vulnerable, and the gray matter within the encephalon less so, though instability of this might co-exist. Epilepsy would seem to depend upon a supremely unstable condition of one or more areas of the gray matter, rendering it liable to sudden and violent discharges. The most prominent causes were heredity, nervous exhaustion, as from over-growth, over-strain, or exhausting illnesses; shock or sudden powerful impressions, as from physical injury, with or without distinct lesion of the cranial bones; sunstroke; purely psychical shocks, as from fright, instability of the circulation, with disturbed nutrition of the brain, as in heart disease, and, in connection with heart disease, there was a possibility of minute embolisms interfering with the nutrition of small areas; prolonged peripheral irritation, especially chronic catarrhal irritation of the gastro-intestinal tract. A consideration of these points taught that epileptics were not afflicted with a single definite disease, but exhibited in common merely a state of impaired nutrition and morbid instability of the gray matter, varying greatly in different cases. In some cases there were probably minute molecular changes in the nervous tissue. In a larger number of cases, however, the recurring convulsions were connected, not with irregular advancing morbid tendency, or irregularly progressive anatomical change, but with an occasional and irregular operation of those widely different causes which were calculated to disturb the weak center and induce explosive discharges. It was important to recognize the degree of instability. Every one was liable to convulsions; it was merely a question of the provoking cause required. Provoking causes could not be found in all cases of epilepsy, but, the more closely they were sought for, the more frequently would they be found. Scarlatina was frequently followed by epilepsy. In some cases this was explained by the tendency to widespread tissue change, so that impaired nutrition of the gray matter might be expected to occur at times; in other cases this disease might act by leaving such a degree of renal insufficiency as would, under comparatively slight causes, lead to toxæmia, from the retention of malassimilated material, even without albumin in the urine. Where the morbid state had been brought about by sunstroke or exposure to excessive heat, it would often be found that attacks would be induced by undue exposure to the rays of the sun, or even to intense light. When it was associated with cardiac lesion, he had frequently noticed that muscular exertion or excitement of the circulation directly induced the attacks. In all cases, mental excitement, or too close application, or sexual excess, would favor the seizures. The statement that epileptics were in full health did not accord with his experience. Careful study had usually shown some derangement or impairment of important functions. No one plan of treatment was applicable to all cases, or even to a large majority, but each case required separate study and a special line of treatment. The primary cause should be removed if it could be discovered, and the same was true of the provoking cause. The leading principles of treatment were to relieve anæmia, neurasthenia, and morbid susceptibility by diet, change of occupation, change of residence, and rest. Intestinal irritation should be

removed, special reference being made to an absolute milk diet long continued. Other special forms of diet were required in certain cases. Nitrate of silver was of particular value where gastro-intestinal irritation was prominent. Over-exertion should be avoided in all cases, and especially in cardiac cases. Excitement and over-exertion of mind should also be guarded against. Counter-irritation should be employed, the best effect being obtained from the actual cautery, and this was of special value where definite intra-cranial irritation was suspected, as after insolation. The cautery occasionally exerted a good effect in organic cases. Trephining was valuable where circumscribed lesion of the cranial bones was suspected. The removal of genital irritation was important, but the value of circumcision had probably been over-estimated. It is important to arrest the attacks if possible, for their continuance strengthened the bad habit and rendered subsequent attacks more readily developed. The use of the ligature to arrest the aura, nitrite of amyl, and other expedients, might be tried. Various drugs were to be recommended, such as the bromides, belladonna, and asafoetida, enemata of chloral, iron and other tonics. The great value of the bromides was recognized, but caution was to be given in regard to their frequent failure, their abuse, and their dangers. The danger of drifting into a routine treatment was greater, and its results were more disastrous, in this disease than in any other.

Dr. AUSTIN FLINT, Sr., believed that the manifestations of epilepsy were dependent upon a toxic agent of some kind, produced in the body in some manner. He advanced the following points as favoring such a view: 1. The absence of any generally received pathological doctrine. He assumed as a postulate that epilepsy had no established anatomical characters. It might be associated with different lesions, and, in a certain number of cases, no lesion was discoverable. The rational inference was that these lesions had only an incidental connection, if their connection was not entirely accidental. It might also be asserted that the manifestations occurred without being preceded by any morbid condition which could be supposed to be causative. Epilepsy was essentially a neurosis. 2. There was an analogy between the phenomena of epilepsy and those known to be produced by a toxic agent. The closest analogy existed between epilepsy and uræmic coma and convulsions. An attack of the latter might so closely simulate epilepsy, or the reverse, that a diagnosis could not be made until the urine had been examined. Reasoning on the principle that like effects were referable to like causes, he submitted that the pathology of epilepsy was in some sense similar to that of uræmic coma and convulsions. 3. Certain facts in the clinical history of epilepsy were more readily accounted for on the view of a toxic agent than on any other supposition. Among these were the short duration of the epileptic seizure and the immediate recovery, in many instances, of the ordinary condition of health. In some instances the patient felt better after the attack. These facts were explainable on the view that the paroxysm was due to the accumulation of a toxic agent. 4. It was to be remarked that the local pathology did not exclude the probability that certain local morbid conditions were more or less important, and might be necessary to the development of the attacks. 5. Facts pertaining to therapeutics supported the doctrine of a toxic causation. Up to this time pathological views had failed to give a successful direction to therapeutical observations. The action of the remedies which had been found useful, as the bromides and belladonna, might be explained by saying that they enabled the nervous system to tolerate, to a greater or lesser extent, the toxic agent on which the disease depended.

The paper was further discussed by Dr. EUGENE GRISSON, of

North Carolina; Dr. J. F. HIBBARD, of Indiana; Dr. J. J. CALDWELL, of Maryland; Dr. JAMES TYSON, of Pennsylvania; Dr. BARTLETT, of New York, and Dr. PATTEE, of Massachusetts.

THE DIAGNOSIS OF TUMORS OF THE ANTERIOR MEDIASTINUM.

—Dr. JAMES C. WILSON, of Philadelphia, read a paper on this subject. The most frequent tumors were lymphoma, sarcoma, and carcinoma. Carcinoma probably never occurred as a primary disease. Primary sarcoma also was rare. Lymphadenoma was more frequent. The diagnosis of tumors of this space could not as a rule be positively made. The principal symptoms were: pain of a pleuritic character, superficial, not so deep as the pain of aneurysm; dyspnea; dysphagia; constriction and compression in the sternal region. The pain was apt to be paroxysmal, and this had a diagnostic value. Fever was absent unless due to inflammatory complication. Nutrition was often good, emaciation being, as a rule, due to pressure on the œsophagus. Inspection would disclose distension of the veins of the neck, protrusion of the eyeballs, inequality of the pupils, and tumefaction of the face and neck from serous infiltration. Asymmetrical protrusion of the upper part of the chest might also be present. Enlargement of the thyroid gland and of the glands at the root of the neck and in the axilla often occurred. On percussion, a modification of the area of dullness was found. The auscultatory signs varied greatly in different cases. The heart was usually enfeebled and its rhythm disturbed. The respiratory murmur was diminished, and stridor was less common than in aneurysm. Great enfeeblement of the respiratory murmur of one side might be of diagnostic value. The differential diagnosis from aneurysm was to be based on the history, the presence of malignant growths elsewhere, dullness on percussion without the characteristic signs of aneurysm, pain of a stitch-like character, the sense of constriction, and the age of the patient. Tumors were distinguished from pericardial effusion by the irregular outline of the dullness, the greater transverse diameter, the dullness being, as a rule, at a higher level than in effusion, and the absence of any of the common causes of pericarditis. The reader then went on to give the differential diagnosis between the different forms of tumor.

THE PATHOLOGY OF MYOCARDITIS.—Dr. WILLIAM H. WELCH, of New York, read a paper with this title. He thought too little attention was paid to this affection. Diseases of the heart-walls were among the most important to which the organ was liable, and, of all of them, myocarditis was the chief. He then described the anatomical peculiarities of this disease. It was not really an inflammatory change, but the result of degeneration, atrophy, and the deposit of fibrous matter due to defective nutrition. This was brought about by partial occlusion of the coronary arteries, another condition to which too little attention was paid. He reported a number of cases in which examination of the heart during life had revealed no positive signs of disease, but where there were found, after sudden death, occlusion of the coronary arteries and myocarditis. He classed the cases which he had seen as follows: 1. Cases where no symptoms referable to the heart were noticed during life, death occurring from other causes. 2. Sudden death without known symptoms referable to the heart, and where lesions of the coronary arteries and myocardium were the only assignable causes. 3. Sudden death, preceded by one or more attacks of angina pectoris. 4. Cases where some symptoms of cardiac insufficiency had been present for a short time. 5. Cases attended for months with the usual symptoms of disease of the valves of the heart.

The paper was discussed by Dr. FLINT, Sr., Dr. McSHERRY, Dr. DONALDSON, and Dr. JANEWAY.

IRREGULAR APOPLECTIC ATTACKS FROM OTHER CAUSES THAN HÆMORRHAGE OR EMBOLISM.—Dr. GASPAR GRISWOLD, of New York, read a paper in which he used the term apoplexy to de-

note the sudden onset of a train of symptoms in which unconsciousness, hemiplegia, and convulsions were more or less prominent, without any reference to the cause of the symptoms. Pathology taught us the dependence of apoplexy upon cerebral hemorrhage, embolism, and thrombosis, and enabled us to distinguish between them with considerable accuracy. We knew that unconsciousness was most profound in cerebral hemorrhage; that consciousness might be preserved in embolism, even when hemiplegia was well marked, and that in meningeal hemorrhage there might be coma and convulsions with ill-defined hemiplegia. Post-mortem examinations had placed the study of organic brain disease upon a very satisfactory basis. Post-mortem examinations could not help us much in the study of functional disturbances of the cerebral circulation, for it was generally impossible at autopsies to decide whether the brain had been anæmic or hyperæmic just before death. Moreover, cases of functional disturbance of the cerebral circulation, even when sufficiently severe to cause most alarming symptoms, rarely terminated fatally. We were obliged, therefore, to depend upon experiments and clinical observations for what we knew about variations in the intra-cranial blood supply. We found that anæmia of the brain caused coma and convulsions, and that heart failure or vaso-motor nerve disturbance might cause anæmia of the brain. Hence we saw all varieties of symptoms attending functional circulatory disturbances, varying in degree from the lightest shades of vertigo to the profoundest coma. The symptoms of cerebral hemorrhage, embolism, and thrombosis were mainly due to the disturbance of the cerebral circulation which they produced in hemorrhage, by the presence of the clot; in embolism and thrombosis, by occluding the vessels of supply. It was not strange, therefore, that very similar symptoms should be present when similar disturbances of circulation were produced by heart failure, or when the vaso-motor nerves caused the vessels of supply to contract. A striking difference was apparent, however, when we contrasted the persistence of symptoms dependent upon organic disease with the rapid disappearance of those produced by mere functional irregularities. Cases were occasionally met with where coma, convulsions, or hemiplegia, due to mere functional disturbance, for some hours so closely resembled the same conditions dependent on organic disease that the deception was almost beyond detection. In the early stages a mistake was almost unavoidable, and the recovery of the patient was the first thing generally which pointed the way to a correct diagnosis.

The subject was further discussed in connection with the histories of four cases, in all of which an erroneous diagnosis had been made at first, either by the author or by some physician called in at the time of the attack. In all these cases a distinct apoplectic attack occurred, and yet, in all, the rapid recovery from alarming symptoms almost absolutely precluded the possibility of organic disease.

OCULT CAUSES OF DISEASE.—A paper by Dr. W. L. SCHENCK, of Osage City, Kansas, was read by title and referred to the publication committee.

(To be concluded.)

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of May 1, 1884.

Dr. R. A. CLEEMANN, President, in the chair.

CYSTIC LEO-MYOMA OF THE UTERUS.—Dr. HENRY BEATES, Jr., read a report of a case in which the fluid contained the Drysdale corpuscle and other characteristics of typical ovarian cystoma. The early history of this case, owing to the inability

of the patient to state with precision a few minor details, was somewhat incomplete, yet sufficiently accurate to supply a clear, unequivocal clinical record and distinctly demonstrate that the Drysdale corpuscles, when found in considerable number in fluid derived from the abdominal cavity, were not pathognomonic of cystoma ovarii.

Mrs. L., aged fifty-one, housewife, a mother, noticed, four years prior to admission to the Philadelphia Lying-in Charity Hospital, a lump in the lower abdominal region. The menopause had not yet occurred. The tumor was round and painless, and occasioned no inconvenience. Its development was comparatively slow, and not until it had attained large dimensions did it occasion constitutional derangement. When admitted, the patient was markedly asthenic, and suffered from mechanical dyspnea, gastric irritability, subacute proctitis, and pyrexia, the temperature ranging from 99° to 100.5° F.

The facies ovariana and the peculiar atrophy of the soft tissues of the supra-thoracic region, so constant an attendant upon ovarian cystoma, were present in a conspicuous degree. The notes of measurement had, unfortunately, been lost, but an estimate of the size could be formed when it is remarked that the tumor completely occupied the abdominal cavity, everting the xiphoid cartilage and inferior ribs, bulging far over the lumbar regions, and extending over the pubes down and between the thighs. The circumference at its largest portion was about fifty-one inches. The superficial abdominal veins were conspicuous, and the cellular tissue from the mammary zone to the feet was very cedematous. Palpation and percussion revealed signs of an ovarian cyst. The fluctuation was more perceptible in the longitudinal than in the transverse diameter. In the subhepatic region a decided resistance to pressure was noticeable, dependent upon a thickening of the cyst-wall. This mass was attached to the liver at the outer two thirds of the inferior border. At the inner third there intervened a space which was tympanitic on percussion, the note being that of colic resonance. The urine afforded negative evidence. As the asthenia was so profound, it was deemed advisable to tap the cyst in order to obtain an opportunity of improving the general strength and rendering ovariectomy bearable. Dr. Albert H. Smith, who had charge of the case, tapped, employing the ordinary curved trocar and cannula used in tapping the urinary bladder *per rectum*, and withdrew twenty-seven pints of a dark, muddy-brown, grumous fluid of a neutral reaction, a sp. gr. of 1.018, and containing blood and paralbumin. Microscopically, Dr. Beates found red-blood corpuscles, leucocytes, endothelium in various degrees of retrograde metamorphosis—i. e., the corpuscles of Bennett, Nunn, and Gluge—the ovarian cell of Drysdale, cholesterolin, and amorphous detritus. The fluid did not coagulate spontaneously. These micro-chemical properties, coupled with the physical signs, determined a diagnosis of ovarian cyst. The grumous character of the fluid and the existence of the subhepatic mass pointed to a cyst in which carcinoma had become established, with either metastasis to the liver co-existent carcinoma hepatitis. The idea of ovariectomy was abandoned and anæsthesia was instituted, with the effect of improving the patient's general condition sufficiently to enable her to be removed to her home, where she remained under the care of Dr. L. Brewer Hall. In about five months the tumor had refilled, and during Dr. Beates's absence Professor James B. Walker, at Dr. Hall's request, tapped the second time. The fluid was clear, and presented the appearance of ovarian fluid. In the winter of 1882 Dr. Beates tapped a third time, employing an aspirator. The gentleman assisting him inadvertently applied the exit nozzle of the air-pump to the vacuum-jar, and, when the trocar was introduced, there occurred an inflation of the cyst. The air apparently inflated a series of variously sized cysts that were arranged circumferentially and emitted percussion notes of different pitch. From this circumstance, which occasioned no evil consequences, it was concluded that there existed a number of small cysts communicating with the principal one. As the evacuation of the fluid progressed, the umbilical region sunk in, disclosing a circumferential mass presenting the appearance of a wreath, as it were, underlying the abdominal parietes. This ridge could be firmly grasped and moved to a limited extent. This peculiarity determined him to examine the fluid carefully. He also had Dr. Formad examine it, and he pronounced it ovarian. The class

at the University of Pennsylvania was supplied, and the ovarian cell of Drysdale demonstrated. The cyst refilled more rapidly, and he tapped a fourth time, removing a large bucketful of clear fluid, containing the same corpuscles in greater number than the previous specimens; large flakes of coagulated lymph were also evacuated. The circumferential mass had undergone great development, as had also the subhepatic induration. The reaccumulation of fluid was more rapid and the deterioration of health steadily progressing. Death took place about six years after the first manifestations. During the last days of the patient's life Professor Walker, in the absence of Dr. Hall, was in attendance. His letter details the mode of death and the results of the autopsy:

"Mrs. L. died on the Sunday night after your departure. Her bowel trouble rapidly disappeared, but the symptoms of cerebral anemia deepened, with hallucinations and convulsions, until death. At the autopsy the tumor was found to have membranous walls over an area of nine square inches above the navel in the middle line; elsewhere the cyst-wall was thick, as per sample. In some localities, notably in the hypochondria, the wall was quite thick. Firm attachments existed over the anterior wall of the sac with the parietal peritoneum, and the intestines were carried far up under the liver and stomach and were attached to the tumor. The liver was also attached. The entire abdominal cavity was occupied with the tumor, and it dipped into and occupied the pelvis. No attachments existed at the sides nor behind. The uterus was forced downward. One ovary, the right, was normal and attached loosely to the pelvic brim. The other was presumably occupied by the tumor. The cavity of the tumor was occupied by a brownish gelatinous fluid resembling soft soap; it was transparent, but had a sediment consisting of detritus from the inner wall of the sac. There was but one cyst, and the entire interior was similar in its lining, being apparently undergoing erosion. The contents of the cyst measured over a 'Yankee bucketful.' As the tumor was too immense to even contemplate removal, and as the variably thick wall was everywhere similar, save in the pelvic portion, which was darkened from hypostatic congestion, I removed the uterus and the portion of the tumor immediately surrounding it, extending the section through the cyst-wall." [This specimen was presented to the society.]

Sections for microscopic study were prepared from different portions of the cyst-wall, and were all demonstrative of leiomyoma. Those from the subhepatic portion resembled spindle-celled sarcoma, but were clearly differentiated by the elongated nuclei and want of sarcomatous relationship of cells to capillaries. The identity of the clinical phenomena of this neoplasm with those of ovarian cyst was worthy of special attention. In the early stage a marked peculiarity consisted of the sub-hepatic enlargement and induration; a morbid resistance to pressure, noticed in the inferior lumbar regions after the first tapping, and attributed to the œdema, was now seen to have depended upon a thickening wall, which at that time was insufficiently developed, save in the hepatic region, to attract special attention. That all doubt regarding the nature of this neoplasm might be removed, attention was directed to the left ovary, which had undergone marked atrophy and was to be seen in the specimen. Some sections had been submitted to Dr. Formad, who pronounced them ovarian. The origin of the cyst from the fundus uteri was evident upon examination. With the facts before us, Dr. Beates thought it was conclusively proved that the ovarian corpuscle of Drysdale, while a valuable aid to diagnosis, certainly did not possess pathognomonic value.

Dr. DRYSDALE regretted that Dr. Beates had not sent him a specimen of the fluid removed from this tumor, especially as he had more than one opportunity of doing so. While having the highest regard for the opinion of the gentlemen who examined it, still, so many errors had been made in these investigations that it would have been a satisfaction to him to examine it himself. But, apart from this regret, he considered it by no means proved that the cyst in question was not ovarian. The portion

of tumor left attached to the uterine wall in the specimen resembled a closely adherent ovarian cyst, such as he had met with repeatedly. The little mass lying close to the uterus, described as an atrophied ovary, did not present any resemblance to an ovary, nor did it occupy the usual position of that body. In the description no reference had been made to the color of the tumor, which had an important diagnostic value, the uterine fibro-cyst being usually livid or purplish in color, while the ovarian had a white, pearly hue. It was especially in cases like that of fibro-cyst of the uterus where the importance of the ovarian cell in diagnosis was well marked. In his investigations of these tumors he had never met with the cell which he had described as ovarian. Mistakes were very easily made in the differential diagnosis of such tumors, and, in fact, in many cases the diagnosis could not be established except by the examination of the fluid or by opening the abdomen. For want of this examination of the fluid, he had seen Sir Spencer Wells make the abdominal section to remove a tumor which he had diagnosed as ovarian, but which proved to be uterine. Dr. Marion Sims had sent him on three different occasions, and without telling him that they were from the same patient, specimens of fluid, which he thought was ovarian, obtained from a cyst in the abdomen. Dr. Drysdale assured him that the fluid was not ovarian, but, after the examination of the last specimen, Dr. Sims, still doubting, determined to operate, and found a uterine fibro-cyst. The history and all the characteristics of the tumor described this evening were ovarian, and the specimen and autopsy were not sufficient to establish the diagnosis of uterine cyst.

Dr. B. F. BAER remarked that the specimen seemed to be a section of a fibroma arising from the uterus, but it was too small to be satisfactory or to prove its origin. His personal experience had taught him the diagnostic value of the Drysdale corpuscle. When Dr. Formad reported finding this cell in the fluid removed from an abdominal tumor, he felt strengthened in his diagnosis of ovarian cyst. He had not trusted to the cell alone, but had been greatly influenced by its presence or absence in making a diagnosis in doubtful cases. In every instance in which Dr. Formad had reported finding the ovarian cell, operation had proved the tumor to have been of ovarian origin. He would like to ask Dr. Drysdale if he still considered the cell pathognomonic.

Dr. DRYSDALE still believed in the pathognomonic value of the ovarian cell. In his investigations he had met with but one exception to the rule, and that was in renal cysts. To prove that the cell could be relied on to establish a diagnosis, he would give one or two instances where it was impossible to do this except by its aid. In a review, by Dr. Harris, of the "Transactions of the American Gynaecological Society," in the "American Journal of the Medical Sciences," would be found this statement: "On one occasion Professor D. Hayes Agnew gave Dr. Drysdale a fluid for examination, in which he found the characteristic cell. Upon stating to Dr. Agnew what he had found, he was told that the fluid had been taken from the abdominal cavity; upon which he immediately said that the fluid must have escaped from an ovarian cyst, for it was ovarian. In this he was correct, as the cyst had a small hole in it, as if made with a punch, and the fluid had escaped as claimed." In another case Dr. Drysdale received a letter from Professor Matthew D. Mann, of Buffalo, N. Y., with a specimen of fluid consisting of eight or ten drops, which the doctor stated was all that he could obtain by aspiration. The tumor had been diagnosed by other surgeons as a uterine fibroma, and consisted of a large solid mass which filled the pelvis and abdomen as high as the umbilicus. The history and symptoms all pointed to a uterine fibroid, and the patient was in such a precarious condition that an explora-

tory operation was considered unjustifiable. An examination of the fluid by Dr. Drysdale showed the presence of the ovarian cell. This determined Dr. Mann to operate. He found two ovarian tumors, which he removed successfully, and the patient recovered. "Without the microscope no certain diagnosis could have been made except by resorting to an exploratory incision." These cases, and he could give many others like them, were sufficient to show the diagnostic value of the cell.

Dr. BEATES remarked that it was a matter of extreme regret to him that Dr. Drysdale did not have an opportunity of examining the fluid; it was due to the fact that the neoplasm was regarded as ovarian, and the specimens of fluid were not preserved. At the autopsy the growth was presumed to have arisen from the left ovary, and none of the fluid was kept. Later study of the specimen disclosed the amygdaloid mass situated in an atrophied membranous structure, closely approximated to the uterus. The microscopic examination of this determined its ovarian character to the mind of Dr. Formad, which conclusion dissipated a doubt in Dr. Beates's mind and confirmed his belief of its being the left ovary. He thoroughly appreciated the strong probability of error in positively diagnosing by differentiation the Drysdale corpuscle from similar bodies, as the pyoid body of Lebert, but the facts that treatment with acetic acid only had the effect of rendering the whole corpuscle very slightly clearer and disclosed no nucleus, that ether added to the fluid, the mixture being thoroughly agitated for several minutes, had the effect of simply rendering the corpuscle paler, convinced him that the bodies were the corpuscles in question. There was, by very extended experience, developed a capacity to differentiate by a varying degree of opacity. Dr. Formad believed these corpuscles to be those of Drysdale. The striking phenomenon, if this were an ovarian cyst, was in the fact that primarily it was purely cystic, typically so, and that during the last year of its existence the cyst-wall throughout its posterior seven eighths assumed a myomatous development. If this did not occur, the myomatous wall must have originated at the fundus uteri and gradually permeated the cyst. Either of these processes was almost incredible and certainly exceptional. The true uterine origin must not be forgotten. That a proper conception of the tumor might be formed, it should be compared to a large pumpkin with a wall varying in thickness from one to three inches. For an area of about nine square inches at the umbilical region the ordinary cyst-like structure formed, as it were, a drumhead. This wall was not fibromatous, but purely myomatous. Dr. Goodell had seen this patient, and diagnosed the tumor as ovarian.

HYPERTROPHIED UTERINE MUCOUS MEMBRANE.—Dr. BAER exhibited a specimen, and related the case.

R. H., aged thirty, married twelve years, was sterile. Puberty occurred at the age of twelve. There was slight dysmenorrhœa from the first, and since her marriage the difficulty had been increasing, so that during the last few years the pain had been very severe. The menstrual flow, which had always been rather profuse, especially since her marriage, had for more than a year been irregular in time and quantity; sometimes it continued two weeks very freely, when she would be so prostrated as to be compelled to remain in bed to regain strength. She complained of a severe, sharp pain in the region of the left ovary, radiating to the groin and the anterior part of the thigh, and to the pericardial region and side of the head to the top of the head. She had great dragging in the pelvis and pain in the sacral region. During her periods the mammary glands would swell and become very tender and sore. Coition had been rendered almost intolerable on account of pain during the act, and because it increased the pain in the left ovarian region and induced a sensation of nausea and faintness. She had such dread of sexual congress that an interval of months would sometimes elapse between the acts. Her weight had decreased from 146 to 117 pounds, and her appetite and digestion were poor.

Examination showed the cervix uteri to be near the vaginal orifice, somewhat elongated and conical. The os was patulous, the body of the uterus very much hypertrophied and retroverted. The left broad ligament was contracted and the corresponding ovary prolapsed, larger than normal, and very tender to pressure. The sound indicated a uterine depth of three inches and a half, and the organ was large and soft. The uterus was mobile. Ether was administered, the cervix was dilated by means of Ellinger's dilator, and the endometrium was carefully curetted, removing a large amount of the most enormously hypertrophied mucous membrane. Nitric acid was applied. Under a regulated diet, with rest, complete relief followed, and freedom from hæmorrhage and pain.

Dr. W. H. PARISH would like to hear the result in Dr. Baer's case after the lapse of three or four years. Two or three years ago he had reported before this society a similar case, in which, after dilatation by sponge-tents, he had removed a large quantity of endometric growths, and applied nitric acid. The treatment was followed by an apparent cure which lasted for some months, after which the previous condition returned. The same treatment, followed by relief and subsequent relapse, had been repeated several times. Good microscopists had pronounced the growths benign. Dr. Goodell had, however, given it as his opinion that it would ultimately become malignant. Dr. Parish had been gradually coming to the same opinion.

Dr. BEATES had treated a woman aged thirty-three years, who suffered from antelexion of the uterus, menorrhagia, and granulations of the endometrium. The microscopic appearance was benign. After treatment by means of the curette and nitric acid, no hæmorrhage occurred for four months, the treatment was repeated, a laceration of the cervix was closed, and seven months later the patient became pregnant; abortion occurred at two and a half months, and the granulations and hæmorrhages had returned.

Dr. BAER remarked that these cases were very common, being seen every week at the clinic. They were usually benign, but sometimes became malignant from loss of blood and a run-down condition of the system. Adhesions or some other obstacle to the free return of the venous blood from the uterus might exist, or the ovaries might be diseased, and these causes would bring on the relapse, no matter how perfect the relief might be. In many cases the cause was a flexion, and the effect was sterility. It was an exaggeration of a purely physiological process. It might be benign in its incipency, but become malignant later on.

W. H. H. GITHENS, M.D., *Secretary.*

Miscellany.

PROPER MEDICAL EDUCATION.—The following is an abstract of a paper read before the Medical Society of the State of Pennsylvania, May 14, 1884, by Henry Leffmann, M.D., of Philadelphia: The present system of medical education is not the result of efforts to meet the needs of the community, but is largely an irregular development. The reforms which medical colleges have adopted have been mostly unwilling concessions to public sentiment. The sevenfold division of branches has nothing to recommend it but antiquity; it is not a convenient nor a scientific division of the subject. Under the arrangement some of the departments of the college course are overcrowded, others have not sufficient matter to occupy the time assigned. Departments like hygiene, mental and nervous diseases, and medical jurisprudence, have developed so of late years that they might properly be taught by separate chairs and not made merely subsidiary to other chairs, or limited to spring or fall lectureships. The extension and success of post-graduate schools

indicate the direction in which the improvement of the curriculum should be made.

Higher specialization is the necessity of the time. The success which has been attained by dentistry shows that other departments, such as otology, laryngology, etc., might with advantage be pursued independently. There would be no reasonable objection to establishing the degrees of doctor of otology, ophthalmology, and so on, commensurate with the degree of doctor of dental surgery.

A preliminary training for the student before entering on the study of medicine is so obviously necessary that it need not be argued.

The final work of medical reform will be accomplished when the college is made merely the instructors the license to practice being given by an official board of examiners after a written public examination.

COFFEE MANIPULATION.—If a large part of the coffee produced was left longer upon the tree it would reach the consuming markets of the world in a riper condition than at present. The result would be coffee with a better or more mellow flavor, larger bean, and of much more desirable color. The berries, however, are picked at or close to maturity; by artificial means the outer coverings, consisting of the skin of the berry, the pulp, mucilaginous surroundings, and the inner skin, are removed. The bean improves by age at the expense of weight, gaining in color and flavor, and therefore in commercial value. Popular prejudice accepts a dark brown or rich golden color as an evidence of age, and hence an index of drinking quality, and, as a result, such coffee commands a higher price.

Producers hurry their coffee to market. In many countries, owing to a lack of machinery, it reaches the shipping port poorly cleaned; in a raw or unripe condition; beans of irregular size and of varying flavor. From shipping ports it is hurried to the distributing ports of consuming countries, generally by steamer, instead of, as formerly, by sailing vessel. The result is that the coffee loses the benefits that resulted from a long sea voyage, viz.: improved color and flavor due to the fermentation or sweating process it undergoes while confined in the hold of a vessel subject to a high and moist temperature. A six months' voyage via Cape of Good Hope imparts to the large green Java bean a dark brown color, and gives to it the mellow flavor so popular with consumers.

Various artificial means are now employed to give to coffee color and flavor, some of which are legitimate and others fraudulent or illegitimate. In that standard authority, "Coffee from Plantation to Cup," attention is called to the report in 1879 of the chemist of the Agricultural Department, Washington, D. C., wherein he states: "The foolish demands of the people are the direct cause for the manipulation of coffee." He proved by chemical analysis that six samples of faced berries contained the following per cent. of foreign adulterants:

	Per cent.		Per cent.
No. 1.....	0.68	No. 4.....	0.64
No. 2.....	0.19	No. 5.....	0.63
No. 3.....	0.08	No. 6.....	0.58

The mixtures used are known as orange powder; black powder; olive green powder. They contain chromate of lead ("chrome yellow"); sulphate of barium ("heavy spar"); burnt bones or crude bone black.

Dr. Cyrus Edson, of the New York Board of Health, has been paying special attention to the fraudulent coloring of coffee, and not only corroborates the foregoing, but has discovered that mineral poisons are freely used by several of the companies operating in Brooklyn, N. Y., and which are to answer for their wrong practices to the Board of Health of that city. Arsenic, Venetian red, chromate of lead, ferrocyanide of potassium, and umber are used to color the beans. The bean, being porous, or spongy, absorbs the arsenic and lead so thoroughly that it is almost impossible to remove it by any roasting or chemical process. If these mineral poisons remained upon the outside of the bean it would require a white heat to destroy them; and every dealer knows that coffee is roasted in closed cylinders at a temperature which fails to volatilize any poisonous coating. It is incomprehensible how any firm of good standing can be a party to such frauds.

The polishing of coffee, by subjecting it to friction in either upright or horizontal cylinders, is legitimate. Neither can any reasonable ob-

jection be made to the use of soap-stone in polishing. The separation of small from large beans, or the improvement of the looks of the coffee by mechanical appliances, are proper, adding to its commercial value, but there is no defense that will excuse the use of mineral poisons.

Any artificial method, whether legitimate or illegitimate, can be used to deceive, and we regret that so many reputable firms are practicing fraud upon retailers by using existing processes of manipulation. Large bean coffee of Mexican, Central American, Venezuelan, or other growth is made to imitate Java so closely as to defy detection except by experts. That sort of swindling has become very common, and we caution the trade against "bargains" in old brown Government Java.

Some years ago a patent was taken out for the ripening of coffee by a natural or legitimate method. This subjects the coffee to the equivalent of a long sea-voyage through the tropics. The coffee is placed in compartments similar to the hold of a vessel, and subjected to a moist and rising temperature for about one week. The rise in temperature is gradual, and the success of manipulation depends upon the skill of the operator, whose experience enables him to determine from the condition of the green bean the degree of heat and moisture to which it can be subjected, and the time necessary to secure a certain result. The operation removes from the bean a large amount of caffeo-tannic acid, causes some varieties of the bean to expand and change color, and becomes mellow in flavor.

The process causes a permanent change, specimens four years old showing no loss of color. The flavor, as is natural, will continue to improve by age, notwithstanding the treatment to which it is subjected. The caffeo-tannic acid of coffee has the property of taking up oxygen and oxidizing rapidly, forming other acids. The color of the bean is supposed to depend more or less upon the changes in these acids. If live steam is allowed to act directly upon raw coffee it would partially cook it, the action being sudden and violent; but this method, once in vogue, is little practiced at present.

It is unimportant to the consumer whether the changes which improve coffee are wrought on sea or land, so long as they are obtained without the use of chemicals or by any methods likely to be injurious to health. The method above described is now extensively used to give to green Java a rich, brown color, and to green Rio and Santos that much desired and beautiful golden color. It is also possible to establish and maintain a uniform standard of color. This process has also afforded additional proof that soil, climate, and condition of bean at the time of harvesting affect the flavor. It serves to lessen the rank and bitter flavor of Brazil sorts and bring some varieties of Santos and fine Rios so that they approximate in mellowness an O. G. Java or fine Maracaibo.

In brief, fermentation under certain conditions improves some sorts of coffee. It undoubtedly improves by age, some claiming that it will gain in flavor for ten years, if kept in a dry, warm, well-ventilated warehouse at as near an even temperature as possible. It loses or absorbs moisture, according to existing climatic conditions.

Buyers should guard against fraud, and, when they are deceived, return the goods or claim an allowance for damages.

We will cheerfully examine and report upon any samples which our subscribers will send, provided they are sufficient in quantity (not less than one pound) and come properly labeled, accompanied by a description by letter.—*American Grocer and Dry Goods Chronicle.*

SARCO-PEPTONES.—This preparation of Dr. Rudisch, presented by the house of Parke, Davis & Co., is offered by them as a thoroughly successful peptonized beef extract. It is in the form of a translucent, firm jelly, of an amber-brown color, and the odor and flavor of a good extract of beef. Dr. Jacobi, of New York, has used it for a long time in preference to any other preparation of the kind, his reasons being "the absolute uniformity and equality of the specimens, and the fact that the patients, as a rule, have been willing to take it for a long period in succession." He gives it unmixed in teaspoonful or half-teaspoonful doses every half hour, hour, or two hours, or diluted with broth, or spread on stale bread or toast, or mixed with water for rectal injections. We have not as yet tried the preparation, but propose doing so upon the first occasion which offers.—*Virginia Med. Monthly.*

Original Communications.

THE CLINICAL SIGNIFICANCE OF FIBRINOUS EXUDATIONS UPON THE MUCOUS MEMBRANE OF THE UPPER AIR-PASSAGES.*

By FRANCKE H. BOSWORTH, M. D.,

PROFESSOR OF DISEASES OF THE THROAT IN BELLEVUE HOSPITAL MEDICAL COLLEGE; PRESIDENT OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION.

By clinical observation, inflammatory affections of the upper air-tract divide themselves, by sharp, well-defined lines, into catarrhal inflammations and those characterized by fibrinous exudations. In the former we have to do with a morbid process, usually of a mild type, of limited extent, and of short duration. In the very large majority of cases it is due to taking cold, which gives rise to a more localized perversion of the ordinary process of nutrition and growth, that exaggeration of the normal physiological processes which goes on in the part in a state of health, and which we call a catarrhal inflammation. The process is in no essential sense a grave one; it is attended with no dangerous tendencies except such as may be adventitious, and the constitutional disturbance, if there be any, is measured by the extent of the local morbid process. In other words, the fever, if it be present, is limited by the extent of inflammatory action, and is merely symptomatic of it. The disease itself is purely a local one.

On the other hand, inflammatory processes characterized by the exudation of a fibrinous material in or upon the surface of the mucous membrane indicates a disease totally distinct, and in every aspect differing from a catarrhal process. In the latter the phenomena differ in no essential manner from health except in the exaggerated activity. There is increased blood supply, there is increased cell proliferation, there is increased secretion. These processes all belong to the membrane in health, and hence inflammation here only consists in an intense activity of all the normal physiological processes. In the inflammatory processes, on the other hand, characterized by a fibrinous exudation, the essential features of the morbid process are different. It is generally stated that the two processes are much the same, with the exception that in the one case there is the additional element of a fibrinous exudation. From a clinical standpoint, this is scarcely true. Hyperæmia is common to each, but more marked in the catarrhal process. Hypersecretion is common to each, but much more active in the simpler disease. Cell proliferation is common to each, but, while in a catarrhal inflammation this is characterized by intense activity, in an exudative affection this phenomenon is not a prominent incident. But while in these three features the catarrhal disease is much more active, we have in the exudative process an element added which indicates the existence of, not a mere local process, but a constitutional affection, and one which may be attended with great danger to life.

By far the most common of all inflammatory affections occurring in the upper air tract, attended by a fibrinous exudation, is what is known as *acute follicular tonsillitis*. A child or an adult, for it is common to all ages, after a few hours or, perhaps, a day of general malaise, is seized with a chill followed by high fever. The chill is usually well marked, but may be only decided chilly sensations. Following the chill, well-marked febrile symptoms set in, characterized by hot skin, rapid pulse, thirst, pain in the bones, anorexia, and all the symptoms of active fever, the temperature often rising to 103° or 104°. Painful symptoms with reference to the fauces soon set in, with marked dysphagia. An examination of the throat reveals one or both tonsils swollen, hyperæmic, and dotted over with a number of pearly white patches. The essential morbid condition here consists in an exudation, into the crypts of the follicles which go to make up the tonsils, of a fibrinous material which distends their cavities and shows itself at their orifices. An examination of the material poured out shows it to be in the main composed of delicate fibrinous fibrillæ, inclosing in their meshes a number of lymphoid corpuscles. As the disease progresses, the fever diminishes in activity, the morbid process in the tonsils gradually disappears, and, at the end of from five to eight days, it terminates in resolution. The prominent features of the attack are the marked febrile motion which characterizes the onset of the disease and the marked constitutional disturbance which attends its course, the prostration often assuming a typhoid aspect.

We have here, then, a limited and comparatively trivial morbid process in the fauces attended with such marked systemic disturbance that I think it must be conceded that we have to deal with something more than the results of an ordinary cold. The whole train of symptoms is such that it seems to me that we may rather regard it as akin to the essential fevers, the fever and general systemic disturbance being such that we can not regard them as symptomatic of the limited inflammatory process in the tonsils. A clearer and more intelligent appreciation of the affection can be attained, then, by regarding it as not differing in any great degree from the exanthemata, but by considering it one of the continued fevers with a local eruption on the tonsils, the characteristic appearances of the eruption being as distinctive and pathognomonic as the umbilicated pustule is of variola.

If this conclusion be a justifiable one, we must seek further for its cause than in taking cold. I believe it to be a germ disease. A floating germ, whose origin is in many cases to be found in defective drain-pipes, bad sewage, or some of the many problematic sources of our zymotic diseases, lodges upon the tonsils, and, finding a favorable nidus for its development, makes its way into the blood, causing the general systemic outbreak which characterizes the affection, while at the same time a local morbid process is set up at the point of inoculation. It may be claimed that many of these cases seem to develop from a recognized exposure to cold, just as many cases of croupous laryngitis are preceded by a catarrhal laryngitis. The true explanation of this is that a catarrhal inflammation in the fauces

* Read before the American Laryngological Association, May 12, 1884.

favors the lodgment of the germ; in other words, predisposes to the attack.

Another group of cases which is characterized by a fibrinous exudation is the so-called *acute follicular pharyngitis*. In these cases the train of symptoms is identical with those already described. The only difference is that the follicles of the lower pharynx are involved in place of those of the tonsil. In these cases, the same conclusion may be drawn as from the tonsillar disease, the only difference being in the locality of the eruption.

Another group of cases is met with in which the same morbid process occurs in the follicles of the pharyngeal tonsil, constituting an acute follicular tonsillitis, if we may so call it, of Luschka's tonsil. Anatomically, physiologically, and pathologically, I know no difference between the faucial and pharyngeal tonsil. Their general construction is identical; the function of both is to supply mucus as a lubricant to the lower pharynx, which is but sparsely supplied with mucous glands, and their diseases are also the same. Quinsy, or so-called acute tonsillitis, is the only exception, but this is not a disease of the tonsil, but rather of the areolar tissue of the soft palate.

Acute follicular tonsillitis of Luschka's tonsil has never, as far as I know, been described, and yet it is of very common occurrence. It differs in no essential degree from the disease first alluded to, its onset and progress being marked by the same active systemic disturbance, and its clinical significance being also the same as that of the former disease.

Still another class of cases, which forms a group by itself, is croupous tonsillitis. In these cases a child or an adult—far more frequently the former—is seized with a chill followed by general febrile movement and pain referable to the fauces. The febrile movement is, as a rule, of a notably active character, the pulse being rapid, the skin hot and dry, thirst and anorexia well marked, and the temperature reaching 102° to 104° . An examination shows one or both tonsils swollen, hyperemic, and the seat of a small patch of a fibrinous exudation of a grayish white or bluish white color. A close and careful examination of the patch shows it to be a clean, clear, white membrane, with no noticeable secretion. Now, if we take a slender probe, and very gently lift the edge of the membrane, and we find that it is easily removed, and, moreover, that after removal the mucous membrane beneath presents a fairly normal appearance—in other words, if we find that the exudation can be peeled off without rupturing any blood-vessels or causing hemorrhage—I think that there can be no question that we have by this procedure obtained most valuable information by which we can form a fairly correct opinion as to the character of the disease with which we have to deal—its courses, dangers, and tendencies. In adults and patients who have passed beyond the age of childhood we may say with certainty that we have to deal with a self-limited disease, and one which will run its course in from five to eight days, and that it involves no dangerous tendencies.

In young children, on the contrary, the development of a fibrinous exudation in the fauces means the possibility of the occurrence of one of the gravest diseases with which we have to deal—croupous laryngitis. A child is attacked

primarily with a train of general symptoms, as noted before—a chill, and general febrile motion of an unquestionably sthenic type, followed by a fibrinous deposit on one or both tonsils. The case progresses without any untoward symptoms for two or three days, when laryngeal symptoms develop, and a fibrinous exudation of the same character develops in the larynx. In these cases, as in the acute follicular diseases first described, I think we have to do with a specific germ which lodges upon the mucous membrane of the fauces, where it reproduces itself, setting up local inflammatory action, while at the same time it makes its way into the circulation, thus producing the systemic condition which characterizes these affections—viz., sthenic fever. In childhood the germ finds a favorable nidus for its development upon the tonsils, and also upon the mucous membrane of the larynx. In many cases the germ which excites the laryngeal complication probably has its origin in the reproduction which occurs at the point of primary inoculation—viz., the tonsillar false membrane. With increasing years, the changes which take place in the laryngeal membrane render it a less favorable nidus for the development of the germ, and so in adult life we have the croupous deposits upon the fauces, without involving any additional danger of a laryngeal complication. In itself, a croupous membrane is not dangerous. Occurring on the tonsil of an adult, it involves a week of moderate illness. In children, and occurring in the larynx, it constitutes one of the gravest of diseases, but mainly in the mechanical obstruction to respiration. I should say here that the term croupous membrane is used, as originally laid down by Virchow, to describe a fibrinous exudation deposited on the surface of a mucous membrane, in contradistinction from a diphtheritic membrane, which infiltrates the mucous membrane to a greater or less extent, and can not be separated from it.

In another group of cases we have the well-marked preliminary chill followed by general febrile disturbance, with faucial exudation; but the characteristics of the local morbid process, as well as the systemic symptoms, are entirely different. The febrile motion is of a different type, being of a notably asthenic character; the pulse is rapid but weak; the temperature is lower, being 101° to 102° . The skin does not usually present the hot, flushed aspect of the sthenic fever, and there is every appearance of marked depression. If we examine the fauces on the first day, we find deposited upon one or both tonsils a thick, velvety, distinctly yellow false membrane, markedly raised above the surface of a moist-looking membrane, and a notable amount of secretion about its border. If we take a probe and try to raise its edge, we find it impossible to do so without lacerating the tissues. On the second day we find that a decided change has taken place in the membrane. The local necrosis has taken place, which is the necessary result of the fibrinous exudation having permeated the mucous membrane; and the whole appearance is of a slough, a blackish-yellow mass, with an offensive discharge oozing from its borders and giving forth a fœtid odor. Here also the local morbid process may be confined to the fauces, or in a few days laryngeal symptoms may develop, and a false membrane

form in the larynx. Unlike the croupous form of fibrinous deposits, the tendency to the occurrence of laryngeal complication is not confined to children.

Diphtheria, in all its aspects, is a septic and asthenic disease, and presents a totally distinct clinical picture from croup; and yet, it seems to me, there can be but little doubt but they are both germ diseases. In diphtheria, the germ lodges upon the mucous membrane of the fauces, and, exciting a local inflammatory process at its point of entrance, makes its way into the blood, producing there the train of symptoms which constitute the essential constitutional features of the disease—viz., primary septic blood-poisoning. At the point of inoculation the germ reproduces itself, and constitutes the source of a secondary blood-poisoning by absorption from the false membrane in the fauces.

In addition to the sharply defined groups of cases which I have briefly described, we all of us occasionally meet with cases; which it is impossible to assign to the croupous or diphtheritic group. Fortunately, these irregular and indefinite cases are rare. In the very large majority of cases, however, I think that we may assign a given case to one of the groups described with tolerable certainty as to the correctness of our observation.

It is not the province of this paper to discuss the question of the identity of croup and diphtheria. In 1857 Virchow enunciated the doctrine that, from a pathological point of view, there were two distinct pathological processes to be found in connection with false membranes in the air-tract. In the one case a fibrinous exudation was deposited on the surface of the mucous membrane, and that this constituted a croupous inflammation; on the other hand, a fibrinous exudation which permeated the mucous membrane constituted a diphtheritic inflammation. As is well known, Virchow subsequently abandoned this distinction, on the ground that the two pathological processes in many cases merged so gradually one into the other that it was impossible to assign them to either class with certainty. No one, of course, doubts the correctness of Virchow's later views, and yet, from a clinical standpoint, I regard the distinction as one of the very greatest importance. And while, as already stated, we undoubtedly meet with cases which it is difficult to assign with certainty to either class, these cases are rare, and, in the very large majority of cases, the differential diagnosis is not difficult if we carefully examine the local process.

The points, then, on which I would place especial emphasis are as follows:

1. A fibrinous exudation which occurs in the crypts of the follicles of the faucal or pharyngeal tonsil, or of the mucous membrane of the lower pharynx, has no tendency to extend, and characterizes a disease which is self-limited and which involves no dangerous tendencies.

2. A fibrinous exudation which occurs upon the surface of the tonsil or of the mucous membrane of the fauces, constituting a croupous membrane, so called, presents gross appearances by which it can be unmistakably recognized. It is easily detected, and can be peeled off from the parts beneath without lacerating the tissues. It is a white, clean,

healthy-looking membrane, and presents every aspect of a living tissue.

3. A croupous membrane in the fauces of an adult marks the existence of a disease which, while being undoubtedly a blood-poison, is still a self-limited affection, and one which involves no danger to life.

4. A croupous membrane forming in the fauces of a child marks the occurrence of the same disease as a croupous membrane in an adult; but in the child there is the additional danger of a new center of development occurring in the larynx, where it may involve the greatest danger to life, but mainly as a mechanical obstruction to breathing.

5. A diphtheritic membrane developing in the fauces marks the occurrence of a disease which is dangerous to life, not only from primary and secondary blood-poisoning, but also from the tendency to the development of the same morbid process in the larynx.

DISCUSSION.

Dr. BEVERLEY ROBINSON, of New York.—I would take exception, with due respect to the author of the paper, to certain statements which he has made. In the first place, with regard to the question of follicular tonsillitis, so-called, appearing as an essential fever, I think, from a clinical point of view, that this is a mistake, because, while it is certainly true that in a certain number of instances, particularly in children, the fever does last for a number of days, and is evidently connected with the appearance of cheesy masses over the follicles of the tonsils, yet in quite as many instances the fever is of very short duration, and, although it may be ushered in with phenomena of some gravity, in such cases I have seen it subside within from twenty-four to forty-eight hours. Moreover, as far as I am aware, and I say this with a little hesitancy, the pathological appearances of the exudation from the interior of the follicles does not resemble, microscopically, the condition to which the President alluded in speaking of the true croupous membrane. They are simply cheesy masses which are pressed out from the interior of the crypts, and do not in any sense partake of the nature of an exudation which we consider ordinarily as being fibrinous.

With regard to the question of croupous tonsillitis, I will also remark that, while there are perhaps many cases in which the membrane itself does characterize the type of a disease which is only of certain local gravity, particularly when it attacks the larynx, but which is not a constitutional affection, yet I have seen cases in which the mucous membrane did not seem to be incorporated with the false membrane itself, where the cases seemed to be of mild type, yet after a few days they became very serious; the membrane, which at first was white and easily detached, afterward became dark, and so attached to the underlying tissues that I could not say the case was not one of diphtheria. I think there is a certain number of cases ordinarily called croupous tonsillitis which in all probability begin, as stated by several authors, among them Dr. Da Costa, in a herpetic eruption of the tonsils. I think that such a disease unquestionably exists. I have seen one or two cases almost from their commencement, and think the disease should be considered a follicular tonsillitis, or a herpetic tonsillitis rather, a form of tonsillitis alluded to in the first part of the President's paper. I might here say, as to the origin of these affections in the local absorption of certain germs, that while the President's views, shared by many others, may have a theoretical basis, they are in my mind far from proven. We unquestionably do find in these affections of the air-passages germs—call them bacteria

or what you will—but the microscope will fail to show the slightest difference in their appearance, whether they be present in one affection or another, and we are unable to say whether the germs were active in carrying the poison or whether they were entirely innocuous.

It is very wrong, in my opinion, to look upon diphtheria as always being one and the same disease in the sense of its absolute gravity. There are different gradations in the gravity of diphtheria, as in all infectious disorders. As we meet with cases of scarlet fever and measles of mild type, so also of diphtheria, and the prognosis must vary according to the circumstances of the case, and yet the disease is essentially the same in each case.

Dr. WILLIAM C. JARVIS, of New York.—I can, for the most part, substantiate the views of Dr. Bosworth as regards the gross pathology of the exudation met with in the upper air-passages. Several years ago my attention was first called to inflammation of the pharyngeal tonsil by the occurrence of the affection in my own person. My inference as to the implication of the third tonsil was afterward verified by repeated observations upon numerous subjects of this disease. A feature of acute follicular pharyngitis which does not seem to have received any attention is one in which the secretion is retained, eventually escaping upon rupture of the membrane, and covering the pharynx with a white membrane. Such a change does not occur when the inflamed follicles remain patent.

The PRESIDENT.—I must take exception to Dr. Robinson's belief that follicular tonsillitis, in any sense of the word, is characterized by cheesy deposits in the crypts of the tonsils. The exudation, in its gross appearances and microscopical characters, while not presenting exactly the same conditions which we see in the croupous membrane on the surface, resembles it sufficiently to warrant us in the conclusion that the two conditions are very nearly allied, if not identical, the differences being only such as we would expect to find—the membrane in the one case being deposited upon the surface, and, in the other, being confined to the small crypts going to make up the tonsils. Again, in some cases the membrane overflows the crypts, so to speak, and spreads out on the surface, constituting a membrane in the true sense of the word.

The point which I wish distinctly to emphasize is, that we can, by examination, throw a great deal of light on the clinical tendencies of inflammatory diseases of the fauces. Heretofore, as you know, physicians have commonly limited themselves to making examination, and drawing their conclusions, simply from the use of the tongue depressor. It seems to me, from a clinical point of view, the careful examination of the gross appearances of the exudation in the fauces has not received the attention which it should. If, for instance, in acute follicular tonsillitis we can recognize by the gross appearances a membrane, which will enable us to say in the case of the adult exactly what course the disease is going to follow, or, in the case of the child, that there is danger of a new center of development—the larynx—and of consequent obstruction to the air-passages, we shall take an important step in advance.

As regards the germ source of this disease, it seems to me that, in the absence of any more definite theory, this presents the best explanation of the etiology. It can not be a disease which results from taking cold; it is something more than that. It presents all the general systemic disturbances which characterize the essential fevers which are self-limited in nature.

Dr. F. I. KNIGHT, of Boston.—I would call attention to one point which I think escapes the attention of physicians very generally in these acute affections of the upper air-passages, and I do so because I think it practically important. It relates to the increased susceptibility to diphtheritic infection during the existence of any simple acute inflammation of the air-passages, as

follicular pharyngitis or simple pharyngitis. This fact induces me, and I think it should induce others, to give a guarded prognosis in even simple acute affections.

Dr. S. W. LANGMAID thought there might be the symptoms of only a simple pharyngitis in the beginning, while the case, in fact, began as one of diphtheria, and left no doubt of its nature later.

The PRESIDENT explained that the point made in his paper was that a membrane in a state of acute inflammation afforded a better nidus for the germ which developed the diphtheritic or croupous process than the healthy membrane did.

FÖRSTER'S OPERATION FOR THE RAPID ARTIFICIAL RIPENING OF CATARACT,

WITH AN ANALYSIS OF THIRTY CASES.*

By CHARLES STEDMAN BULL, M.D.,
NEW YORK.

In order to hasten the growth and maturity of a slowly ripening cataract, many methods have been resorted to, some of which are of considerable antiquity. Some such method is especially desirable in cataracts, which, after a certain indefinite period of steady growth, come to an apparent stand-still. It is well known that, a long while ago, it was proposed to needle the anterior capsule through the cornea; but this method, though fairly successful in very young patients, is unsatisfactory and at times dangerous when applied to mature adults. Snellen's observation, that an iridectomy frequently increases the opacity already existing in a lens, has also been familiar to ophthalmic surgeons, and the operation has therefore been frequently performed to that end. This effect of an iridectomy in sometimes hastening the growth of a cataract is thus explained by Förster: "By the escape of the aqueous humor the lens advances, and in so doing changes its form, while the shifting of its elements within the closed capsule produced by this change of form increases the disintegration of the already loosened fibers." A modification of this operation was proposed by Professor Förster at the Heidelberg Ophthalmological Congress in 1881, and, in the discussion that followed, it was found that his views as to its advantage were indorsed by several members, among them Samelsohn, who had done a similar operation for a number of years. As is well known, the operation, as recommended by Förster, consists in making a broad iridectomy, usually upward, and, after all bleeding has ceased, making a stroking or rubbing massage-pressure upon the cornea opposite the coloboma with the elbow of a strabismus-hook or some similar smooth instrument. The effect which can be produced through the cornea upon the lens in this way is very considerable. A partially opaque lens has been observed, after this operation, to increase very rapidly in opacity, so that, within a period varying from a few hours to a few days or weeks, the entire lens becomes opaque, and is then fit for extraction. Förster recognizes the fact that this method of artificial ripening is not adapted to all cases of unripe cataract, and that a hardened opaque nucleus is absolutely essential. The

* Read before the Ophthalmological Section of the American Medical Association, Washington, May 7, 1884.

writer has found it especially applicable to the very slowly ripening cataracts of middle life and the immature senile cataracts with yellow nucleus and cloudy cortex. The operation will prove a failure unless a hardened opaque nucleus is already present. It should not be forgotten that the cortex of a lens thus rendered opaque by artificial means is soft and not hard, like that of a senile lens, which has become mature by natural processes. Another point to be remembered in the performance of this operation is the proper gauging of the amount of pressure to be exerted upon the cornea, and this, probably, can only be learned by experience. Too strong a pressure would certainly tend to rupture the zonula, and cause a dislocation of the lens. Another danger which the writer has seen result from this massage manœuvre is a striated or radiating opacity of the cornea, which seems to be confined to the anterior layers, frequently remains for a long period, and fades out but slowly. This is no doubt due to some molecular change produced by the massage. If the cornea of a patient be closely watched while the rubbing movement is being carried out, it will be seen that the cut edges of the iris-coboma recede from each other, so that the space grows wider, and also that the margin of the pupil opposite the coboma recedes toward the periphery of the iris. Förster recommends that the rubbing or stroking manœuvre should be from the center of the cornea toward the periphery. The writer has found that a rotatory rubbing or massage answers better, and is, perhaps, more easily and quickly done. One not infrequent result of this operation is a mild form of iritis, which may lead to the formation of posterior synechie, though usually this may be prevented. Förster has never seen iritis follow, although he reports one hundred and fifty cases in which the operation was done; but the writer has seen it a number of times, though slight, and always amenable to treatment. Samelsohn limits the applicability of the operation to those cases in which there was a relatively small and soft nucleus, occurring in patients not over fifty years of age, and he found that the opacity extended much more rapidly if the anterior chamber was absent for several days by reason of the external wound remaining open. This observation the writer can also confirm from a careful examination of a number of cases. There is no doubt that, if care be taken in choosing the cases for this manœuvre and in the amount of pressure exerted, we have a valuable means at our disposal for cutting short the groping period of blindness of a large number of cataractous patients, and of hastening the period when an extraction can be made with good prospects of useful vision. The writer considers the danger which may arise from dislocation of the lens to be very slight. He recognizes a complication in the undoubted cases of iritis which occur, but he has never seen a severe case following the operation, nor one which could not be controlled by the ordinary means. When adhesions occur between the iris and the capsule of the lens, they may be broken by atropine, or by the alternate use of atropine and eserine, or by the forceps or blunt hook, at the subsequent operation for the removal of the cataract. In scarcely any case does the rubbing or massage manœuvre complicate or retard the ordinarily rapid

healing of the iris and wound after a simple iridectomy. The pain is very slight, and the operation can almost always be done without an anæsthetic.

The writer's experience in this operation is limited to thirty cases, extending over a period of about eighteen months. All of these cases belonged either to the class of slowly ripening or stationary nuclear cataracts of middle life, or to the class of immature senile cataracts with hard, yellow nucleus and partially cloudy cortex. In five of these cases the operation was followed by a slight plastic iritis, which readily yielded to ordinary treatment. In no case of the thirty was the zonula ruptured or the lens dislocated. In no case was there a loss of the eye following the later operation for the extraction of cataract. In only three cases was the resulting vision less than $\frac{20}{100}$. In ten cases, or $33\frac{1}{3}$ per cent., the vision after extraction was $\frac{20}{100}$. In the remaining seventeen cases the vision ranged between $\frac{20}{100}$ and $\frac{20}{100}$. In no case was the preliminary operation for ripening the cataract performed, except on account of the extreme urgency demanded for the restoration of useful vision within as short a time as possible. The average duration of hospital or house confinement after the first operation was six days. The period of apparent complete ripening of the cataract after the preliminary operation varied between six days and five weeks. In no case was the extraction of the cataract attempted until four weeks had elapsed after the first operation.

THE FUNDAMENTAL PRINCIPLES OF MECHANICO-THERAPY IN HIP DISEASE.*

By MILTON JOSIAH ROBERTS, M.D.,

PROFESSOR OF ORTHOPÆDIC SURGERY AND MECHANICAL THERAPEUTICS IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL; VISITING ORTHOPÆDIC SURGEON TO THE CITY HOSPITALS ON RANDALL'S ISLAND; PROFESSOR OF ORTHOPÆDIC SURGERY IN THE UNIVERSITY OF MONTREAL, ETC.

(Continued from page 491.)

PHYSICO-PHYSIOLOGICAL THERAPEUTIC DATA.

It will have been observed ere this that the path along which research in mechanico-therapy lies does not come to an end with the observation and careful consideration of clinical phenomena. Nor does it terminate with a knowledge of the site, extent, and nature of the morbid processes. It leads us beyond, to the study of the conditions of life in health, with special reference to those conditions of life in disease which we have observed at the bedside and verified at the post-mortem table. Standing, then, on the firm footing of a thorough familiarity with the clinical features of hip disease, and being assured of the favorable condition of the tissues of the disabled member for the practical execution of the therapeutic ideas which our clinical studies have inspired, let us seek to investigate those physiological questions which have a direct bearing on the ground gone over.

The one fact which our clinical observations have all the way along made paramount in our minds is that the hip-diseased patient requires artificial protection from disastrous traumatism; and, furthermore, that efforts to avert such

traumatisms must have special reference to protecting the area of tissue involved by the disease. That it shall be possible for us to proceed intelligently along this path, we must first know the source of such traumatisms. If the diseased area were located upon the external surface of the body, a very evident source would be direct contact with irritating substances, or blows on the affected area. Though it is not difficult to see how a direct injury to such an exposed focus of disease might result from voluntary muscular efforts, it is equally clear that the traumatisms to which it would be exposed must originate, for the most part, externally to the body. But the diseased area is not so situated. It is buried deeply beneath the soft parts in the head of the thigh-bone, away from the kind of traumatisms which superficial ulcerations of the soft parts fall heir to. Whence, then, come the traumatisms which it is the aim of treatment to nullify?

I think it will be universally granted that clinical studies have established the fact that it is during the act of walking that the hip-diseased patient receives the traumatisms which for the most part prove so disastrous to him. Those due to terrestrial and other forms of transportation, though important to avoid, have a minor significance in this connection, for whatever means will successfully avert the former, experience has taught will nullify the evil influences of the latter. It is, then, to the traumatisms of locomotion, or those resulting from the development of internal forces by an act of volition, that we must direct our attention. Our primary object will be to get some idea of the physical manifestations of these traumatic forces, together with a knowledge of the physical laws which preside over their destinies.

Physiological Dynamics. The Laws of Motion.—Turning our attention to the human body as a whole, recalling our individual observations and experiences, and applying the universally accepted laws of physics regarding the states of rest and motion, the following facts become manifest:

The first of these is, that the body, being at rest, can not be set in motion or transported from one place to another without the application of *force*; likewise, the body being in a state of independent or artificial motion, either in respect to its individual parts or in passing from place to place, it can not be brought to rest without again applying force.

Now, an established law of physics declares that *the application of this force can only take place through the mediation of some external body*. Internal forces can change the relative position of the particles of the body, but they are powerless to independently modify the position of the body as a whole. A man can not walk himself across the street, but is obliged to use the pavement, ground, or some other object external to himself.

Though it is not possible for the position of the body as a whole to be changed without the agency of some external force, it is possible, upon the application of internal force, to throw one part of the body in one direction and another in the opposite direction. At first thought it may not appear perfectly clear how this is possible, but a little reflection upon what takes place during the act of walking will suffice to establish the truth of the statement. In the

act of walking, each leg is successively placed before its fellow, and the body is carried forward. It is generally stated by writers on bipedal locomotion that each step has two phases—one of *impact*, and one of *support*. To these it is necessary to add a third phase, viz., *the application of internal force in a backward direction*.^{*} As the foot meets with resistance upon the ground, and the body has at this instant a forward inclination, the application of internal force in a backward direction simultaneously results in a throwing of the body forward, or in the opposite direction from that in which the force is applied, and the truth of our statement becomes manifest. That the limbs are thus thrown out in opposite directions implies that they move with a given *intensity*. Now, upon the intensity of this action or movement and the bulk of the parts depends the *quantity of motion*, or *momentum*, as it is variously called. Again, applying one of the accepted laws of physics, we find that, whenever motion is developed from the application of internal force, the momentum of the parts moving in opposite directions is the same; or, to put it in more familiar terms, action and reaction are equal and opposite.

The Conservation of Force (Energy).†—When we observe a man walking along the street, the movements continually developed for this purpose are arrested with each successive impact of the foot against the earth, and the force which produces them is apparently annihilated. But let us see if this is really the case. Is it any more feasible to create and annihilate force at pleasure than it is to create and annihilate matter? Nothing can be more certain than that visible motion has been arrested with each successive impact of the foot against the earth, and that a reapplication of internal force was necessary to produce successive movements. If, however, the subject of our observation

^{*} This application of force is at first voluntary, but, once inaugurated, becomes automatic.

† In the present discussion, for reasons which will become evident as I proceed, I shall ignore altogether the one fact which is almost exclusively dwelt upon by writers on physics when it is sought to show that the energy of moving bodies is not destroyed by impact which arrests their motion. The fact referred to is the conversion of visible motion into heat in consequence of collision. Since Grove's first essay on "The Correlation of Physical Forces," the tracing of the sequences of impact has been confined to variously illustrating this fact, to which he was among the first to call attention, while the mechanical effects represented by the molecular vibrations in the colliding bodies have been almost wholly overlooked. In physiological physics a knowledge of these effects is of much greater practical importance in giving a clear insight into the subject—at least in its bearings on mechanical surgery—than are the less apparent thermic changes.

In studying the nature, cause, and effects of jars with reference to the human body, one is naturally led to expect material aid from a study of the laws of sound, for it is common knowledge that it is the vibrations of strings, membranes, and strips of metal and glass which result in producing musical notes or tones. With these effects of vibratory impulses, however, we have nothing to do. Those that concern us do not cause the vibrating bodies to communicate a part of their motion to the surrounding air in such a way as to give rise to audible undulations of it, producing sound. Curiously enough, almost the only analogous effects of vibrations to those that interest us which have been subjected to scientific observation and experiment are of seismic origin. We have, then, come upon a line of dynamic research which promises large returns to scientific medicine.

walks heavily across the floor of the room in which we are sitting, a vibratory impulse is communicated to us, showing that, though visible motion was arrested by the impact of the feet against the floor, the force represented by the movements of the limbs was not annihilated, but underwent a transformation, after which it made itself manifest by a series of vibratory impulses or jars, imparted to objects external to the individual.

Again, suppose, instead of observing some one else, we direct attention to ourselves during the act of walking upon a level piece of earth, it being understood that our feet are clad in ordinary leathern shoes. By so doing we shall be able to appreciate a slight jar communicated to our body at every step. This jarring is so slight as to be unnoticed in health, unless particular attention be paid to it. By flexing the joints of the lower extremities to a greater degree than in ordinary locomotion, the jarring will be rendered almost imperceptible, even though particular attention be paid to detecting it. If, instead of walking on the ground, we walk in the ordinary way upon a stone pavement, the jarring will be much more apparent than in walking on the earth. Still more perceptible will it be if we do not flex our knee and ankle joints, so that we walk "stiff-legged," as it is termed. And, instead of walking on the stone pavement, should we increase our pace and run, we shall find the amount of jarring or shock to the body has been materially augmented. From these and the foregoing observations we are enabled to see that—

*The visible rectilinear velocity of the limbs during locomotion is converted by impact into molecular vibrations (known in common parlance as jars), which are imparted by the individual to the surface walked upon, and reciprocally imparted to and conducted back along the bony framework of the body with each successive step.**

These commonly observed, reciprocal, kinetic sequences of the successive impacts of the feet against the earth serve to illustrate, in a very meager way to be sure, the now universally accepted hypothesis, among scientists, that the various manifestations of energy are correlated, and that force is indestructible. Hence we are justified in the assertion that, though there has been a transformation of force, the resulting mechanical effects of impact, summed up, point to the verifiable existence of an equivalency of energy.

Vibratory Impulses, or Jars, when severe or too long continued, prove Disastrous to Healthy Tissues.—But let us regard still more fully the traumatisms resulting from voluntary muscular efforts. If the subject of our observation, instead of walking along the stone pavement, executes a series of jumps on two feet, he will find the jarring communicated to the body will be decidedly unpleasant, and, if continued long enough, will result in damage to healthy tissues. Or, again, should he engage in a severe contest of locomotor endurance, prolonged for five or six days, without sufficient sleep to permit of physiological repair, an acute synovitis of one or more of the joints of the lower extremi-

ties would probably result. Likewise, if he jumps from a great height to the ground, the resulting shock may even cause a fracture of some of his bones. From these and other observations which will readily present themselves to the mind, it follows that healthy tissues, though plainly in a less degree than diseased tissues, require protection from the vibratory traumatisms resulting from voluntary muscular action.

Again pausing to take our bearings and to see whither the path leads along which we have ventured, the probability becomes emphatically manifest that, by studying the means by which protection of healthy tissues from such traumatisms is normally accomplished, we may get some useful hints in regard to artificially furnishing protection to diseased tissues or joints, that being the goal for which all are striving. But we can not enter at once upon this inquiry. We must first pass over the ground which lies between us and it.

The Conduction of Jars through the Human Body.—For jars or vibratory impulses to damage healthy or diseased tissues, remote from the points of primary impact or collision with external bodies, implies that they shall be *conducted* through the body. By studying the conditions upon which the conduction of jars through the body depends, we again have promise of tangible data for therapeutic purposes.

To make the problem as simple as possible, let us study the conduction of jars through the body in repose. We have already incidentally regarded this point, when observing what took place when the body was in motion. First, let us inspect the healthy individual in the erect attitude, bearing equal weight on both feet. As he poses thus, we find the joint angles obliterated, and there is presented what is practically an unbroken column from the vertex to the soles of the feet. The long bones are placed end to end, so as to form nearly straight lines, and the curves of the spinal column are reduced to the minimum.

Under these circumstances the proportion of the weight of the body borne by the distal articular surface or surfaces of any particular joint varies inversely as the position of that joint in the series, proceeding from the soles of the feet toward the head.

From a study of intra-articular anatomy we learn it is in the erect position also that the greatest possible expanses of distal and proximal articular areas in the different joints of the body which can be utilized at any one time for sustaining the weight of the individual are firmly coaptated. In other words, the areas of contact between the ends of the long bones and those between the segments of the spinal column reach their maximum extent when the individual assumes the erect posture.

There is a twofold significance to this fact which only requires to be pointed out that you should appreciate it. In the first place, there results an equitable distribution of the weight of the head and thorax between the vertebral bodies and their respective articular processes, while in each of the joints of the lower extremities the full quota of the superimposed weight of the body is fairly distributed over the maximum expanse of epiphyseal impingement. Sec-

* *Jars.*—The term jar is used to express not only a particular kind of sensation, which is appreciated more particularly by the sense of touch, but also the state or condition of matter which produces this sensation.

only, as a result of the coaptation of the largest expanse of articular areas and the equitable disposition of the superimposed weight, we have the most *intimate and direct* contact of individual bones attainable in the human subject.

Opposed to the erect position, we have that in which the entire body is thrown into exaggerated curves and angles. The maintenance of such an attitude implies the coaptation of the least possible extent of articular contours. Not only is this the case in those joints into the formation of which the long bones enter, but also in the segments of the spinal column. By an exaggeration of the curves of the spine, the weight which is borne by the bodies in some of its parts in the erect position will be transferred almost entirely to the articular processes, while the reverse state of affairs will be found to exist in other parts of the spine. As a result, we have, in the first place, an *unequal* distribution of superimposed weight over the joint surfaces; and, secondly, the *least intimate* connection between individual bones attainable in the human subject.

Returning now to the erect attitude, let us make note of a commonplace fact, viz.: That it is in this position, standing squarely on both feet, with the trunk and extremities forming practically an unbroken column, and the greatest possible extent of articular areas applied one to another, that any jarring of the surface upon which the individual is standing, or vertical concussion communicated to the head or shoulders, is most readily appreciated, and, if considerable, causes the greatest amount of discomfort. The degree of concussion which in this attitude can be tolerated without discomfort is surprisingly small, and the amount necessary to damage tissue is not great. All of us have experienced the unpleasant jarring of the body incident to jumping from a slight elevation and alighting erect, or "stiff-legged," as it is sometimes termed.

Let us now inquire into the reason why jars are so readily appreciated in the erect attitude. To satisfactorily answer this question it will be of service to formulate the law governing the conduction of the sequence of impact—vibratory impulses—through the human body. This I venture to state in the following terms:

The mechanical effects resulting from the conduction of jars through media depend upon the density of the media and the directness of their linear continuity; the denser the medium and the more direct its continuity, the greater its conductivity.

It is, then, to the denser or bony parts of the body that we must give our principal attention in studying the conduction of jars through it. In the erect posture, with the long bones placed end to end and the spinal curves approaching as nearly as possible a straight line, we have the maximum degree of linear directness, and, consequently, the maximum degree of skeletal or bone conductivity attainable in the human body. It thus becomes evident why the maintenance of this attitude renders the individual so vulnerable to such traumatisms as jars or concussions.

Nature's Protection against Vibratory Traumatisms.—We have now determined upon the source and the nature of the ordinary traumatisms which are to be avoided in hip disease. We have also learned that when these traumatisms

are severe, or too long continued, healthy tissues may be damaged by them. And, finally, we have discovered the law which governs their transmission through the human body. Following out the legitimate sequence of these analytical findings, it will be our next business to study nature's means of protection against such traumatisms. The time allotted me will scarcely admit of more than mention of some of the more important physico-physiological factors connected with the avoidance of concussion or shock in the human body. The accomplishment of this object, in a greater degree than is possible in the erect posture, is absolutely necessary; otherwise the individual would be unable to successfully cope with the exigencies of every-day life.

Exaggerated Skeletal Curves and Angles as a Means of Protection against Jars.—In the accomplishment of this object, the hinge and ball-and-socket joints of the lower extremities, together with the mobile segmented spinal column, as might be inferred from the law just formulated, play a most important part. For it is by means of these that the direct linear osseous continuity of the erect figure, through the agency of the skeletal muscles, acting under the command of the central nervous system, can, at an instant's warning, be broken and decomposed into exaggerated curves and angles. The conduction of jars through the bones is thereby impeded by the obliquity of the impact of the molecular vibrations at the joint angles very much in the same manner as sound-waves take longer to reach a given point when deflected from side to side than when they go in a direct line. In this way, in proportion as we interfere with the directness of skeletal continuity, do we lessen bone conductivity; and likewise, in the same ratio, do we prevent the unpleasant effects of traumatisms. We thus have a logical and rational physical explanation of the *modus operandi* of exaggerated skeletal curves and angles and joints as a whole in averting the evil effects of the inevitable traumatisms of human existence.

Application of Physico-Physiological Data.—The practical applications which I wish to make of physico-physiological phenomena as they are successively elaborated are twofold. In the first place, they are to be utilized for the purpose of testing the therapeutic value of the prevailing mechanical methods of affording protection to diseased hip joints. In the second place, I shall make use of them, in conjunction with the demonstrable clinical facts and confirmatory pathological evidence already tabulated, as basal factors in the building, it is hoped, of a more rational and scientific system of mechanico-therapy than we now have, not only for the hip joint, but for that extended list of chronic articular ailments which have so long been recognized as presenting an insoluble therapeutic enigma, and yet for the relief of which so much has been said and so little really accomplished.

Therapeutic Inferences derived from a Study of the action of Exaggerated Curves and Angles in averting Jars.—Those of my hearers who have had the patience to follow me, and who are at all familiar with the so-called "principles" of the prevailing methods of treating hip and other joint diseases, will have no difficulty in recognizing the fact that we have already prepared the way, in some measure at

least, for the removal of the mantle from mechanical surgery which has so long and so successfully concealed its leprosy from the eyes of casual and credulous observers.

It may be asked, and I confess, at first blush, with apparent good reasons, Why have you, in considering the therapeutics of hip disease, finding it advantageous to refer to functional and structural articular details, extended the scope of your inquiries so as to include all the joints of the lower extremities and spinal column as well?

My reply is, Had physicians confined their mechanical treatment to the hip in hip disease to the extent, at any rate, of not seriously interfering with the functions of healthy joints, it would not have been necessary for me in this paper to have laid so much stress upon the function of other joints than the hip. But when recognized authorities—as, for instance, in our own country Dr. Lewis A. Sayre, and in Europe Mr. Hugh Owen Thomas—will for years persist in the promulgation of views so illogical and inconsistent that they can neither be harmonized with the clinical facts nor with each other, the time has come when some one possessing the courage of his convictions should step to the front in the name of progressive medicine, with a few pertinent correlated facts, in the hope of opening the eyes of credulous hero-worshippers and other willing victims of delusive and unsubstantiated assertions.
